BERRY or **BERRI**, a former province of France, absorbed in 1790 in the departments of Cher, corresponding roughly with Haut-Berry, and Indre, representing Bas-Berry. Berry is the *civitas* or *pagus* Bituricensis of Gregory of Tours. It had been amalgamated with Aquitaine under Augustus with Bourges, as the capital of Aquitania Prima. In 475 Berry came into possession of the west Goths, from whom it was taken (c. 507) by Clovis. The first count of Berry, Chunibert (d. 763), was created by Waifer, duke of Aquitaine, from whom the county was wrested by Pippin the Short, who made it his residence and left it to his son Carloman, on whose death it fell to his brother Charlemagne. The chief authority within the province eventually passed to the viscounts of Bourges, who, while owning the royal suzerainty, preserved a certain independence until 1101, when the viscount Odo Arpin de Dun sold his fief to the Crown. Berry was part of the dowry of Eleanor, wife of Louis VII., and on her divorce and remarriage with Henry II. of England it passed to the English king. Its possession remained, however, a matter of dispute until 1200, when Berry reverted by treaty with John of England to Philip Augustus, and the various fiefs of Berry were given as a dowry to John's niece, Blanche of Castile, on her marriage with Philip's son Louis (afterwards Louis VIII.). Philip Augustus established an effective control over the administration of the province by the appointment of a royal *bailli*. In 1360 Berry was created into a duchy for John, son of John II. of France. Thenceforward it was held as an apanage of the French crown, usually by a member of the royal family closely related to the king. In 1601 it was finally reabsorbed in the royal domain.

BERRYER, ANTOINE PIERRE (1790-1868), French advocate, was the greatest Legitimist advocate of his time. Admitted advocate in 1811, he followed Louis XVIII. to Ghent during the Hundred Days of 1815. On his return he advocated moderation in the treatment of the Bonapartists. He was associated with his father and Dupin in the defence of Marshal Ney, and undertook alone the defence of Generals Cambronne and Debelle. He also stood out as a bold advocate for the freedom of the press, and opposed the rigorous repression exercised by the police department. After the revolution of 1830 he was elected to the Chamber, and championed the cause of the duchess of Berry, but when she landed in the south of France to attempt to set her son, the duke of Bordeaux (afterwards known as the comte de

Chambord) on the throne, he tried to dissuade her from the attempt. Berryer then started for Switzerland; he was arrested and brought to trial, but immediately acquitted. In 1833 he pleaded for the liberation of the duchess, and made a memorable speech in defence of Chateaubriand, besides defending various Legitimist journalists in the courts. He also defended Louis Napoleon in 1840 after the affair of Boulogne.

Berryer was a member of the National Assembly after the revolution of 1848, and continued to fight in the Legitimist cause. He protested against the *coup d'état* of Dec. 2, 1851, and with this great speech his parliamentary career ended, but 12 years later he appeared as a deputy to the Corps Législatif. In 1865 he visited London as the guest of Lord Brougham. At a banquet given in his honour by the benchers of the Temple and Lincoln's Inn famous speeches were delivered by Brougham and Alexander Cockburn on the ethics of advocacy, when Brougham supported what may be called the absolute and Cockburn the qualified or moderate theory. Antoine Berryer died at Augerville on Nov. 29, 1868.

BERSAGLIERI, the name given to the rifle battalions of the Italian army (from Italian *bersaglio*, a mark). The first Bersagliere units were raised in 1836, and by the time of the Crimean War they numbered ten battalions. Their resplendent uniform combined with their excellent record in the various Italian campaigns from the Crimea down to the World War to render them perhaps the most famous and certainly the most popular corps in the army. After the war they were converted into cyclist units, and the number of battalions was fixed at twelve.

BERSERKER, in Scandinavian mythology, the name of the twelve sons of Berserk, grandson of the eight-handed Starkadder and Alfhlide (from the "sark" or shirt of bearskin worn by them). Berserk was famed for the reckless fury with which he fought, always going into battle without armour. In Old Norse the term *berserker* was later applied to the bodyguards of several of the Scandinavian heroes.

BERT, PAUL (1833-1886), French physiologist and politician, was born at Auxerre (Yonne). He was appointed professor of physiology successively at Bordeaux (1866) and the Sorbonne (1869). In 1874 he was elected to the Assembly, where he sat on the extreme left, and in 1876 to the chamber of deputies. He was one of the most determined enemies of clericalism, and an ardent advocate of "liberating national education from religious sects, while rendering it accessible to every citizen." In 1881 he was minister of education and worship in Gambetta's short-lived cabinet, and created a sensation by a lecture on modern Catholicism, delivered in a Paris theatre, in which he ridiculed the fables and follies of the chief religious tracts and handbooks that circulated especially in the south of France. Early in 1886 he was appointed resident-general in Annam and Tongking, and died of dysentery at Hanoi, Nov. 11, of that year. But he was more distinguished as a man of science than as a politician or administrator. His classical work, *La Pression barométrique* (1878), embodies researches that gained him the biennial prize of 20,000 francs from the Academy of Sciences in 1875, and is a comprehensive investigation on the physiological effects of air-pressure, both above and below the normal. His earliest researches, which provided him with material for his two doctoral theses, were devoted to animal grafting and the vitality of animal tissue. After about 1880 he produced several elementary text-books of scientific instruction, and also various publications on educational and allied subjects.

BERTANI, AGOSTINO (1812-1886), Italian revolutionist, took part in the insurrection of 1848 and, as medical officer, organized the ambulance service for the Roman republic of 1849. He joined as surgeon the Garibaldian corps in the war of 1859. Upon the arrival of Garibaldi at Naples, Bertani was appointed secretary-general of the dictator, in which capacity he reorganized the police, abolished the secret service fund, founded 12 infant asylums, suppressed the duties upon Sicilian products, prepared for the suppression of the religious orders, and planned the sanitary reconstruction of the city. Entering Parliament in 1861, he opposed the Garibaldian expedition, which ended at Aspromonte, but nevertheless tended Garibaldi's wound with affectionate devo-

tion. In 1866 he organized the medical service for the 40,000 Garibaldians, and in 1867 fought at Mentana. In Parliament he became leader of the extreme left, and his chief work as deputy was an inquiry into the sanitary conditions of the peasantry, and the preparation of the sanitary code adopted by the Crispi administration.

BERTAT, Negroes of the Shangalla group of tribes, mainly agriculturists, known to the Arabs as *Jebalain*. They occupy the valleys of the Yabus and Tumat, tributaries of the Blue Nile. They are shortish and very black, with projecting jaws, broad noses and thick lips. By both sexes the hair is worn short or the head shaved; on cheeks and temple are tribal marks in the form of scars. The huts of the Bertat are circular, the floor raised on short poles. Their weapons are the spear, throwing-club, sword and dagger, and the *kubeda* or throwing-knife. Blocks of salt are the favourite form of currency. Gold washing is practised. Nature worship still struggles against Mohammedanism. Among them are Arab communities governed by their own sheiks, while the *meks* or rulers of the Bertat speak Arabic, and show traces of foreign blood.

See Koeltitz, "The Bertat," *Journal of the Anthropological Institute*, xxxiii. 51; *Anglo-Egyptian Sudan*, edited by Count Gleichen (1905).

BERTAUT, JEAN (1552-1611), French poet, was born at Caen in 1552. He figures with Desportes in the disdainful couplet of Boileau on Ronsard:

Ce poète orgueilleux, trébuché de si haut,
Rendit plus retenus Desportes et Bertaut.

He wrote light verse to celebrate the incidents of court life in the manner of Desportes, but his verse is more fantastic and fuller of conceits than his master's. He was successively councillor of the parlement of Grenoble, secretary to the king, almoner to Marie de' Medici, abbot of Aulnay, and finally, in 1606, bishop of Sées. After his elevation to the bishopric he ceased to produce the light verse in which he excelled, though he prepared a new edition of his *Recueil de quelques vers amoureux* (1602) in 1606. His works were edited by M. Ad Chenevières in 1891.

BERTH, originally a nautical term, probably connected with the verb "to bear," first found in literature at the end of the 16th century, with the alternative spelling "birth." Its primary meaning is "sea-room," whether on the high seas or at anchor. Hence the phrase "to give a wide berth to," meaning "to keep at a safe distance from."

From meaning sea-room for a ship at anchor, "berth" comes to mean also the position of a ship at her moorings ("to berth a ship"). The word further means any place on a ship allotted for a special purpose, where the men mess or sleep, or an office or appointment on board, whence the word has passed into colloquial use with the meaning of a situation or employment. From the Icelandic *byrdi*, a board, is also derived the ship-building term "berth," meaning to board, put up bulk-heads, etc.

BERTHELOT, MARCELLIN PIERRE EUGÈNE (1827-1907), French chemist and politician, was born at Paris on Oct. 29, 1827, being the son of a doctor. In 1851 he became a member of the staff of the Collège de France as assistant to A. J. Balard, his former master, and about the same time he began his lifelong friendship with Ernest Renan. In 1854 he made his reputation by his doctoral thesis, *Sur les combinaisons de la glycérine avec les acides*, which described a series of beautiful researches in continuation and amplification of M. E. Chevreul's classical work. In 1859 he was appointed professor of organic chemistry at the École Supérieure de Pharmacie, and in 1865 he accepted the new chair of organic chemistry, which was specially created for his benefit at the Collège de France. He became a member of the Academy of Medicine in 1863 and ten years afterwards entered the Academy of Sciences, of which he became perpetual secretary in 1889 in succession to Louis Pasteur. He was appointed inspector-general of higher education in 1876, and after his election as life senator in 1881 he continued to take an active interest in educational questions, especially as affected by compulsory military service. In the Goblet ministry of 1886-87 he was minister of public instruction, and in the Bourgeois cabinet of 1895-96 he held the portfolio for foreign affairs. His

scientific jubilee was celebrated in Paris in 1901. He died suddenly, immediately after the death of his wife, on March 18, 1907, at Paris, and with her was buried in the Panthéon.

He vigorously opposed the generally accepted belief that the formation of organic substances required the intervention of vital activity. His investigations on the synthesis of organic compounds were published in numerous papers and books, including *Chimie organique fondée sur la synthèse* (1860) and *Les Carbures d'hydrogène* (1901). Again he held that chemical phenomena are not governed by any peculiar laws special to themselves, but are explicable in terms of the general laws of mechanics that are in operation throughout the universe; and this view he developed, with the aid of thousands of experiments, in his *Mécanique chimique* (1878) and his *Thermochimie* (1897). This branch of study naturally conducted him to the investigation of explosives, and on the theoretical side led to the results published in his work *Sur la force de la poudre et des matières explosives* (1872), while on the practical side it enabled him to render important services to his country as president of the scientific defence committee during the siege of Paris in 1870-71 and subsequently as chief of the French explosives committee.

His other works include: *Les Origines de l'alchimie* (1885); *Introduction à l'étude de la chimie des anciens et du moyen âge* (1889); publishing translations of various old Greek, Syriac, and Arabic treatises on alchemy and chemistry (*Collection des anciens alchimistes grecs*, 1887-88, and *La Chimie au moyen âge* (1893); *Science et philosophie* (1886), which contains a well-known letter to Renan on "La Science idéale et la science positive"; *La Révolution chimique, Lavoisier* (1890), *Science et morale* (1897), and numerous articles in *La Grande Encyclopédie*, which he helped to establish.

BERTHELOT, PHILIPPE (1866-), French diplomat, son of the great chemist, Marcellin Berthelot, was born on Oct. 9, 1866, at Sèvres. Entering the diplomatic service in 1889, he went, in 1904, to the Foreign Office, where, in 1913, he became assistant-director in the political and commercial department. In this position he did much good work during the days preceding the outbreak of the World War in 1914. During the war he acted as liaison officer between the Allied staffs, and he was a prominent figure at the subsequent peace conferences. In 1919 he was promoted head of the political department, and in the following year became secretary-general to the ministry of foreign affairs with the rank of an ambassador. A year later he became involved in the crisis that overwhelmed the Industrial Bank of China, and was accused in the Chamber of having used his position to assist the bank, of which his brother was a leading director. He resigned on Dec. 27, 1921. In March 1922 he was arraigned before a *Conseil de Discipline*, presided over by M. Poincaré, and was sentenced to ten years' suspension from the service. In May 1924, when the embassy in London fell vacant, his name was among those mentioned for the post. When M. Herriot assumed office in Feb. 1925, it was decided that M. Berthelot might be permitted to take advantage of the amnesty law; and on April 28 he was reappointed to the secretary-generalship. In the following August he accompanied M. Briand to London to resume discussions on the Security Pact, and he was a co-delegate with Briand at the Locarno Conference. At the close of that year he conducted important negotiations with M. Chicherin for a resumption of Franco-Russian relations. A month later, Jan. 1926, owing to a reorganization in the Foreign Office, the virtual control of the political directorate passed into his hands. He had been made a Grand Officer of the Legion of Honour in Dec. 1925. His policy, as he himself voiced it, has always been to be "a faithful practiser of a policy of close union with England and of *rap-prochement* with Germany."

BERTHIER, PIERRE ALEXANDRE, prince of Neuchâtel (1753-1815), marshal of France and chief of the staff under Napoleon I., was born at Versailles on Feb. 20, 1753. During the Revolution, as chief of staff of the Versailles national guard, he protected the aunts of Louis XVI. from popular violence, and aided their escape (1791). In the war of 1792 he was chief of staff to Marshal Luckner, and fought in the Argonne campaign of Dumouriez and Kellermann. He served in the Vendéan War of 1793-95, and was in the next year made a gen-

eral of division and chief of staff (*major-général*) to the army of Italy, which Bonaparte had recently been appointed to command. His power of work, accuracy and quick comprehension, combined with his long and varied experience and his complete mastery of detail, made him the ideal chief of staff to a great soldier; and in this capacity he was Napoleon's most valued assistant for the rest of his career. He accompanied Napoleon throughout the brilliant campaign of 1796, and was left in charge of the army after the peace of Campo Formio. In this post he organized the Roman republic (1798), after which he joined his chief in Egypt, serving there until Napoleon's return. He assisted in the *coup d'état* of 18th Brumaire, afterwards becoming minister of war for a time. In the campaign of Marengo he was the nominal head of the Army of Reserve, but the first consul accompanied the army and Berthier acted in reality, as always, as chief of staff to Napoleon. At the close of the campaign he was employed in civil and diplomatic business. When Napoleon became emperor, Berthier was at once made a marshal of the empire. He took part in the campaigns of Austerlitz, Jena and Friedland, and was created duke of Valengin in 1806, sovereign prince of Neuchâtel in the same year and vice-constable of the empire in 1807. In 1808 he served in the Peninsular War, and in 1809 in the Austrian War, after which he was given the title of prince of Wagram. Berthier married a niece of the king of Bavaria. He was with Napoleon in Russia in 1812, Germany in 1813, and France in 1814, fulfilling, till the fall of the empire, the functions of "major-general" of the *Grande Armée*. He abandoned Napoleon to make his peace with Louis XVIII. in 1814, and accompanied the king in his solemn entry into Paris. During Napoleon's captivity in Elba, Berthier, whom he informed of his projects, was much perplexed as to his future course, and, being unwilling to commit himself, fell under the suspicion both of his old leader and of Louis XVIII. On Napoleon's return he withdrew to Bamberg, where he died on June 1, 1815. According to some accounts he was assassinated by members of a secret society; others say that, maddened by the sight of Russian troops marching to invade France, he threw himself from his window and was killed. Berthier was not a great commander; but his title to fame is that he understood and carried out his master's directions to the minutest detail. His *Mémoires* were posthumously published (1827).

See M. Strich, *Marschall Alexander Berthier und sein Ende* (1908).

BERTHOLLET, CLAUDE LOUIS (1748–1822), French chemist, was born at Talloire, near Annecy, Savoy, on Dec. 9, 1748. He studied first at Chambéry and afterwards at Turin, where he graduated in medicine. He settled in Paris in 1772. In 1785 he declared himself an adherent of the Lavoisierian school, though he did not accept Lavoisier's view of oxygen as the only and universal acidifying principle, and he took part in the reform in chemical nomenclature carried out by Lavoisier and his associates in 1787. Among the substances of which he investigated the composition were ammonia, sulphuretted hydrogen and prussic acid, and his experiments on chlorine, which he regarded, not as an element, but as oxygenated muriatic (oxymuriatic) acid, led him to propose it as a bleaching agent in 1785. He also prepared potassium chlorate and attempted to use it in the manufacture of gunpowder as a substitute for saltpetre. During the French Revolution he served on many technical committees. After 1794 he was teacher of chemistry in the polytechnic and normal schools of Paris, and in 1795 he took an active part in remodelling the Academy as the Institut National. In the following year he and Gaspard Monge were chosen chiefs of a commission charged with selecting in Italy the choicest specimens of ancient and modern art for the national galleries of Paris; and in 1798 he was one of the band of scientific men who accompanied Napoleon to Egypt, there forming themselves into the Institute of Egypt on the plan of the Institut National. On the fall of the Directory he was made a senator and grand officer of the Legion of Honour; under the empire he became a count; and after the restoration of the Bourbons he took his seat as a peer. In the later years of his life he had at Arcueil, where he died on Nov. 6, 1822, a well-equipped laboratory, which became

a centre frequented by some of the most distinguished scientific men of the time, their proceedings being published in three volumes, between 1807 and 1817, as the *Mémoires de la société d'Arcueil*. Berthollet's most remarkable contribution to chemistry was his *Essai de statique chimique* (1803), the first systematic attempt to grapple with the problems of chemical physics. His speculations, in particular his insistence on the influence of the relative masses of the acting substances in chemical reactions, have exercised a dominating influence on the modern developments of the theory of chemical affinity, of which, far more than T. O. Bergman, whom he controverted, he must be regarded as the founder.

BERTHON, EDWARD LYON (1813–1899), English inventor, was born in London, on Feb. 20, 1813, the son of an army contractor. He first studied medicine, then travelled abroad for some years, and in 1841 entered Magdalene college, Cambridge. He took orders in 1845, and held livings at Fareham and then at Romsey. Always interested in engineering, he made a model of a steamboat with a two-bladed propeller some years before he went to Cambridge, but the Admiralty at that time ridiculed the idea, which was fully worked out by Francis Smith in 1838. At Cambridge he produced what is usually known as "Berthon's log," in which the suction produced by the water streaming past the end of a pipe projected below a ship is registered on a mercury column above. At Fareham he was able to carry on experiments with his log, which was tested on the Southampton to Jersey steamboats; but the British Admiralty gave him no encouragement, and it remained uncompleted. He next designed some instruments to indicate the trim and rolling of boats at sea; but the idea for which he is chiefly remembered was that of the "Berthon Folding Boat" in 1849. This invention was again adversely reported on by the Admiralty. In 1873, encouraged by Samuel Plimsoll, he again applied himself to perfecting his collapsible boat, eventually accepted by the Admiralty. Some of these boats were taken by Sir George Nares to the Arctic, others were sent to General Gordon at Khartum, and others again were taken to the Zambezi by F. C. Selous. Berthon died on Oct. 27, 1899.

BERTILLON, LOUIS ADOLPHE (1821–1883), French statistician, was born in Paris. A doctor by profession, he was one of the founders of the school of anthropology of Paris and was appointed professor of demography there in 1876; he also held the post of director of the statistical office of Paris. His principal work is *Démographie figurée de la France* (1874).

His son JACQUES BERTILLON (1851–1922), French statistician, was principal of the office of statistics, and in 1885 the director of the "Annales de Démographie." He wrote *La Statistique humaine en France* (1880).

ALPHONSE BERTILLON (1853–1914), brother of Jacques, French anthropologist, invented the system of identification of criminals, known as Bertillonage, by means of anthropometry (*q.v.*), which he described in his *Photographie judiciaire* (1890). He was officially appointed in 1894 to report on the handwriting of the *bordercau* in the Dreyfus case, and was a witness for the prosecution before the cour de cassation on Jan. 18, 1899.

BERTIN, a family of distinction in the history of French journalism. **LOUIS FRANÇOIS BERTIN** (1766–1841), known as Bertin *ainé*, was born in Paris on Dec. 14, 1766, and practised journalism during the Revolution. After the 18th Brumaire he founded the *Journal des Débats*. He was suspected of royalist tendencies by the consulate and was exiled in 1801. He returned to Paris in 1804 and resumed the management of the paper, the title of which had been changed by order of Napoleon to that of *Journal de l'Empire*. After the Restoration he supported the monarchy until 1823, when the *Journal des Débats* became the recognized organ of the constitutional opposition. Bertin's support was, however, given to the July monarchy after 1830. He died Sept. 13, 1841. **LOUIS FRANÇOIS BERTIN DE VAUX** (1771–1842), the younger brother of Bertin *ainé*, took a leading part in the conduct of the *Journal des Débats*, to the success of which his powers of writing greatly contributed. He entered the chamber of deputies in 1815, was made councillor of state in 1827, and a peer of France in 1830. The two sons of Bertin *ainé*,

EDOUARD FRANÇOIS (1797-1871) and LOUIS MARIE FRANÇOIS (1801-54), were directors in succession of the *Journal des Débats*.

BERTINORO, OBADIAH, Jewish commentator of the Mishnah, died in Jerusalem about 1500. He much improved the status of Jews in Palestine. His commentary on the Mishnah was translated by Surenhusius (Latin ed., Amsterdam 1698-1703).

BERTINORO, episcopal see, Emilia, Italy, province of Forlì, 8m. S.E. direct of Forlì and 5½m. N. of the station of Forlimpopoli, and 800ft. above sea-level. Pop. (1921) town, 1,630, commune 8,749. On the Apennine foothills, it commands a good view towards the lower Po, and its castle built by Barbarossa stood frequent sieges. Polenta, 2½m. to the south of it, was the birthplace of Francesca da Rimini. The castle is almost entirely ruined, but the Lombard church of S. Donato, with Byzantine capitals, is interesting.

See C. Ricci, "Della Chiesa e castello di Polenta" in *Atti e Memorie della Deputazione di Storia patria per le provincie di Romagna*, Ser. iii., vol. ix. (Bologna, 1891), i. seq.

BERTOLD (1442-1504), elector and archbishop of Mainz, son of George, count of Henneberg, was made archbishop of Mainz in 1484. He was an enemy of clerical abuses and a careful administrator of his diocese. Immediately after his election as archbishop he began to take a leading part in the business of the empire, and in 1486 was very active in securing the election of Maximilian as Roman king. During the reign of the emperor Frederick III. he had brought the question of administrative reform before the diet, and after Frederick's death, when he had become imperial chancellor, he was the leader of the party which pressed the necessity for reform upon Maximilian at the diet of Worms in 1495. He continued the struggle at a series of diets, and urged the Germans to emulate the courage and union of the Swiss cantons. He gained a temporary victory when the diet of Augsburg in 1500 established a council of regency (*Reichs-regiment*), and in 1502 persuaded the electors to form a union to uphold the reforms of 1495 and 1500. Bertold died on Dec. 21 1504. He was a man of great ability and resourcefulness, and as a statesman who strove for an ordered and united Germany was far in advance of his age.

See J. Weiss, *Berthold von Henneberg, Erzbischof von Mainz* (Freiburg, 1889).

BERTOLD VON REGENSBURG (c. 1220-1272), an outstanding preacher of his day, was a native of Regensburg (Ratisbon), where he became a Franciscan. From about 1250 onwards his fame as a preacher spread over all Germany, for the earnestness and straightforward eloquence with which he insisted that true repentance came from the heart, that pious pilgrimages and absolution were mere outward symbols, appealed to all classes. He died in Regensburg on Dec. 13, 1272. His German sermons, which reflect the life of the people, form the chief monuments of Middle High German prose; his Latin ones are written in a clear and direct style. The former were edited by F. Pfeiffer and J. Strobl (2 vols., 1862-80, reprinted 1906) and also exist in a modern German version by F. Göbel (4th ed. 1906); the latter were edited by G. Jakob (1880).

See C. W. Stromberger, *Bertold von Regensburg, der grösste Volksredner des deutschen Mittelalters* (1877), E. Bernhardt, *Bruder Bertold von Regensburg* (1905); A. E. Schonbach, *Studien zur Geschichte der alldutschen Predigt* (Publications of the Vienna Academy, 1900, 1904, and 1906).

BERTRAM, CHARLES (1723-1765), English literary impostor, was a teacher of English at Copenhagen. He announced his discovery of a ms. written by Richard of Westminster which corrected and supplemented the *Itinerarium* of Antoninus in Britain, and produced a forgery which was generally accepted as genuine until 1866, when the imposture was exposed in the *Gentleman's Magazine*. The document was included in Bertram's *Britannicarum Gentium Historiae Antiquae Scriptores Treo* (1757).

BERTRAND, HENRI GRATIEN, COMTE (1773-1844), French general, friend and confidant of Napoleon I., was born at Châteauroux on March 28 1773, and died there on Jan. 31 1844. At the outbreak of the Revolution he entered the army as a volunteer. During the expedition to Egypt, Napoleon named him colonel (1798), then brigadier-general, and after Austerlitz

his aide-de-camp. His life was henceforth closely bound up with that of Napoleon, who had the fullest confidence in him and made him (1813) grand marshal of the court. Bertrand directed the building of the bridges by which the French army crossed the Danube at Wagram (1809). In 1813, after the battle of Leipzig, his efforts preserved the army from destruction. He accompanied Napoleon to Elba in 1814, returned with him in 1815, held a command in the Waterloo campaign and accompanied Napoleon to St. Helena. He returned to France after Napoleon's death. Louis XVIII. allowed him to retain his rank, and he was elected deputy in 1830. In 1840 he was sent to bring Napoleon's remains to France.

BERTRAND, JACQUES-LOUIS-NAPOLÉON ("ALOYSIUS") (1807-1841), French author, was born on April 20, 1807, in Piedmont. His father was French, his mother Italian. In 1815 the family went to live in Dijon, and he was educated at the college there. His early work, done as a member of the Société d'Etudes, was mostly concerned with Burgundy and Dijon and their history, and the early poems in *La Volupté* are of a similar type. In 1828 he became *gérant* of the *Provincial*, a monarchist and Catholic paper, his contributions to which brought him to the notice of Victor Hugo and Sainte-Beuve. He went to Paris in Nov. 1828, and we hear of him at the salons of Hugo and Sainte-Beuve and their circle, especially on one evening when he made a great impression by reciting the *Sire de Maupin*. During this visit to Paris he showed the mss. of *Gaspard de la Nuit* to Sainte-Beuve. Then he went back to Dijon, contributed to the *Spectateur* till it was suppressed under the Ordonnances, and after the revolution of 1830 became editor of the *Patriote de la Côte d'Or*, a liberal and revolutionary paper. He went back to Paris in 1832, where his mother and sister joined him, and they lived in great poverty. He did some journalistic work, failed to get some plays produced, and refused various posts that were offered him. Renduel the publisher bought *Gaspard de la Nuit*, but never published it. By this time Bertrand was desperately ill with consumption; from Sept. 1838 onwards he was in and out of hospital continuously, and he died on April 29, 1841, and was buried at Vaugirard.

Sainte-Beuve describes Bertrand as "a tall young man of 21 with a yellow complexion, very lively little black eyes, a face mocking and sharp, a little wretched perhaps, and a long silent laugh." *Gaspard de la Nuit*, a very rare book, has always been highly valued by a small circle of initiates, and was professedly Baudelaire's model for the *Petits Poèmes en Prose*. The book consists of a series of short sketches, "engravings after imaginary pictures," written in carefully-balanced paragraphs, usually single sentences.

See C. C. Sprietsma, *Louis Bertrand* (1926, bibl.) and the *Fortnightly Review*, vol. 92.

BERTRAND, LOUIS (1866-), French author, was born at Spincourt (Meuse) on March 20, 1866, and lived in Algiers from 1891 to 1900. He was received into the Académie Française on Nov. 26, 1926. In a series of novels and other works, Bertrand depicted the civilization of north Africa. Important examples of his novels are *Le Sang des Races* (1899), *Pépète le bien-aimé* (1904). Other works are *La Fin du Classicisme et le Retour à l'Antique* (1897); *Saint Augustin* (1913). Bertrand believed in the possibility of a renaissance of culture and learning in north Africa through the infiltration of French culture, and that conversely, Africa would give renewed strength to the old civilization of France.

BERULLE, PIERRE DE (1575-1629), French cardinal and statesman, was born at Sérilly, near Troyes, on Feb. 4, 1575. He was educated by the Jesuits and at the University of Paris. He assisted Cardinal Duperron in his controversy with the Protestant Philippe de Mornay, founded the Congregation of the French Oratory in 1611, and introduced the Carmelite nuns into France. Berulle obtained the necessary dispensations from Rome for Henrietta Maria's marriage to Charles I., and acted as her chaplain during the first year of her stay in England. In 1626, as French ambassador to Spain, he concluded the treaty of Monzon. After the reconciliation of Louis XIII. with his mother,

Marie de' Medici, through his agency, he was appointed a councillor of state, but had to resign this office owing to his Austrian policy which was opposed by Richelieu. His treatise, *Des Grands de Jésus*, was a favourite book with the Jansenists. He died on Oct. 2, 1629. His works, edited by P. Bourgoing (1644) were reprinted by Migne in 1857.

See Abbé M. Housaye, *M. de Bérulle et les Carmélites; Le Père de Bérulle et l'oratoire de Jésus; Le Cardinal de Bérulle et Richelieu* (1872-76); H. Sidney Lear, *Priestly Life in France in the Seventeenth Century* (1873).

BERVIE or **INVERBERVIE**, royal burgh, Kincardineshire, Scotland, at the mouth of Bervie Water, terminus of the L.N.E. railway's branch line from Montrose, which lies 14m. S.W. Pop. (1921) 1,041. The leading industry is flax-spinning. Bervie, with Arbroath, Brechin, Forfar and Montrose, returns one member (for the "Montrose burghs") to Parliament. David II., under stress of weather, landed here with his queen Joanna in 1341, and, out of gratitude for hospitality, granted them a charter, which James VI. confirmed. Hallgreen Castle (14th century), is kept in repair. About 1m. south is the fishing village of Gourdon, where boat-building and fish-curing are carried on. St. Ternan's, the Romanesque parish church of Arbuthnott, 2½m. N.W., stands on the banks of the Bervie. In the chapel dedicated to St. Mary, which was afterwards added to it, is the burial-place of the Arbuthnotts. At Kinneff, 2m. N., on the coast, the Scottish regalia were concealed during the siege of Dunottar Castle.

BERWICK, JAMES FITZJAMES, DUKE OF (1670-1734), marshal of France, was the natural son of James, duke of York, afterwards James II. of England, by Arabella Churchill (1648-1730), sister of the duke of Marlborough. He was born at Moulins (Bourbonnais) on Aug. 21 1670, and educated in France. He served his first campaign in Hungary under Charles of Lorraine, and was present at the siege of Buda. He then returned to England, was made a colonel of the 8th Foot, and in 1687 was created duke of Berwick, earl of Teignmouth and Baron Bosworth. The revolution forced him to flee to France. He served under James II. in the campaign in Ireland, and was present at the battle of the Boyne. For a short time he was left in Ireland as commander-in-chief, but his youth and inexperience unfitted him for the post. He then took service in the French army, fought under Marshal Luxembourg in Flanders, and took part in the battles of Steinkirk and Neerwinden, at the latter of which he was taken prisoner. He was, however, immediately exchanged for the duke of Ormond, and afterwards served under Villeroi. In 1695 he married the widow of Patrick Sarsfield, who died in 1698. His second marriage, with Anne Bulkeley, took place in 1700. He served in the campaign of 1702, after which he became naturalized as a French subject. In 1704, he first took command of the French army in Spain, but after one campaign he was replaced by the Marshal de Tessé. In 1705 he commanded against the Camisards (q.v.) in Languedoc, and when on this expedition he is said to have carried out his orders with remorseless rigour. After his successful expedition against Nice in 1706 he became a marshal of France, and returned to Spain as commander-in-chief of the Franco-Spanish armies. On April 25, 1707, the duke won the great and decisive victory of Almanza, where an Englishman at the head of a French army defeated Ruvigny, earl of Galway, a Frenchman at the head of an English army. The victory established Philip V. on the throne of Spain. Berwick was made a peer of France by Louis XIV., and duke of Liria and of Xerica and lieutenant of Aragon by Philip. Thenceforward Berwick was recognized as one of the greatest generals of his time, and successively commanded in nearly all the theatres of war. From 1709 to 1712 he defended the south-east frontier of France in a series of campaigns which, unmarked by any decisive battle, were yet models of the art of war as practised at the time. The last great event of the war of the Spanish Succession was the storming of Barcelona by Berwick, after a long siege, on Sept. 11 1714. Three years later he was appointed military governor of the province of Guienne, in which post he became intimate with Montesquieu.

In 1718 he again entered Spain with an army; and this time he had to fight against Philip V., the king who owed chiefly to Berwick's courage and skill the safety of his throne. Marshal Berwick advised and conducted the siege of Philippsburg, and was killed by a cannon-shot on June 12 1734. Cool, self-possessed and cautious as a general, Marshal Berwick was at the same time not wanting in audacity and swiftness of action. He was a true general of the 18th century, not less in his care for the lives of his men than in his punctiliousness and rigidity in matters of discipline.

The *Mémoires* of Marshal Berwick, revised, annotated and continued by the Abbé Hooke, were published by the marshal's grandson in 1778. Montesquieu made many contributions to this.

BERWICK, a manufacturing borough of Columbia county (Pa.), U.S.A., on the Susquehanna river, 25m. S.W. of Wilkes-Barre. It is served by the Pennsylvania and the Lackawanna railways. The population was 3,916 in 1900; 12,181 in 1920; and was estimated at 14,160 in 1925. It has steel rolling, planing, and flour mills, and manufactures steel cars, nuts, bolts, silk, shirts, knitted goods, auto bodies and food products. The largest plant of the American Car and Foundry Company is here.

BERWICKSHIRE, county, Scotland, forming its south-east extremity, bounded N. by Haddingtonshire and the North Sea; E. by the North Sea; S.E. by the county of the borough and town of Berwick; S. by the Tweed and Roxburghshire, and W. by Mid-Lothian. Its area is 292,535ac. or 457sq. m., and it has a coastline of 21m. The county is naturally divided into three districts; Lammermuir, the upland district occupied by the hills of that name in the north; Lauderdale, or the valley of the Leader, in the west; and the Merse (the March of Borderland, giving a title to the earls of Wemyss), the largest district, occupying the south-east. The Lammermuirs are a range of round-backed hills, whose average height is about 1,000ft., while the highest summit, Says Law, reaches 1,749ft. They belong to the Silurian uplands of southern Scotland. The Silurian strata terminate eastward at St. Abb's head; in this direction, and on the southern flanks of the hills, and in Lauderdale they are overlaid unconformably by old red sandstones. From the Lammermuirs the Merse stretches to the south and east, and is comparatively level country, mainly occupied by the cementstone group of the carboniferous system, which attains a great thickness. The coast is rocky and precipitous, broken by ravines and not accessible, except at Eyemouth Harbour, for small vessels, and at Coldingham and Burnmouth for fishing boats. St. Abb's head, a promontory with a lighthouse upon it, rises to 310ft. The Eye is the only river of any size which falls directly into the sea. The others—the Leader, the Eden, the Leet and the Whiteadder with its tributaries, the Blackadder and the Dye—all flow into the Tweed. Of these the largest and most important is the Whiteadder, which has its source in the parish of Whittingehame on the East Lothian side of the Lammermuirs, and, following a sinuous course of 35m., joins the Tweed within the bounds or liberties of Berwick.

History.—Traces of Roman occupation and early British settlement exist in various parts of the Merse. Edin's or Etin's Hall, on Cockburn Law, 4m. north of Duns, is still called the Pech's or Pict's House, and is one of the very few brochs found in the Lowlands. After the Romans withdrew (409) the country formed part of the Saxon kingdom of Northumbria, and the inhabitants were converted to Christianity through Modan in the 6th, and Oswald, Aidan and Cuthbert (traditionally believed to have been born in the vale of the Leader) in the 7th centuries. The Danes landed in 886, and destroyed the nunnery at Coldingham, founded about 650 by Ebba, daughter of Æthelfrith, king of Northumbria, after whom the adjoining promontory of St. Abb's head was named. After the battle of Carham (1018) the district, then part of Lothian, was annexed to Scotland. Birgham (pron. Birjam), 3½m. west of Coldstream, was the scene of the conference in 1188 between William the Lion and the bishop of Durham, which discussed the attempt of the English church to assert supremacy over the Scottish. Here also met in 1289 a convention of the Scots estates to consider the projected marriage of Prince Edward of England to the Maid of Norway; and here was signed in 1290 the treaty of

Birgham, assuring the independence of Scotland. The ford at the confluence of the Leet and Tweed near Coldstream gave access to south-eastern Scotland. Edward I. crossed it with his army in 1296, encamping at Hutton the day before the siege of Berwick, and it was similarly employed as late as 1640, when the marquess of Montrose led the Covenanters on their march to Newcastle, although James VI. had already caused a bridge to be constructed from Berwick to Tweedmouth. During the long period of international strife the shire was repeatedly overrun by armies of the English and Scots kings, fighting for the ancient frontier town of Berwick. It was finally ceded to England in 1482. Upon the site of the nunnery at Coldingham King Edgar in 1008 founded a Benedictine priory, which was one of the oldest monastic institutions in Scotland and grew so wealthy that James III. annexed its revenues to defray his extravagance, a step that precipitated the revolt of the nobles (1488). The priory was seriously damaged in the earl of Hertford's inroad in 1545, and Cromwell blew up part of the church in 1650. The chancel (without aisles) was repaired and used as the parish church. The remains contain some fine architectural features, such as, on the outside, the Romanesque arcades surmounted by lancet windows at the east end, and, in the interior, the Early Pointed triforium. On the coast, about 4m. north-west of Coldingham, are the ruins of Fast Castle—the "Wolf's Crag" of Scott's "Bride of Lammermoor"—situated on a precipitous headland. Four miles west is the Pease or Peaths bridge, built by Thomas Telford in 1786 across the deep pass which was of old one of the strongest natural defences of Scotland. The bridge is 123ft. high, 300ft. long and 16ft. wide. Near it are the ruins of Cockburnspath Tower, once a strong fortress and supposed to be the "Ravenswood" of the "Bride of Lammermoor." In the south-west of the shire, besides Dryburgh Abbey (*q.v.*) there are, at Earlstoun, remains of the castle traditionally the residence of Thomas the Rhymer. Hume Castle, the ancient seat of the Home family, is a picturesque ruin about 3m. south of Greenlaw. Coldstream and Lamberton, being close to the Border, were both resorted to (like Gretna Green in the west) for clandestine marriages. In Lamberton church was signed in 1502 the contract for the marriage of James IV. and Margaret Tudor, which led, a century later, to the union of the crowns of Scotland and England.

Population and Government.—The population of Berwickshire was 29,643 in 1911 and 28,246 in 1921, in which year the number of persons speaking Gaelic and English was 82. The only considerable towns are Eyemouth (pop. in 1921, 2,477) and Duns (1,868). The county with Haddington, returns one member to parliament. Lauder is the only royal burgh, and Duns the county town, a status, however, which was held by Greenlaw from 1696 to 1853, after which date it was shared by both towns until conferred on Duns alone. Berwickshire forms a sheriffdom with Roxburgh and Selkirk shires, and there is a resident sheriff-substitute at Duns.

Agriculture.—The soils vary, sometimes on the same farm. Along the rivers is a deep rich loam, resting on gravel or clay, chiefly the former. The less valuable soil of the Merse has been much improved by drainage. The more sandy and gravelly soils grow quantities of turnips. Oats and barley are the principal grain crops, but wheat also is raised. The flocks of sheep are heavy, and cattle are pastured in considerable numbers. Large holdings predominate. A migratory tendency noted among the agricultural labourers, which they may have by inheritance as Borderers, has fitted them for colonial life, to which the scarcity of industrial occupation has largely driven the surplus population. The trade of the county is mainly agricultural. The sales of cattle and sheep mostly take place at the auction marts at Reston, Duns and Earlstoun. There are also grain markets at Duns and Earlstoun. Berwick, however, from which the county derives its name, but with which it has no legal or fiscal connection, is its chief market.

Other Industries.—The Tweed salmon fisheries are famous, and the lesser rivers of the Merse are held in esteem by anglers. Eyemouth, Burnmouth and Cove are engaged in the sea fisheries, Eyemouth being the centre of a fishing board district. Haddock, herring, lobsters and crabs are principally taken. There is some quarrying of the sandstones and of certain of the intrusive igneous

rocks which are found in limited areas. Earlstoun produces woollen cloths. At Cumledge on the Whiteadder, blankets and plaids are manufactured, and paper is made at Chirnside and near Ayton.

The L.N.E. railway serves the coast districts from Berwick to Cockburnspath, and there is a branch which runs from Reston to St. Boswells.

BERWICK-UPON-TWEED, municipal borough, county of itself, Northumberland, England, at the mouth of the Tweed on the north bank 339m. N. by W. of London; pop. (1921) 12,985. The east coast route from London (L.N.E.R.) to Scotland crosses the border here. The town lies on the lower slope of bare hills rising from the river on north and south.

Very little is known of the history of Berwick before the Conquest. It was not until the Tweed became the boundary between England and Scotland in the 12th century that Berwick as the chief town on that boundary became really important. Until the beginning of the 14th century Berwick was one of the four royal boroughs of Scotland. After Edward I. had conquered Berwick in 1302 he gave the burgesses a charter, by which the town was made a free borough with a gild merchant, having two markets every week, and a fair. It has been noted for salmon fishery in the Tweed from very early times. James I. granted the incorporation charter in 1604; but on his accession to the English throne, Berwick rapidly lost its importance as a frontier town. The town has the rare feature of a complete series of ramparts surrounding it. The Bell Tower, from which alarms were given when border raiders were observed, is in fair preservation. There are slight remains of the castle, which fell into disrepair after the union of England and Scotland. There are no traces of the churches, monasteries or other principal buildings of the ancient town. Educational institutions include an Elizabethan grammar school. Two bridges connect the town with the south side of the Tweed. The older was finished in 1634; the other, the Royal Border bridge, situated a quarter of a mile up the river, is a railway viaduct, 126 ft. high, with 28 arches. A much larger and wider bridge was erected in 1926.

The reach of the river from the old bridge to the mouth forms the harbour. The entrance to the harbour is protected by a stone pier. Principal exports are grain, coal and fish; imports are bones and bone-ash, guano, phosphate and timber. The herring and other sea fisheries are of some value. A fair is held annually at the end of May. Many of the inhabitants are employed in the coal-mines and ironworks of the neighbourhood.

The custom of mentioning Berwick-upon-Tweed specially after Wales, though abandoned in acts of parliament, is retained in certain proclamations. The title of "county in itself" also helps to recall its ancient history. The liberties of the borough, commonly called Berwick Bounds, include the towns of Spittal, at the mouth, and Tweedmouth immediately above it, on the south bank of the river. Berwick-upon-Tweed is governed by a mayor, 6 aldermen and 18 councillors. Area, 6,396 acres.

Berwick was at first represented in the court of the four boroughs and in 1326 in Robert Bruce's parliament. After being taken by the English it remained unrepresented until it was retaken by the Scots, when it sent two members to the parliament at Edinburgh from 1476 to 1479. In 1482 the burgesses were allowed to send two members to the English parliament, and were represented there until 1885, when the town was included in the Berwick-upon-Tweed division of the county of Northumberland.

BERWYN, a rapidly growing residential suburb of Chicago (Ill.) U.S.A., occupying 3.75 sq. m. in Cook county, 8m. from "the Loop," between Oak Park, Cicero, Forest Park, and Riverside, and served by the Burlington and the Illinois Central railways. Within walking distance are several forest preserves. Building permits for the five years 1923-27 represent values amounting to \$47,000,000. The city has a recreation director. There are six banks and several building and loan associations. The village was laid out in 1890 and incorporated as a city in 1908. The population was 5,841 in 1910; 14,150 in 1920; and was estimated locally at over 50,000 in 1928.

BERYL, the name applied to the species of precious stone including the emerald (*q.v.*), the aquamarine (*q.v.*) and other

transparent varieties known as "precious beryl," with certain coarse opaque varieties unfit for use as gem-stones. The name comes from the Gr. *βήρυλλος*, a word of uncertain etymology applied to the beryl and probably several other gems (see GEMS). Beryl is a silicate of beryllium and aluminium, $\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$; alkalis (Na, K, Li, Cs) sometimes replace Be up to a maximum of 7%. It crystallizes in the hexagonal system, usually taking the form of long six-sided prisms, striated vertically and terminated by the basal plane, sometimes associated with various pyramidal faces. It cleaves rather imperfectly parallel to the base. The colour may be blue, green, yellow, brown, colourless or rarely pink. The specific gravity is about 2.7, and the hardness 7.5 to 8. The transparent crystals are pleochroic—a character well marked in emerald.

Beryl occurs as an accessory constituent of many granitic rocks, especially in veins of pegmatite, while it is found also in gneiss and in mica-schist. Rolled pebbles of beryl occur, with topaz, in Brazil, especially in the province of Minas Geraes. Crystals are found in drusy cavities in granite in the Urals, notably near Mursinka; in the Altai mountains, which have yielded very long prismatic crystals; in the mining district of Nerchinsk in Siberia, principally in the Adun-Chalon range, where beryl occurs in veins of topaz-rock piercing granite; in Cornwall, Ireland, Scotland and other parts of Europe; and in many parts of the United States.

BERYLLIUM or **GLUCINUM**, a metallic element with relationships to magnesium, zinc and aluminium. (Symbol Be, atomic number 4, atomic weight 9.02; no isotopes.) Beryllia was first isolated from beryl in 1797 by Vauquelin, whereas Wöhler, Bussy and Debray were the first to isolate the element itself in impure powder form by the decomposition of its chloride with sodium and potassium. Later, Lebeau obtained this element by electrolysis of a fused mixture of sodium and beryllium fluorides carried out at a comparatively low temperature (incipient red heat) in nickel crucibles, the product being in the form of tiny leafy or fern-like particles. By this process the yield is low, and subsequent refinements neither increased the yield nor improved the purity of the fused metal obtained by melting down the fine particles into a compact mass.

Electro-metallurgy.—Although probably the first preparation of metallic beryllium by electrolysis at a temperature high enough to melt the product is that of Liebmann, yet much more recently Stock and Goldschmidt have produced by more effective methods fairly pure fused metal by high-temperature electrolysis. They electrolyse beryllium fluoride dissolved in a fused mixture of sodium and barium fluorides in a graphite pot with an iron rod dipping into the middle of the melt. The electric current is passed between the pot and the iron rod through the melt so that beryllium is precipitated on the iron, the temperature of the pot being kept sufficiently high to melt the deposit into a compact mass. For pure beryllium a temperature of $1,280^\circ\text{C}$. must be reached and, as there is normally at this temperature a rapid loss by evaporation and not a little commotion in the melt, much experience is required for the satisfactory and continuous working of such a method.

At the National Physical Laboratory, Teddington, England, a process similar in principle to that outlined above has been closely studied for a number of years and the inherent defects have been overcome. This research shows that the production of beryllium by the improved method would cost little more than the analogous process in regular use for the manufacture of aluminium, provided pure beryllia could itself be procured as cheaply as alumina. Useful though beryllium metal would be, it is unfortunate that no very considerable deposit of beryllium minerals has ever been located. The largest deposits as yet known are of beryl containing no more than 4 or 5% of the metal. Absence of demand and difficulty of identification have been responsible for a serious lack of information concerning the occurrence of beryllium minerals. This deficiency should be less felt in the future now that knowledge of the properties both of the element itself and of its various alloys and minerals is increasing.

Properties and Uses.—The application of beryllium as an industrial metal is still in its infancy. The metal is unique in being lighter than aluminium and practically as light as magnesium (sp. gr. 1.84), and having a much higher melting point ($1,280^\circ\text{C}$.), higher corrosion resistance, and greater hardness than either of these elements.

Beryllium is of a dark steel-grey colour; it takes a high polish which, however, appears to have no exceptional reflectivity for white light. Its hardness is evidently dependent to an unusual extent upon its purity, and as prepared at the National Physical Laboratory (99.9% purity), it is as hard as 0.20 carbon-steel, probably owing to this hardness and also its brittleness to some specific impurity. Like aluminium, the metal combines vigorously with many other elements but becomes inert to corrosive and other influences through the formation of a fine protective film of oxide of a very tenacious and inactive nature. Beryllium may be sublimed or distilled rapidly at a temperature not far removed from its melting point.

Alloys with copper, silver, iron, aluminium, etc., have been investigated with interesting results, although much work remains to be done before commercial demands will arise for any of these materials. Its lightness, high melting point, hardness, and heat conductivity point to possible application in the construction of pistons in motor-car and aeroplane engines where cost is a minor consideration. The ductile metal, or a beryllium-rich alloy with some other metal or metals, might supplant aluminium for many purposes where lightness, strength, and corrosion resistance are essential as in all aero-construction. Alloys with iron are being investigated and an untarnishable silver-beryllium alloy has been recorded.

Chemistry of Beryllium.—The Copaux method of extracting beryllium salts from beryl and other silicates is worthy of note in that these refractory minerals are thereby treated cheaply, with remarkable ease, and with a high yield. The method consists in heating at 850°C . a mixture of finely crushed beryl or other mineral and crude sodium silicofluoride (which is a cheap by-product of artificial phosphate manufacture from fluorapatites). Hot water washings dissolve beryllium salts from the mass, leaving in the residue both alumina and silica.

The unique behaviour of beryllium salts in dissolving large quantities of beryllium hydroxide has been put to good account in a novel method for the purification of beryllium solutions and separation of compounds. So remarkable is this property that there are but few salts of beryllium which can be crystallized out of solution, as are the salts of other elements. The usual product of attempted crystallization is a gummy mass of highly "basic" and very variable composition. This peculiarity of beryllium salts has undoubtedly hindered the progress of beryllium chemistry.

Inorganic Compounds of Beryllium.—**Beryllium oxide** (*beryllia*). The compound of beryllium and oxygen is usually obtained as a very refractory white powder which can be volatilized *in vacuo* at a high temperature. A small percentage is contained in the mixture of oxides used in incandescent gas mantles. At the National Physical Laboratory it has been found possible to use beryllia in the form of crucibles for melting and subliming pure beryllium metal without contamination. These crucibles are made by compressing a mixture of beryllia and gum in moulds of the desired shape. After removal from the mould and drying, they are fired in a ceramic kiln to $1,500^\circ\text{C}$.

Beryllium chloride is formed by passing dry hydrogen chloride over the heated metal. It is prepared by the action of the phosphorus chlorides, sulphur chloride, or preferably carbon tetrachloride on beryllia at 700 – 800°C . (C. Matignon and M. Piettre). It is a white, crystalline, hygroscopic solid melting at about 400°C ., and is very soluble in water with formation of hydrochloric acid.

Beryllium iodide, prepared by the action of iodine on the metal in a vacuum at about 300°C ., is a colourless crystalline solid which volatilizes below its melting point (510°C .). It is soluble in water with formation of hydriodic acid. By introducing the vapour of the iodide into an evacuated vessel in which is sus-

pended a thin tungsten wire electrically heated to about 700° C., dissociation takes place into iodine and beryllium, the metal being deposited on the tungsten in a very pure form. The diameter of the wire can be increased by deposition from 0.1 mm. to 4 or 5 mm.

Beryllium fluoride remains as a glassy transparent mass on heating the double fluoride of beryllium and ammonium, and is extremely hygroscopic. The beryllium halides cannot be crystallized from aqueous solutions.

Beryllium sulphate is prepared by the action of sulphuric acid on beryllia. The excess of acid is removed by evaporation, the residue being dissolved in water and poured into alcohol, whereupon the sulphate slowly separates. To ensure freedom from acid, two or more crystallizations from alcohol are necessary, the salt being finally crystallized from water. It consists of colourless crystals containing water of crystallization. Its aqueous solution dissolves large quantities of beryllia when treated with the hydroxide or basic carbonate.

Organic Compounds of Beryllium.—*Basic beryllium acetate* $(\text{CH}_3\text{CO}_2)_2\text{Be}_2\text{O}$, produced by dissolving beryllium hydroxide or basic carbonate in acetic acid, is insoluble as such in water but soluble in such organic solvents as glacial acetic acid, chloroform, ether and alcohol. From these solutions the compound separates in well-defined crystals belonging to the cubic system. These crystals have a definite melting point and can be distilled unchanged under normal or reduced pressure. When subjected to X-ray examination, the component parts of the basic acetate molecule are found to be arranged as follows. The lone oxygen atom is placed centrally, the four beryllium atoms occupy the four vertices of a regular tetrahedron, and the six acetate groups span symmetrically the six sides of this regular solid. Homologues $(\text{R}\cdot\text{CO}_2)_2\text{Be}_2\text{O}$, have also been prepared and examined (Morgan and Astbury, 1926), namely the propionate, *n*- and *iso*-butyrates, and pivalate (trimethylacetate). These derivatives are also readily soluble in organic media.

Beryllium acetylacetonate, another co-ordination compound, is also insoluble in water but soluble in organic solvents; it melts and distils without decomposition. In this substance beryllium is in fourfold association with two ring-forming radicals (chelate groups).

Beryllium benzoylpyruvate, a similar co-ordination compound, has been shown by Mills and Gotts (1926) to exist in two optically active forms, thus establishing the fact that these arrangements of four associating units round beryllium are not uniplanar but tetrahedral. (See STEREO-CHEMISTRY.)

In the foregoing co-ordination compounds, beryllium is not combined directly with carbon but only indirectly through oxygen. True organo-metallic derivatives have, however, been obtained in which the metal is attached directly to one or two organic radicals. Earlier workers (Cahours, 1860, and Lavroff, 1884) have indicated the probable existence of such beryllium compounds, and Gilman and Schulze (1927), by using anhydrous beryllium chloride with the appropriate Grignard reagent (*q.v.*), have definitely identified beryllium dimethyl as a snow-white solid subliming at 200°, and beryllium diethyl as a colourless liquid m.p. 12°, b.p. 110°/15 mm., both being spontaneously inflammable in air. These observers also obtained beryllium di-*n*-butyl and the corresponding diphenyl together with compounds of the type $\text{R}\cdot\text{Be}\cdot\text{X}$, where R is an alkyl or aryl group and X is bromine or iodine. (See ORGANO-METALLIC COMPOUNDS.)

See "Beryllium," *Trans. Faraday Soc.*, xxii. (1926); C. L. Parsons, *The Chemistry and Literature of Beryllium* (1909).
(H. A. S.; A. C. V.)

BERYLLONITE, a mineral phosphate of beryllium and sodium (NaBePO_4), found as highly complex orthorhombic crystals and as broken fragments in the disintegrated material of a granitic vein at Stoneham, Maine, where it is associated with feldspar, smoky quartz, beryl and columbite. The crystals vary

from colourless to white or pale yellowish, and are transparent with a vitreous lustre; there is a perfect cleavage in one direction. Hardness 5½–6; specific gravity 2.845.

BERZELIUS, JÖNS JAKOB (1779–1848), Swedish chemist, was born at Väfversunda Sorgard, near Linköping, Sweden, on Aug. 20 or 29, 1779. He studied chemistry and medicine, and graduated as M.D. in 1802 at Uppsala. Appointed assistant professor of botany and pharmacy at Stockholm in the same year, he became full professor in 1807, and from 1815 to 1832 was professor of chemistry in the Caroline medico-chirurgical institution of that city. The Stockholm Academy of Sciences elected him a member in 1808, and in 1818 he became its perpetual secretary. The same year he was ennobled by Charles XIV, who in 1835 further made him a baron. He died at Stockholm on Aug. 7, 1848. During the first few years of his scientific career Berzelius was mainly engaged on questions of physiological chemistry, but about 1807 he began to devote himself to the elucidation of the composition of chemical compounds through study of the law of multiple proportions and the atomic theory. Perceiving the exact determination of atomic and molecular weights to be of fundamental importance, he spent ten years in ascertaining that constant for some two thousand simple and compound bodies, and the results he published in 1818 attained a remarkable standard of accuracy, which was still further improved in a second table that appeared in 1826. He used oxygen—in his view the pivot round which the whole of chemistry revolves—as the basis of reference for the atomic weights of other substances, and the data on which he chiefly relied were the proportions of oxygen in oxygen compounds, the doctrines of isomorphism, and Gay Lussac's law of volumes. When Volta's discovery of the electric cell became known, Berzelius, with W. Hisinger (1766–1852), began experiments on the electrolysis of salt solutions, ammonia, sulphuric acid, etc., and later this work led him to his electrochemical theory, a full exposition of which he gave in his memoir on the *Theory of Chemical Proportions and the Chemical Action of Electricity* (1814). This theory was founded on the supposition that the atoms of the elements are electrically polarized, the positive charge predominating in some and the negative in others, and from it followed his dualistic hypothesis, according to which compounds are made up of two electrically different components. At first this hypothesis was confined to inorganic chemistry, but later on he extended it to organic compounds, which he saw might similarly be regarded as containing a group or groups of atoms—a compound radicle—in place of simple elements. Although his conception of the nature of compound radicles did not long retain general favour—indeed, he himself changed it more than once—he is entitled to rank as one of the chief founders of the radicle theory. He continued and extended the efforts of Lavoisier and his associates to establish a convenient system of chemical nomenclature. By using the initial letters of the Latin (occasionally Greek) names of the elements as symbols for them, and adding a small numeral subscript, to show the number of atoms of each present in a compound, he introduced the present system of chemical formulation (see CHEMISTRY). He effected improvements in analytical methods and the technique of the blowpipe (*Über die Anwendung des Löthrohrs*, 1820), of his classification of minerals on a chemical basis, and of many individual researches such as those on tellurium, selenium, silicon, thorium, titanium, zirconium and molybdenum, most of which he isolated for the first time. Apart from his original memoirs, of which he published over 250, mostly in Swedish in the *Transactions* of the Stockholm academy, he published a *Lehrbuch der Chemie*, which went through five editions (first 1803–18, fifth 1843–48), and *Jahresbericht* (1821–48), or annual report on the progress of physics and chemistry, prepared at the instance of the Stockholm academy.

BERZEVICZY, ALBERT DE (1853–), Hungarian politician and writer. After studying law and politics at Budapest university, he travelled extensively in Europe. He was professor of law in the University of Eperjes and in 1881 was returned to the Hungarian parliament by the same town. He became minister

of education in 1903; from 1910–12 he was president of the House of Deputies. Berzeviczy published numerous historical and other works, among which may be mentioned *Absolutism in Hungary*, vol. I., (1925); *Landscape Painting in the 17th Century* (1910). In 1905 he was president of the Hungarian Academy of Sciences, over whose centenary celebrations he presided in 1925.

BES, the Egyptian god of recreation, represented as a dwarf with large head, goggle eyes, protruding tongue, shaggy beard, a bushy tail seen between his bow legs hanging down behind (sometimes clearly as part of a skin girdle) and usually a large crown of feathers on his head. A Bes-like mask was found by Petrie amongst remains of the twelfth dynasty. In the temple of the queen Hatshepsut at Deir el Bahri (c. 1500 B.C.), he is figured along with the hippopotamus goddess as present at the queen's birth. His figure is that of a grotesque mountebank, intended to inspire joy or drive away pain and sorrow, his hideousness being perhaps supposed actually to scare away the evil spirits. In his joyous aspect Bes plays the harp or flute, dances, etc. He is figured on mirrors, ointment vases and other articles of the toilet. Amulets and ornaments in the form of the figure or mask of Bes are common after the New Kingdom; he is often associated with children and with child-birth and is figured in the "birth-houses" devoted to the cult of the child-god. Perhaps the earliest known instance of his prominent appearance of large size in the sculptures of the temples is under Taharka, at Jebel Barkal, Nubia, at the beginning of the 7th century B.C. As the protector of children and others he is the enemy of noxious beasts, such as lions, crocodiles, serpents and scorpions. Large wooden figures of Bes are generally found to contain the remains of a human foetus. In the first centuries of our era an oracle of Besas was consulted at Abydos, and prescriptions exist for consulting Besas in dreams. Bes may be of non-Egyptian origin, African, as Wiedemann, or Arabian or even Babylonian, as W. Max Müller contends; the god is often named "coming from the Divine Land" (i.e., the East or Arabia), or "Lord of Puoni" (Punt), i.e., the African coast of the Red Sea; his effigy occurs also on Greek coins of Arabia. Contrary to the usual rule, he is commonly represented in Egyptian sculptures and paintings full faced instead of in profile.

BESANÇON, city of eastern France, capital of the department of Doubs, 76m. E. of Dijon by the P.L.M. railway. Pop. (1926) 44,415. It lies enclosed by hills on the river Doubs, under the western Jura. The Doubs almost surrounds the city proper, forming a peninsula, the high neck of which is crowned by the citadel; on the right bank lie populous industrial suburbs, including the frequented thermal and saline spa of Besançon-la-Mouillère. The limestone plateau of the Jura, with its open stretches and salt springs, was a centre of population in the Hallstatt Period (Early Iron Age), and the strategic site was soon recognized. As *Vesontio* it was the chief town of the Sequani, and in 58 B.C. was occupied by Julius Caesar. Marcus Aurelius promoted it to the rank of a *colonia*. During succeeding centuries it was several times destroyed and rebuilt. The archbishopric dates from the close of the 2nd century, and the archbishops gradually acquired considerable temporal power. In 1184 Frederick Barbarossa made it a free imperial city. It afterwards became detached from the German kingdom, and during the 14th century fell to the dukes of Burgundy, from whom it passed to the emperor Maximilian I. Under the Austro-Spanish domination (1477–1647) it became very prosperous, and superseded Dôle as the real capital of Franche-Comté. During the 17th century it was attacked several times by the French, to whom it was definitely ceded by the peace of Nijmegen in 1678. It was then fortified by Vauban. Until 1789 it was the seat of a *parlement*. In 1814 it was invested and bombarded by the Austrians, and was an important position during the Franco-German War of 1870–71.

The river is bordered by fine quays and by the shady promenades which are a feature of Besançon. The cathedral of St. Jean, founded in the 4th century, has often undergone reconstruction; it resembles the churches of the Rhine basin and also the cathedral of Nevers in having apses at both ends. The main portions date from the 11th, 12th and 13th centuries; the eastern apses and the tower are 18th century work. In the interior there are

a "Madonna and Child" of Fra Bartolommeo and a number of other mediaeval and modern works of art. The Archbishop's palace adjoining the cathedral is 18th century. The Palais Granvelle, in the heart of the town, was built from 1534 to 1540 by Nicolas Perrenot de Granvelle, chancellor of Charles V. Built round an arcaded courtyard, it is occupied by the learned societies of the town. The hôtel de ville, like much of the town, dates from the 16th century. The law court preserves a Renaissance façade and a fine 18th century audience hall. A 15th century round tower and the 16th century Porte Rivotte are relics of fortifications. The Roman remains include a triumphal arch (the Porte Noire, partly rebuilt in 1820) decorated with bas-reliefs, considered to have been built in commemoration of the victories of Marcus Aurelius in 167; remains of a theatre, or an amphitheatre, of an aqueduct, and of a former Roman bridge, forming part of the modern bridge. Besançon has statues of Victor Hugo (b. 1802), and of the Marquis de Jouffroy d'Abbans (b. 1751), inventor of steam navigation.

It is the seat of an archbishopric, a court of appeal and a court of assize, centre of an *académie* (educational division), seat of a prefect and headquarters of the VII. army corps. It has tribunals of first instance and of commerce, a chamber of commerce, a board of trade-arbitrators and an exchange. The university (founded in 1287) has faculties of science and letters, a preparatory school of medicine and pharmacy and a free faculty of law. The library contains over 130,000 volumes, and the city has good collections of pictures, antiquities and natural history. The chief industry of Besançon is watch- and clock-making, introduced from the district of Neuchâtel in the 18th century. The artificial silk industry is also important, the wood pulp from the Jura forests being a factor in the early location of the industry here.

BESANT, ANNIE (1847–), British theosophist, was born in London, Oct. 1, 1847, the daughter of William Page Wood. She married, in 1867, the Rev. Frank Besant (d. 1917), afterwards vicar of Sibsey, Lincs., but obtained a separation from her husband in 1873. She had become an ardent Freethinker, and from 1874 to 1888 she worked in close association with Charles Bradlaugh, both in politics and in freethought propaganda, as a lecturer and a writer of pamphlets over the signature of "Ajax." Her increasing tendency towards Socialism of the more revolutionary type occasioned a divergence between them after 1885, which was completed in 1889 by her adhesion to the Theosophical Society. She became a devoted pupil of Mme. Blavatsky, and threw in her lot very largely with India. She founded the Central Hindu college at Benares, and was elected president of the Theosophical Society in 1907; she established the Indian Home Rule League and became its president in 1916, and in 1917 she was president of the Indian National Congress, but later dissociated herself from the extreme wing of the Nationalist Party. For a short time in 1917 she was interned at a hill station by Lord Pentland. While the Montague reforms were in preparation Mrs. Besant at first supported the Government, but, after a brief spell of constitutionalism, she again advocated with astounding energy the extreme nationalist position. Meanwhile the strange episode of her protégé, J. Krishnamurti, who was to be the new world teacher, had begun in 1910, and the new Order of the Star was founded. In 1926–27 Mrs. Besant travelled widely in England and America with Krishnamurti, as the new Messiah, urging his claims much more vehemently than he wished. Returning to India she was involved in a lawsuit with the father of the boy, and she withdrew much of what she had said. Her gifts of oratory and organization had carried her to the position, unique for an Englishwoman, of leader in a Hindu political movement. In addition to her numerous freethought pamphlets and works on theosophy, she published an *Autobiography* (1893), and *The Religious Problem in India* (1902).

BESANT, SIR WALTER (1836–1901), English author, was born at Portsmouth on Aug. 14 1836. He was educated at King's college, London, and Christ's college, Cambridge, graduated in 1859 as 18th wrangler, and from 1861 to 1867 was senior professor of the Royal college, Mauritius. From 1868 to 1885 he

acted as secretary to the Palestine Exploration Fund. In 1884 he was mainly instrumental in establishing the Society of Authors, a trade-union of writers designed for the protection of literary property, which has rendered great assistance to inexperienced authors by explaining the principles of literary profit. Of this society he was chairman from its foundation in 1884 till 1892. He married Mary, daughter of Mr. Eustace Foster-Barham, of Bridgwater, and was knighted in 1895. He died at Hampstead on June 9 1901. Besant's first stories were written in collaboration with James Rice. Two at least of these, *The Golden Butterfly* (1871), and *Ready-Money Mortiboy* (1872), are among the most vigorous and most characteristic of his works. After Rice's death Sir Walter wrote *All Sorts and Conditions of Men* (1882), a stirring story of East End life in London, which set on foot the movement for the establishment of the People's Palace in the Mile End road. His sympathy with the poor was also shown in another attempt to stir public opinion, this time against the evils of the sweating system, in *The Children of Gibeon* (1886).

Other popular novels by him were *Dorothy Forster* (1884), *Armored of Lyonesse* (1890), and *Beyond the Dreams of Avarice* (1895). He also wrote critical and biographical works, including *The French Humorists* (1873), *Rabelais* (1879); and lives of Coligny, Whittington, Captain Cook and Richard Jefferies. Besant undertook a series of important historical and archaeological volumes, dealing with the associations and development of the various districts of London, of which the most important was *A Survey of London*, unfortunately left unfinished, which was intended to do for modern London what Stow did for the Elizabethan city. Other books on *London* (1892), *Westminster* (1895) and *South London* (1899) showed that his mind was full of his subject. The improved conditions of the literary career in England are largely due to his efforts.

BIBLIOGRAPHY.—See also *Autobiography of Sir Walter Besant* (1902), with a prefatory note by S. S. Sprigge; the preface to the library edition (1887) of *Ready-Money Mortiboy* contains a history of the literary partnership of Besant and Rice.

BESELER, HANS VON (1850–1921), Prussian general and governor of Poland during the German occupation, was born on April 27, 1850, at Greifswald, and entered the army. He was on the retired list at the outbreak of the World War, but was recalled. He conducted the siege of Antwerp, which he occupied on Oct. 9, 1914. In 1915, he was employed on the eastern front, where he took Novogeorgievsk on Aug. 19. From Aug. 27, 1915, to Nov. 1918 he was German governor-general of Poland at Warsaw. He endeavoured, with diminishing success, to organize a form of Polish national government and representation under German auspices and to form a Polish army under German control, until the Armistice put an end to his schemes. He died near Potsdam on Dec. 22, 1921.

BESINVAL DE BRONSTATT, PIERRE VICTOR, BARON DE (1722–1791), French soldier, was born at Soleure. He became commander of the Swiss Guards in succession to his father. When the Revolution began Besenval was given command of the troops which the king had concentrated on Paris in July 1789—a movement which led to the taking of the Bastille on July 14. Besenval was inactive in the crisis, was arrested, tried by the tribunal of the Châtelet, but acquitted. He died in Paris on June 3, 1791. The authenticity of the rather scandalous *Mémoires* (ed. T. A. de Ségur, 4 vols. 1805–07) attributed to him is disputed.

BESKOW, BERNHARD VON, BARON (1796–1868), Swedish dramatist and historian, son of a Stockholm merchant, was born on April 19, 1796. He held high appointments at court and was, from 1834 onwards, perpetual secretary of the Swedish academy, using his great influence with tact and generosity. His poetry is over-decorated, and his plays are grandiose historical poems in dramatic form. Among them are "Erik XIV.," 2 parts (1826); and four pieces collected (1836–38) as *Dramatiska Studier*, the most famous of which is the tragedy of "Thorkel Knutsson." His works include many academical memoirs, volumes of poems, philosophy, and a valuable historical study, *Om Gustav den Tredje såsom konung och människa* (5 vols. 1860–69, "Gustavus III. as king and man"), printed in the transactions of the

Swedish academy (vols 32, 34, 37, 42, 44). He died on Oct. 17, 1868.

See also a notice by C. D. af Wirsén in his *Lefnadsteckningar* (Stockholm, 1901).

BESNARD, PAUL ALBERT (1849–), French painter, born in Paris on June 2, 1849, studied at the École des Beaux-Arts, winning the Prix de Rome in 1874. He was a pupil of J. Brémont and of Cabanel. He lived in England from 1879 to 1883, and was a friend of Legros, from whom he learned the art of etching. He devoted himself to the study of colour and light as conceived by the impressionists, and he applied their new vision of light and atmosphere to ideological and decorative works on a large scale, such as his frescoes at the Sorbonne, the École de Pharmacie, the Salle des Sciences at the Hôtel de Ville, the mairie of the first arrondissement, the Musée des Arts Decoratifs, the Comédie Française, and the chapel of Berck hospital, for which he painted 12 "Stations of the Cross." He travelled to Algiers, Morocco and India, bringing back sketches sparkling with light and colour. From 1913 to 1919 he was director of the Académie de France in Rome, and on his return became director of the École Nationale des Beaux-Arts, and president of the Salon des Tuileries, which he helped to found in 1923. A great virtuoso, he achieved brilliant successes alike in water-colour, pastel, oil and etching; also in portraiture, in landscape and in decoration. A good example of his work is his portrait of Mme. Réjane; and his analysis of light can be studied in his picture "Femme qui se chauffe" at the Luxembourg in Paris.

BESOM, a bundle of rods or twigs (Old Eng. *besema*, a rod) used for sweeping; a stiff broom.

BESSARABIA, a province of Rumania extending from Poland on the north, about lat 48° 3' N., to the Black sea, and lying between the Pruth and Dniester rivers. The latter divides it from the Ukrainian and Moldavian autonomous republics of the Russian federation, while the former separates it from the Rumanian province of Moldavia. After the Russian revolution of Oct. 1917, the National Council of Bessarabia declared a Moldavian Democratic Republic, forming part of the R S F S R, but later Bessarabia first declared herself entirely independent and in Nov. 1918, agreed to unconditional incorporation with Rumania. The Treaty of Paris Oct. 28, 1920 signed by the British empire, France, Italy and Japan recognized this incorporation, but the United States of America stood aside from the treaty on the ground that there was no representative of the Russian government to state the Russian side of the case. Russia still regards Bessarabia as "occupied territory," and no settlement was reached between the Russian and Rumanian delegates when they met in Genoa in 1922 and in Vienna in 1924. Thus at present (1928) the province is in a state of military occupation, with Soviet pickets on the left bank of the Dniester, and Rumanian pickets on the right, Kishinev being the headquarters of the Rumanian military. The situation is disastrous to the commerce of both countries, but is particularly so for the province of Bessarabia, since the Dniester was formerly the main artery for Bessarabian grain and wool. Three Bessarabian railways were arranged to converge on Odessa, while the fourth linked with Akkerman (Cetatea Alba) and thence by sea with Odessa. The latter town formed the natural outlet for Bessarabian cereals, fruit and wine, which found a ready market in Russia, but which are less easily disposed of to agricultural Rumania.

Bessarabia consists of (1) the black-earth agricultural region of the Volhynian-Podolian plateau (850 to 1,150 ft.) in the north (2) the central area, deeply dissected by north-west to south-east tributaries of the Dniester, and shorter north-east to south-west tributaries of the Pruth. The soil is mainly *podzol*, with marshy soils in the valleys especially that of the Reut; this region is thickly forested with beech, oak and mountain ash, and with birch in places. (3) the Budjak steppe area, south of the line of old Roman earthworks which extend from Leovo, the limit of

navigation on the Pruth river, almost to the junction of the Botna river with the Dniester river. The steppe merges into the sandy soils, saltmarshes and lagoons of the coastal area. The climate is extreme, with a rainfall of about 25 in. per annum. The average January temperature at Kishinev is 27° F, July 72° F.

Agriculture is the main occupation, with maize and wheat as the chief grain crops. Fruit growing is widespread, the Bessarabian plum being particularly fine. Except in the north, vineyards are widespread, though the local wine is sour and liable to go bad during transport. Tobacco, barley, flax, watermelons, saffron and madder are grown. In the steppe pasture-lands sheep, cattle, horses, goats, pigs and buffaloes are reared, though their numbers have greatly diminished since 1915, when there were nearly 3,000,000 head in the country. Wool and woollen cloth are exported, and there are small manufactures of leather, soap and iron goods. Fishing is productive near the Shabalat and Dniester limans. Marble is quarried and salt and saltpetre worked.

The economic life of Bessarabia has been much disturbed by the 1914-1921 war conditions, and by the continued severance of trade relations with Russia. Administrative changes have meant radical alterations in the life of the people; new currency has had to be adopted; the old *zemstvos* and *volosts* (district and sub-district councils) have been replaced by prefects and sub-prefects appointed from Bucharest; there has been expropriation of all private estates over 100 hectares in extent. Communications, formerly poor, are still worse now, partly because the railways are of a different gauge from those in the rest of Rumania and partly because they do not link with Rumanian ports. In addition the Dniester is no longer available for trade.

The area of Bessarabia is 44,420 sq km and its population in 1922 was 2,957,000. Of these Moldavians form about 50%, and Ukrainians about 20%, and there are also Jews, Russians, Bulgarians and Germans; colonies of the latter settled in the Budjak steppe to the west of Akkerman in 1814. Nomad gypsies (*tsigane*) also inhabit the steppe. The chief towns are Kishinev (Chisinau), the capital, on the Byk river, Hotin, Bender and Akerman (Cetatea Alba) three river ports on the Dniester; Ismail (Tuchkoff), Reni and Kagul, river ports on the Pruth. Balti (Byeltsi) on the Reut, is also of some importance.

The original inhabitants were Cimmerians, and after them came Scythians. In early Christian times Bessarabia, a key to the Byzantine empire, was often invaded. In the 2nd century it was occupied by the Getae, a Thracian tribe, whom the Roman emperor Trajan conquered in 106; he then incorporated the region in the province of Dacia. In the following century the Goths poured into this quarter of the empire, and in the 5th century it was overrun by Huns, Avars and Bulgarians. Then followed in the 7th century the Bessi, a Thracian tribe, who gave their name to the region, and in the 9th the Ugrians, the ancestors of the present Magyars, the country being then known as Atel-kuzu. The Ugrians were forced farther west by the Turkish tribe of the Petchenegs in the 10th century, and these were succeeded in the 11th century by the Kumans (Comani) or Polovtsians, a kindred Turkish stock or federation. In the 13th century Bessarabia was overrun by Mongols under the leadership of Batu, grandson of Jenghiz Khan. In this century also the Genoese founded trading factories on the banks of the Dniester. In 1367 Bessarabia was subdued and annexed by the ruling prince of Moldavia. During the 16th century it was in possession alternately of Turks and Nogais or Crimean Tatars. From early in the 18th century it was a bone of contention between Ottoman Turks and Russians, the latter capturing it five times between 1711 and 1812. In the latter year it was definitely annexed to Russia, and in 1829 its frontier was pushed southwards so as to include the delta of the Danube. After the Crimean War, however, Russia ceded to Moldavia not only this later addition, but also certain districts in the south of the existing government, amounting altogether to an area of 4,250 sq.m., and a pop. of 180,000. By the treaty of Berlin (1878) Russia recovered 3,580 sq.m., with pop. 127,000.

See *British White Paper Cmd. 1747 of 1922. The Rumanian occupation in Bessarabia. Documents.* Paris 1919; A. Babel, *La Bessarabie* (1927); O. G. Lecca, *Formation et Développement du Pays et des États Roumains* (1922).

(R. M. F.)

HISTORY

• The history of Bessarabia goes back to the early Christian era, when it was already a bulwark of Christian Europe against the barbarians. Traces of the walls erected by the Emperor Trajan to protect the old Roman colony of Dacia still exist in the southern extremity of the province. Later, fortified towns such as Hotin (Khotin), Soroca, Tighina (Bender) and Cetatea Albă (the Turkish Akerman) were built and maintained under alternating Rumanian princes and Turkish suzerains until, in 1812, Russia, in pursuance of the policy initiated by Catherine II. of extending Russian territory eastward at the expense of the Turkish empire, and to obtain command of the mouth of the Danube, annexed the province now known as Bessarabia and, under the Treaty of Bucharest, left the Turks in possession of that portion of the Principality of Moldavia to the west of the Pruth.

Annexation by Russia.—Although the annexation was styled by the Russians "the delivery of the Moldavians from the pagan yoke of Turkey" (see Casso's *Russia to the Danube*, Moscow, 1913) it is significant that, fearing the introduction of serfdom, an exodus of the peasantry commenced forthwith, only to be checked by drastic measures on the part of the Turks who, declaring the Russian portion of the province to be contaminated by the plague, put to the sword all who crossed the Pruth.

Thus, for over a century the province continued under Russian domination (except three southern districts restored to Rumania in 1856 after the Crimean War, which, however, were taken back by Russia in 1877 in exchange for the Dobrudja), becoming slowly Russianized and more or less satisfied with its lot. It must, however, be remembered that the Russian population in the province was small, consisting solely of landed proprietors and the officials and military required to administer and garrison the province. For the rest, the population consisted—as to-day—of compact masses of Moldavians and scattered colonies of Bulgars, Tartars, Ruthenians and Germans. The towns were populated with Jews, who by Russian edict were forced to live in the provinces and forbidden residence in the capital and larger towns of Russia.

Union with Rumania.—With the fall of the Imperial régime in 1917 and the establishment of the Soviet republics, the leading Bessarabians declared for autonomy, and a National Council (*Sfatul Tărei*) was formed. Fearing, however, that the wave of terrorism following the collapse of the Russian army in the field would swamp the province, appeal was made to Rumania for military assistance in guarding the railways and keeping order. This was forthcoming conditionally on eventual union with Rumania, and on Jan. 24, 1918, as an initial step to this end, the National Bessarabian Council declared the province to be the "Independent Moldavian Republic" and renounced all connection with the Soviet Union. On Nov. 27, 1918, "*Sfatul Tărei*" held its last session and decided that Bessarabia should, voluntarily and unconditionally, be united to Rumania. Elections took place in 1919 and Bessarabian representatives were sent for the first time to the central National Assembly at Bucharest.

The union of the province was not recognized by the Allied Powers until March 1920. On Oct. 28 of that year a treaty was executed and signed by England, France, Italy, Rumania and Japan, giving concrete form to this recognition. The treaty was soon ratified by France and England, and on March 14, 1927, by Italy; Japan still withholding final approval. The U.S.S.R. never acknowledged the union of Bessarabia with Rumania, maintaining the province to be an integral part of the old Imperial territory now under Soviet rule, and holding invalid the act of "*Sfatul Tărei*" in voting for union with Rumania. Rumania, however, asserted that the action of the Bessarabians who, simultaneously with the Estonians, Lettonians and Ukrainians, adopted the principle of self-determination, could in no way be described as a Bolshevik movement but as a Moldavian national one, and that their choice of union with Rumania should consequently be respected.

Administration.—With the passing of the Russian régime, the system of administration in the province also underwent change. The *zemstvos* (district councils) were abolished and prefects set up in their places. There are nine administrative districts

in the province, each in the charge of a prefect, whose powers are limited, and who is responsible to the central authority at Bucharest. A state of siege existed in the province after the Union and a strong garrison was maintained, especially along the Dniester.

Economics.—By Agrarian Reform (a measure which, dictated by the circumstances of the moment, Rumania claims to have saved the province from Bolshevism) land has been given to the peasants, who require increased facilities, however, for its fuller development. Money is limited and credit practically non-existent, so that the merchants, whose existence at least would be assured if the peasants' purchasing potentialities were greater, are often in difficult circumstances. The government is, however, alleviating the situation by the institution of popular banks, granting loans at low interest, and by other means. By the fall of the Imperial régime and the institution of Bolshevism in Russia, Bessarabia has unfortunately lost her pre-war markets for her wines, cereals, oil seed, etc. Rumania, itself an agricultural country, has little need of Bessarabian products; which would, in any case, prove difficult and costly to transport owing to the lack of railway communications between the province and the old kingdom.

Railways.—A big programme of railway construction was under consideration in 1928 and it was hoped to give effect, during the next four or five years, at least to the most vital part of the programme, which provides for increased links with Bessarabia and a re-orientation of existing lines towards Bucharest and the Danube ports, as well as connecting links with Transylvania through the Bukovina. With the diversion of the present lines from Moscow and Odessa, the necessary impetus will be given to Bessarabian trade.

BESSARION, JOHANNES or BASILIUS (c. 1395–1472), titular patriarch of Constantinople, and an illustrious Greek scholar who contributed to the revival of letters in the 15th century, was born at Trebizond, the year of his birth being variously given as 1380, 1395, or 1403. He was educated at Constantinople, and under Gemistus Pletho the Neo-Platonist (1423). On entering the order of St. Basil, he took the name of Bessarion. In 1437 he was made archbishop of Nicaea by John VII. Palaeologus, whom he accompanied to Italy in order to bring about a union between the Greek and Latin churches, with the object of obtaining help against the Turks. At the councils held in Ferrara and Florence Bessarion supported the Roman Church, and gained the favour of Pope Eugenius IV., who invested him with the rank of cardinal. From that time he resided in Italy, doing much, by his patronage of scholars, by his collection of books and manuscripts, and by his writing to spread abroad the new learning. In 1463 he received the title of Latin patriarch of Constantinople. For five years (1450–55) he was legate at Bologna, and he was engaged on embassies to foreign princes, among others to Louis XI of France in 1471. He died on Nov. 19, 1472, at Ravenna. Bessarion was one of the most learned scholars of his time. Besides his translations of Aristotle's *Metaphysics* and Xenophon's *Memorabilia*, his most important work is a treatise against George of Trebizond, a violent Aristotelian, entitled *In Calumniatorem Platonis*. Bessarion rather strives after a reconciliation of the two philosophies. His work, by opening up the relations of Platonism to religion, contributed to the extension of speculative thought in theology. His library, which contained a large collection of Greek mss. was presented by him to the senate of Venice, and formed the nucleus of the library of St. Mark.

Mohler, *Kardinal Bessarion* (Paderborn, 1923); Von Bessarion at the councils of Ferrara and Florence, A. Sadow, *Bessarion de Nicée* (1883); on his philosophy, monograph by A. Kandelos (in Greek: Athens, 1888). Most of his works are in Migne, *Patrologia Graeca*, clxi.

BESSEL, FRIEDRICH WILHELM (1784–1846), German astronomer, was born at Minden July 22, 1784. In 1804 he calculated the orbit of Halley's comet from observations made in 1607 by Thomas Harriot, and communicated his results to H. W. M. Olbers, who procured their publication (*Monatliche Correspondenz*, x. 425), and recommended him in 1805 for the post of assistant in J. H. Schröter's observatory at Lilienthal. A masterly investigation of the comet of 1807 (Königsberg, 1810) led the king of Prussia to summon him, in 1810, to superintend the erection of a new observatory at Königsberg, of which he acted as director from its completion in 1813 until his death. In this capacity he inaugurated the modern era of practical astronomy. For the purpose of improving knowledge of star-places he reduced James Bradley's Greenwich observations, and derived from them an invaluable catalogue of 3,222 stars, published in the volume named *Fundamenta Astronomiae* (1818). In *Tabulae Regiomontanae* (1830) he definitely established the uniform system of reduction still in use. During the years 1821–33 he observed all stars to the ninth magnitude in zones extending from -15° to $+45^{\circ}$ dec., and thus raised the number of those accurately determined to about 50,000. He corrected the length of the seconds' pendulum in 1826, in a discussion re-published by H. Bruns in 1889; measured an arc of the meridian in East Prussia in 1831–32, and deduced for the earth in 1841 an ellipticity of $\frac{1}{231.5}$. His ascertainment in 1838 (*Astronomische Nachrichten*, Nos. 365–366) of a parallax of $0''.31$ for 61 Cygni was the first authentic result of the kind published. He announced in 1844 the binary character of Sirius and Procyon from their disturbed proper motions; and was preparing to attack the problem solved later by the discovery of Neptune, when he died at Königsberg March 17, 1846. Modern astronomy of precision is essentially Bessel's creation. Apart from the large scope of his activity, he introduced the effective use of the heliometer, the correction for personal equation (in 1823), and the systematic investigation of instrumental errors. He issued 21 volumes of *Astronomische Beobachtungen auf der Sternwarte zu Königsberg* (1815–44), and a list of his writings drawn up by A. L. Busch appeared in vol. 24 of the same series. Especial attention should be directed to his *Astronomische Untersuchungen* (1841–42), *Populäre Vorlesungen* (1848), edited by H. C. Schumacher, and to the important collection entitled *Abhandlungen* (1875–82), issued by R. Engelmann at Leipzig. His minor treatises numbered over 350. In pure mathematics he enlarged the resources of analysis by the invention of Bessel's Functions. He made some preliminary use of these expressions in 1817, in a paper on Kepler's Problem (*Transactions Berlin Academy*, 1816–1817, p. 49), and fully developed them seven years later, for the purposes of a research into planetary perturbations (*ibid.* 1824, pp. 1–52).

Society*, vii. 109 (1847); *Allgemeine deutsche Biographie*, ii. 558–567.

BESSEL FUNCTION, in mathematics, a solution of Bessel's differential equation

$$x^2 \frac{d^2 y}{dx^2} + x \frac{dy}{dx} + (x^2 - n^2)y = 0.$$

The designation *cylinder function*, also used by many writers, has its source in the use of these functions to express solutions of such physical problems as the flow of heat or of electricity in a solid circular cylinder. They first appear in this connection in the work of J. B. J. Fourier (*La Théorie analytique de la Chaleur*, 1822, and a memoir of 1811, published in 1824). They had, however, been previously employed in other physical and astronomical problems. In 1732 Daniel Bernoulli investigated the transverse oscillations of a heavy chain suspended at one end, and expressed the horizontal displacement in terms of a Bessel function. Leonhard Euler found, in 1764, that these functions could be used to evaluate the displacement of a point on a vibrating stretched membrane. Their first use in celestial mechanics is in Lagrange's memoir of 1770 on Kepler's Problem concerning the motion of a planet about the sun. They were also employed by other writers

of the earlier classical period of mathematics (Poisson, 1823, Laplace, *Mécanique Céleste*, 1827). F. W. Bessel, after whom these functions are named, made a systematic investigation of their properties in his memoir of 1824 on Kepler's Problem, following his earlier paper of 1817 on the same subject.

The importance of Bessel functions in mathematical physics and astronomy is indicated by the foregoing examples of their applications, to which we may add more modern solutions of problems in wave-theory, elasticity, hydrodynamics, and optics. The bibliography of G. N. Watson (*A Treatise on the Theory of Bessel Functions*, Cambridge University Press, 1922) contains a list of over seven hundred papers on these functions and their applications.

In modern treatises Bessel functions are considered as depending both upon x and n , which may have complex as well as real values. The value of n is called the *order* of the function. Three kinds are distinguished. The *Bessel function of the first kind*, designated by $J_n(x)$, is given by the infinite series

$$\frac{x^n}{2^n \Gamma(n+1)} \left[1 - \frac{x^2}{2 \cdot (2n+2)} + \frac{x^4}{2 \cdot 4 \cdot (2n+2)(2n+4)} - \dots \right],$$

where $\Gamma(n+1)$ is the gamma function, which is equal to the product of all integers from 1 to n when n is a positive integer. Functions of the *second kind*, designated by $Y_n(x)$ and $K_n(x)$, are variously defined, but are expressible as linear combinations of functions $J_n(x)$ and $J_{-n}(x)$, or limits of such combinations, while functions of the third kind, $H_n(x)$, are of the form $J_n(x) \pm \sqrt{-1} Y_n(x)$.

These functions are expressible as limiting cases of spherical harmonics. They also appear as coefficients in series expansions of certain elementary functions. Extensive studies have been made of the problem of expressing an arbitrary function in terms of infinite series or of definite integrals in terms of Bessel functions. In this connection it has been necessary to determine the zeros of Bessel functions. Asymptotic expansions have also furnished an extensive field of investigation.

Many tables of these functions have been published. Among the best and most extensive are those of Watson in the work already quoted.

Mathews, *A Treatise on Bessel's Functions* (1895); N. Nielsen, *Handbuch der Theorie der Cylinderfunktionen* (Leipzig, 1904). (R. D. C.)

BESSEMER, SIR HENRY (1813–1898), English engineer, was born on Jan. 19, 1813, at Charlton, in Hertfordshire. Throughout his life he was a prolific inventor, but his name is chiefly known in connection with the Bessemer process for the manufacture of steel. It has been of enormous industrial importance, since it effected a great cheapening in the price of steel. Bessemer's attention was drawn to the problem of steel manufacture in the course of an attempt to improve the construction of guns. His process was the decarbonization of cast iron by forcing a blast of air through the mass of metal when in the molten condition. Thus he was able to convert melted cast iron into malleable iron in a perfectly fluid state. The first public announcement of the process was made at the Cheltenham meeting of the British Association in 1856. He erected steelworks in Sheffield to develop the process. At the outset he had found great difficulty in making steel by his process—in his first licenses to the trade iron alone was mentioned. Experiments he made with South Wales iron were failures because the product was devoid of malleability. Robert Mushet showed that the addition of a certain quantity of spiegeleisen (see IRON AND STEEL) had the effect of removing the difficulties. The value of Mushet's procedure was shown by its general adoption in conjunction with the Bessemer method of conversion but Bessemer proved it not essential by showing, in 1865, samples of steel made by his own process. Bessemer became F.R.S., and received a knighthood in 1879. He died at Denmark hill, London, on March 15, 1898.

See an *Autobiography* with concluding chapter by Sir Henry's son, H. Bessemer (1924); R. F. Mushet, *The Bessemer-Mushet process* (1883).

BESSEMER, a city of Jefferson county, Ala., U.S.A., 11m. S.W. of Birmingham, in the centre of the iron, coal and limestone region of the State. It is served by the Atlanta, Birmingham and Atlantic, the Birmingham Southern, the Frisco, the Illinois Central, the Louisville and Nashville, the Seaboard Air Line, and the Southern railways. The population in 1920 was 18,674, of whom considerably more than half (10,561) were negroes; and after annexation of new territory in 1927 was estimated at 40,000. It is a part of the Birmingham workshop and has immense iron and steel industries and coal-mining operations, and also manufactures fertilizers, brick, coal-tar derivatives and high explosives. There are about 12,000 persons on the industrial pay-roll of \$15,000,000. Bessemer was laid out in 1887, incorporated in 1888, and had a population of 4,544 at the 1890 census. It was named after Sir Henry Bessemer.

BESSEMER, a city near the north-west corner of the upper peninsula of Michigan, U.S.A., about 15m. from Lake Superior; the county-seat of Gogebic county, and the centre of important mining and lumbering operations. There are 12 iron mines in the immediate vicinity. It is on Federal highway 2, and is served by the Chicago and North Western, the Duluth, South Shore and Atlantic, and the Soo railroads. The population in 1920 was 5,482, of whom 2,084 were foreign-born whites.

BESSEMER STEEL. In 1856, in a paper before the British Association, Bessemer outlined the method associated with his name which, with modifications in detail, gave to the world the power to make steel cheaply. After several revisions in the design of the blowing vessel, the present shape was determined as the most satisfactory and a works was established in

Sheffield in 1860 to operate the process. Almost concurrent with Bessemer's experiments trials on similar lines were being made by William Kelly in the United States. Kelly's efforts were never carried to a commercial stage, although he was adjudged to have certain rights under the American patent laws. A settlement was made, however, between Bessemer and Kelly under which the latter retired and the claims of the English inventor were in future unchallenged. The application of the process spread rapidly both in Great Britain and abroad, but the later development of the Open Hearth method of steel manufacture checked the growth of the Bessemer process. Whilst the output of Bessemer steel especially on the Continent, for reasons which will be indicated later, is still very large, the quantity tends to decline in relation to the amount made in Open Hearth furnaces.

Theory of Process.—Pig-iron contains a number of constituents in addition to iron. These include carbon, silicon, sulphur, phosphorus and manganese. Steel contains similar constituents, but in different proportions. Steel making therefore consists in eliminating, or adding, the necessary constituents to pig-iron under conditions which enable the ultimate result to be controlled with certainty. This is an important point since the character of steel alters quickly with a relatively small difference in its constituents.

All the elements named, including iron, have a strong affinity for oxygen with the exception of sulphur and phosphorus, which are not affected by it. Further, the reactions of iron, carbon,

FIG. 1.—POSITIONS IN THE OPERATION OF A BESSEMER CONVERTER

FIG. 2

silicon and manganese with oxygen are each heat producing. The essential principle of the Bessemer process consists of blowing air under pressure through a body of molten pig-iron thus oxidizing rapidly by atmospheric oxygen a portion of the iron, practically all the silicon and manganese and, finally, the carbon. The heat generated is sufficient to maintain the metal in a liquid state.

At the end of the blow the vessel contains liquid metal consisting of iron, sulphur and phosphorus covered with a layer of slag. In order to convert the metal into steel the requisite amounts of manganese, silicon and carbon have to be added. This is done by using ferro-manganese, ferro-silicon or anthracite coal. These additions also act as deoxidizers and serve to remove any excess oxygen present in the metal after blowing.

As already indicated, sulphur and phosphorus are not affected by the process as described, and Bessemer was compelled to use pig-iron as free of these elements as possible. A large proportion of the pig-iron made, however, contains more phosphorus than is permissible in steel, and this iron was useless until Thomas

and Gilchrist conceived the idea of lining the vessel with basic material, such as magnesian limestone, and adding lime to the metal while blowing. A reaction takes place between the phosphorus and the lime, forming calcium phosphate, which again makes a slag on the metal. The discovery of this Basic Bessemer process in 1878 was of the utmost importance, as it made possible the utilization of the vast resources of phosphoric iron ore in Lorraine and in America.

Description of Plant.—The principal component of a Bessemer plant is naturally the vessel or converter. This is illustrated in fig. 2 which shows a pear-shaped vessel of steel lined with a suitable refractory material, siliceous in the case of the Acid Bessemer and dolomite in the Basic Bessemer. The capacity of the vessel varies with the conditions of the plant, many of those in Great Britain being capable of holding 10 tons, whilst in the U.S.A. vessels of 25 tons capacity are frequently used. The bottom of the vessel is made easily removable, a development introduced by Holley in America. In the bottom are carried the

FIG. 3.—DIAGRAMMATICAL PLAN SHOWING ARRANGEMENT OF A BESSEMER STEEL PLANT

tuyere blocks in which are formed the holes for the introduction of the pressure air to the liquid metal.

The vessel is carried on substantial trunnions, and is capable of being rotated through an angle of about 200° by hydraulic cylinders operated through controlling valves arranged on a platform located at a safe distance. The pig-iron in some cases is brought cold to the plant and melted in a cupola, but in more modern practice the iron is carried in ladles, whilst still liquid, from the blast furnace and poured into a large cylindrical vessel known as a metal mixer. The mixer in some works has a capacity of 1,000 tons of metal, and therefore with such a large store any variation in the quality of the pig-iron is rectified by mixing.

The three positions shown in fig. 1 indicate how the converter is held whilst filling, blowing and pouring respectively. As the converter is rotated from the filling to the blowing position the liquid metal flows over the tuyeres, but as air at a pressure of 25 lb. per sq. in. is being blown through them this prevents any choking. The action during blowing is vigorous. A shower of sparks is ejected continuously, and after a few moments a yellowish red flame appears which persists for four or five minutes. The temperature of the metal rises and boiling commences. The flame increases in size and becomes bright, intense, and of characteristic colour. After about eight minutes the flame changes to a bluish colour, becomes almost transparent and "drops," showing that the reactions are over. The blow occupies about 20 mins. in all. The converter is now turned horizontal and the ferro-manganese added. The steel is then ready and is poured into a ladle from which it is tapped into ingot moulds.

Thus a charge of pig-iron of a weight in some cases up to 25 tons can be converted into steel in about 25 mins. The vessel is turned with spout downwards and completely emptied; any repairs are then done to the lining and a new charge is at once introduced. A diagrammatic arrangement of a Bessemer plant is shown in

figure 3, above.

A typical example of the changes which take place during the blowing of an acid Bessemer charge is as follows.—

Constituents.	Pig-iron.	End of first stage 4 mins.	After 9 mins. blow.	End of blow	Steel ingot.
Graphite carbon	2.030				
Combined carbon	1.240	2.270	1.580	0.097	0.466
Silicon	1.052	0.790	0.635	0.020	0.030
Sulphur	0.014	trace	trace	trace	trace
Phosphorus	0.048	0.051	0.064	0.067	0.055
Manganese	0.086	trace	trace	trace	0.870

BESSEY, CHARLES EDWIN (1845–1915), American botanist, was born at Milton, O., on May 21, 1845. He graduated at Michigan Agricultural college (1869), and studied with Dr. Asa Gray at Harvard (1872–73 and 1875–76). At Iowa Agricultural college he was professor of botany (1870–84), and was acting president in 1882; at the University of Nebraska, professor of botany after 1884, acting chancellor (1888–89, 1899–1900 and 1907), and head dean after 1909. He was one of the ablest investigators and teachers of botany of his time and a pioneer in introducing present laboratory methods of teaching biology. With the publication of *Botany for High Schools and Colleges* (1880), he introduced morphology to America. This book was the first in the series of "Bessey's text-books," which set a standard for modern work. The development of various interests of the State of Nebraska was the result of his generous public interest. He was a member of many national organizations, and was elected to

almost every office to which an American botanist could aspire, culminating in the presidency of the American Association for the Advancement of Science.

He was the author of *Geography of Iowa* (1876); *Botany for High Schools and Colleges* (1880); *Essentials of Botany* (1884); *Elementary Botanical Exercises* (1892); *Phylogeny and Taxonomy of Angiosperms* (1897); *Elementary Botany* (1904); *Plant Migration Studies* (1905); *Synopsis of Plant Phyla* (1907); *Phyletic Idea in Taxonomy* (1908); and *Outlines of Plant Phyla* (1909-11-12-13). He was botanical editor of *The American Naturalist* (1880-97), of *Science* from 1897, and of *Johnson's Cyclopaedia* from 1893 until his death in 1915.

For further biography see John M. Coulter's "Charles Edwin Bessey," *Science*, new series, vol. xli.

BESSIÈRES, JEAN BAPTISTE, duke of Istria (1768-1813), French marshal, served for a short time in the "Constitutional Guard" of Louis XVI. and as a non-commissioned officer took part in the war against Spain. In the Army of the Eastern Pyrenees and in the Army of the Moselle he repeatedly distinguished himself for valour, and in 1796, as captain, he served in Bonaparte's Italian campaign. He accompanied Napoleon in the invasion of Styria in command of the "Guides," who formed the nucleus of the later Consular and Imperial Guard. As *chef de brigade* he next served in the Egyptian expedition. Returning to Europe with Napoleon, he was present at Marengo (1800) as second-in-command of the Consular Guard. Promoted general of division in 1802 and marshal of France in 1804, he made the most famous campaigns of the *Grande Armée* as colonel-general of the Guard Cavalry (1805, 1806, 1807). In 1805 he had received the Grand Eagle of the Legion of Honour, and in 1800 was created duke of Istria. With the outbreak of the Peninsular War, Marshal Bessièrès had his first opportunity of an independent command and his crushing victory over the Spaniards at Medina del Rio Seco (1808) justified Napoleon's choice. When disaster in other parts of the theatre of war called Napoleon himself to the Peninsula, Bessièrès continued to give the emperor the very greatest assistance in his campaign. In 1809 he was again with the *Grande Armée* in the Danube valley. At Essling his repeated and desperate charges checked the Austrians in the full tide of their success. At Wagram he had a horse killed under him. Replacing Bernadotte in the command of the Army of the North, he successfully opposed the British Walcheren expedition, and in 1811 he was back again in Spain. As Masséna's second-in-command he was present at the battle of Fuentes d'Onoro, but Napoleon who looked on him as an able commander and a true friend never detached him for very long, and in 1812 he commanded the Guard Cavalry at Borodino and in the retreat from Moscow. At the beginning of the 1813 campaign he was appointed to the command of the whole of Napoleon's cavalry. Three days after the opening of the campaign, while reconnoitring the defile of Poserna-Rippach, Bessièrès was killed by a musket-ball. As a commander, especially of cavalry, Bessièrès left a reputation excelled by very few of Napoleon's marshals, and his dauntless courage and cool judgment made him a safe leader in independent command. He was personally beloved to an extraordinary extent amongst his soldiers, and (unlike most of the French generals of the time) amongst his opponents. It is said that masses were performed for his soul by the priests of insurgent Spain, and the king of Saxony raised a monument to his memory.

His younger brother, **BERTRAND, BARON BESSIÈRES** (1773-1855), was a distinguished divisional leader under Napoleon. His last public act was his defence of the unfortunate Ney.

See A. Rabel, *Le Maréchal Bessièrès* (1903).

BESSUS, satrap of Bactria and Sogdiana under Darius III. In the battle of Gaugamela (Oct. 1, 331 B.C.) he commanded the troops of his satrapy. When Alexander pursued the Persian king on his flight to the East (summer 330 B.C.), Bessus, with some other conspirators, deposed Darius and shortly afterwards killed him. He then tried to organize a national resistance against Alexander in the eastern provinces, proclaimed himself king and took the name Artaxerxes. But he was taken prisoner in the

summer of 329. Alexander sent him to Ecbatana, where he was condemned to death.

See Arrian, iii., 30, 5; iv., 7, 3. Curt. vii., 10, 10.

BEST, WILLIAM THOMAS (1826-1897), English organist, the son of a solicitor, was born at Carlisle on Aug. 13, 1826. After holding various smaller appointments he became, in 1855, organist of St. George's Hall, Liverpool, where his performances rapidly became famous throughout England. Ill-health compelled him at last to retire in 1894. He was engaged as solo organist at all the Handel festivals at the Crystal Palace, and also as organist at the Albert Hall, where he inaugurated the great organ in 1871. He died at Liverpool on May 10, 1897.

One of the greatest of modern organists who was also a fine all-round musician, his performances of Bach's organ works were particularly fine. His own compositions for the organ, chiefly comprised in the publication entitled *Organ Pieces for Church Use*, have a strong and marked individuality, typical alike of the composer, and of the style of his own organ playing.

BESTIA, the name of a family in ancient Rome, of which the following were the most distinguished:

(1) **LUCIUS CALPURNIUS BESTIA**, Roman tribune of the people in 121 B.C., consul in 111. He was given the command against Jugurtha, but, having been heavily bribed, concluded a disgraceful peace. On his return to Rome he was tried and condemned. He is probably identical with the Bestia who went into exile (90) to avoid punishment under the law of Q. Varius, whereby those who had aided the Italian allies in their revolt were to be brought to trial (Appian, *Bell. Civ.* i. 37; Val. Max. viii. 6. 4). He is mentioned in a Carthaginian inscription as one of a board of three, perhaps an agricultural commission.

See Sallust, *Jugurtha*; Cicero, *Brutus*, xxxiv. 128; for the general history, A. H. J. Greenidge, *Hist. of Rome* (1904), vol. i pp. 346 foll.

(2) **LUCIUS CALPURNIUS BESTIA**, one of the Catilinarian conspirators, possibly a grandson of the above. He was tribune elect in 63, and it had been arranged that, after entering upon his office, he should accuse Cicero of responsibility for the impending war. This was to be the signal for revolution. The conspiracy, however, was put down and Bestia had to content himself with a violent attack upon Cicero at the close of his year of office. This Bestia is probably not the Lucius Calpurnius Bestia who was accused of bribery during his candidature for the praetorship in 57, and, in spite of Cicero's defence, was condemned. In 43 he joined Antony's party, apparently in hope of the consulship.

Sallust, *Catiline*, xvii. 43; Appian, *Bell. Civ.* ii. 3; Cicero *Ad. Q. Fr.* ii. 3, 6.

BESTIARY. The mediaeval bestiary combined the characteristics of a natural history text-book and Aesop's fables. It professed to describe the nature and habits of living creatures and drew from them far-fetched moral and religious lessons. Its descriptive portions were drawn largely from the *Hexameron* of Ambrose, the *Etymology* of Isidore, and the works of Rabanus Maurus, which themselves were based on the writings of Aristotle, Pliny and Solinus. In its earliest form it was known as *Physiologus*, that is, "the Naturalist," by which title it was denounced in a papal decree of c. 500 as written by heretics and falsely ascribed to St. Ambrose. It was also commonly attributed to St. Epiphanius (4th century). A *physiologus* seems to have been in existence as early as the 2nd century B.C., and the addition of Christian moralizations was natural in view of the many zoological metaphors found in the Bible.—"the lion of the house of Judah," "the deaf adder that stoppeth her ears," and so forth. About the beginning of the 12th century the *physiologus*, with its description of some 40 creatures, developed into the bestiary, which often described as many as 200, divided into sections under beasts, birds, reptiles and fishes, with the addition, in a few mss., of trees and stones.

The bestiary was enormously popular in the middle ages, and mss. exist in most European languages, as well as in Armenian, Ethiopic and Syriac, most belonging to the period from the 12th to the 14th century, and particularly to the first half of the 13th. A large proportion of these, beginning with a fine 10th century ms. in the Royal Library at Brussels, are illustrated, and these illustra-

tions greatly influenced contemporary art. A more or less complete bestiary is painted on two piers of the nave of the church of St. Savin-le-Mont, and another is carved round the south doorway of Alne church in Yorkshire, while isolated illustrations, painted or carved, are innumerable. Heraldry derived from this source its unicorns, yales, leopards and fire-breathing panthers; travellers, such as Jacques de Vitry, drew on the bestiaries for the wonders of the East, and preachers for their similes; while Richard de Fournival (c. 1250) wrote a *Bestiaire d'Amour*, in which he gave the symbolism a profane and amatory significance.

Regarded as natural history the bestiaries are puerile; the descriptions of even the common domestic animals show very little power of observation; those of the rarer creatures show infinite credulity on the part of the writers and an inventive ingenuity on the part of the artists, whose renderings of such beasts as the crocodile are splendidly free from the fetters of realism. Sirens, dragons, the mantichora or man-headed lion, and the caladrius, a bird which, being brought to the bedside of a sick man, would indicate his recovery or death by turning its head towards or away from him, were all accepted as being as real as rabbits. But they influenced art, literature and thought down to the days of Shakespeare, and we still condemn the hypocrisy of the "crocodile's tears" when it devours a man, and approve the "licking into shape" by which the bear fashions her cubs, born without form.

BESTUZHEV-RYUMIN, ALEXIUS PETROVICH, COUNT (1603–1768), grand chancellor of Russia, the second son of Count Peter Bestuzhev, the early favourite of the empress Anne, was born at Moscow and educated abroad, with his elder brother Mikhail, at Copenhagen and Berlin. He served his apprenticeship to diplomacy by Peter the Great's orders, at the Congress of Utrecht (1712) under Prince Kurakin, and in the service of the elector of Hanover, whom he followed to London when he became George I. of England. After a short service at the court of Anne, duchess of Courland, he was sent to Copenhagen in 1721 as Russian minister. The death of Peter the Great in 1725 prevented his advancement, and it was only in 1739, at 46 years of age, that he was recalled to Russia by the favour of Biren. After Biren's fall, he was for a short time imprisoned at Schlüsselburg.

His chance came when the empress Elizabeth, immediately after her accession, appointed him vice-chancellor. For the next 20 years, during a period of exceptional difficulty, he practically controlled the foreign policy of Russia. Bestuzhev rightly recognized that the interests of France and Russia in Turkey, Poland and Sweden were diametrically opposed, and Russia could never hope to be safe from the intrigues of France in these three borderlands. It was, therefore, the basic policy of Bestuzhev to bring about a quadruple alliance between Russia, Austria, Great Britain and Saxony, to counterpoise the Franco-Prussian league. But he was on dangerous ground. The empress herself was averse from an alliance with Great Britain and Austria, whose representatives had striven to prevent her accession; and many of her personal friends, in the pay of France and Prussia, took part in innumerable conspiracies to overthrow Bestuzhev. Nevertheless, step by step, Bestuzhev, aided by his elder brother Mikhail, carried out his policy. On Dec. 11, 1742, a defensive alliance was concluded between Great Britain and Russia. Bestuzhev had previously rejected with scorn the proposals of the French government to mediate between Russia and Sweden on the basis of a territorial surrender on the part of the former, and he conducted the war so vigorously that by the end of 1742 Sweden lay at the mercy of the empress. At the peace congress of Åbo (Jan.–Aug. 1743) he insisted that the whole of Finland should be ceded to Russia, by way of completing the testament

of Peter the Great. But the French party contrived to get better terms for Sweden, by appealing to the empress's fondness for the house of Holstein. The Swedes, at the desire of Elizabeth, accepted Adolphus Frederick, duke of Holstein, as their future king, and, in return, received back part of the duchy of Finland. Nor could Bestuzhev prevent the signing of a Russo-Prussian defensive alliance (March 1743); but he deprived it of all political significance by excluding from it the proposed guarantee of Frederick's Silesian conquests. Moreover, through Bestuzhev's efforts, the credit of the Prussian king (whom he rightly regarded as more dangerous than France) at the Russian court fell steadily, and the vice-chancellor prepared the way for an alliance with Austria by acceding to the treaty of Breslau (Nov. 1, 1743). A bogus conspiracy, however, got up by the Holstein faction, aided by France and Prussia, who persuaded Elizabeth that the Austrian ambassador was intriguing to replace Ivan VI. on the throne, alienated the empress from Austria for a time; and Bestuzhev's ruin was regarded as certain when, in 1743, the French agent, the marquis de La Chétardie, arrived to reinforce his other enemies. But he found a friend in need in M. L. Vorontsov, the empress's confidant, who shared his political views. Still his position was most delicate, especially when the betrothal between the grand-duke Peter and Sophia of Anhalt-Zerbst (afterwards Catherine II.) was carried through against his will, and Elizabeth of Holstein, the mother of the bride, arrived in the Prussian interest to spy upon him. Frederick II., conscious of the instability of his French ally, was now eager to contract an offensive overthrow of Bestuzhev. But Bestuzhev at last convinced the empress that Chétardie was an impudent intriguer, and on June 6, 1744, Chétardie was ordered to quit Russia within 24 hours. Five weeks later Bestuzhev was made grand chancellor (July 15). Before the end of the year Elizabeth of Holstein was also expelled from Russia, and Bestuzhev was supreme.

The attention of European diplomacy at this time was concentrated upon the king of Prussia, whose insatiable acquisitiveness disturbed all his neighbours. Bestuzhev's offer to attack Prussia if Great Britain would guarantee subsidies was rejected in 1745. Then he turned as a last resort to Austria, and on May 22, 1746, an offensive and defensive alliance was concluded between the two powers manifestly directed against Prussia. In 1747 alliances were also concluded with Denmark and the Porte, and a closer agreement was reached with England by the Treaty of St Petersburg (Dec. 9, 1747).

Bestuzhev's triumph coincided with the peace congress of Aix-la-Chapelle, which altered the whole situation of European politics and introduced fresh combinations, the breaking away of Prussia from France and a rapprochement between England and Prussia, with the inevitable corollary of an alliance between France and the enemies of Prussia. Bestuzhev's violent political prejudices at first prevented him from properly recognizing this change. His Anglomania also misled him. His enemies, headed by his elder brother Mikhail and the vice-chancellor Vorontsov, powerless while his diplomacy was faultless, quickly took advantage of his mistakes. When, on Jan. 16, 1756, the Anglo-Prussian, and on May 2 the Franco-Austrian alliances were concluded, Vorontsov advocated the accession of Russia to the latter league, whereas Bestuzhev insisted on a subsidy treaty with Great Britain, which was ratified, against the empress's real wishes, on Feb. 1, 1756. But his influence was now on the wane. The totally unexpected Anglo-Prussian alliance had justified the arguments of his enemies that England was impossible, while his hatred of France prevented him from adopting the only alternative of an alliance with her. To prevent underground intrigues, Bestuzhev now proposed the erection of a council of ministers, to settle all important affairs, and at its first session (March 14–30) an alliance with Austria, France and Poland against Frederick II. was proposed though Bestuzhev opposed any composition with France. Elizabeth maintained that the conclusion of the Anglo-Prussian treaty nullified Russian engagements with England. He endeavoured to support his failing credit by a secret alliance with the grand-duchess Catherine, whom he hoped after the Empress's death to make regent for her son, passing over Peter, from whom

Bestuzhev expected nothing good either for himself or for Russia. The negotiations were conducted through the Pole Stanislaus Poniatowski. The accession of Russia (Dec. 31, 1756) to the anti-Prussian coalition was made over his head and the cowardice and incapacity of Bestuzhev's friend, the Russian commander-in-chief, Stephen Apraksin, after the battle of Gross-Jagersdorf (1757), was made the pretext for overthrowing the chancellor. His unwillingness to agree to the coalition was magnified into a determination to defeat it. He was deprived of the chancellorship and condemned to death, which was commuted to banishment to his estate at Gorstovo (April 1759), where he remained till the accession of Catherine II., who recalled him to court and created him a field-marshal. But he took no leading part in affairs and died on April 21, 1768, the last of his race.

See *The Sbornik of the Russian Historical Society*, vols., 1, 3, 5, 7, 12, 22, 26, 66, 70, 80, 81, 85-86, 91-92, 96, 99, 100, 103 (1870, etc.), *Politische Correspondenz Friedrichs des Grossen*, vols. 1-21 (1870-1904); R. Nisbet Bain, *The Daughter of Peter the Great* (1896).

BESTUZHEV-RYUMIN, MIKHAIL PETROVICH, COUNT (1688-1760), Russian diplomatist, was educated at Berlin, and was sent by Peter the Great to represent Russia at Copenhagen in 1705. In 1720 he was appointed resident at London at a time when the English court was greatly inflamed against Peter, who was regarded as a dangerous rival in the Baltic; and Bestuzhev was summarily dismissed for protesting against the lately formed Anglo-Swedish alliance. On the conclusion of the peace of Nystad in 1721 he was sent as ambassador to the court of Stockholm. His first official act was the signing of a defensive alliance between Russia and Sweden for 12 years in 1724. He was successively transferred to Warsaw (1726) and to Berlin (1730), but returned to Stockholm in 1732. How far Bestuzhev was concerned in the murder (June 28, 1739) of the Swedish diplomatic agent Sinclair in Silesia on his journey home from Constantinople, it is difficult to say. It is certain that Bestuzhev sent information to his court of Sinclair's mission, which was supposed to be hostile to Russia, and even supplied the portrait of the envoy for recognition. The Swedish authorities are unanimous in describing Bestuzhev as the arch-plotter in this miserable affair; yet, while the active agents were banished to Siberia, Bestuzhev was not even censured. The Sinclair murder led ultimately to the Swedish-Russian War of 1741, when Bestuzhev was transferred first to Hamburg and subsequently to Hanover, where he endeavoured to conclude an alliance between Great Britain and Russia. On his return to Russia in 1743, he was made grand marshal, and married Anna, the widow of Paul Yaguzhinsky, Peter the Great's famous pupil. A few months later his wife was implicated in a false conspiracy got up by the French ambassador, the marquis de La Chétardie, to ruin the Bestuzhevs (see BESTUZHEV-RYUMIN, ALEXIUS), and after a public whipping, had her tongue cut out and was banished to Siberia. Thither Bestuzhev had not the manhood to follow her, but went abroad, and subsequently resumed his diplomatic career. His last and most brilliant mission was to Versailles, shortly after the conclusion of the coalition against Frederick the Great. He died in Paris on Feb. 26, 1760.

See Robert Nisbet Bain, *The Daughter of Peter the Great* (1899); Mikhail Sergievich, *History of Russia* (Rus.), vols. xv.-xvii. (2nd ed., 1897). (R. N. B.)

BETAÏNE (*syn* Acetobetaine, Lycine, Oxyneurine) was first discovered in sugar-beet, *Beta vulgaris* (C. Scheibler, 1869). It occurs in cotton seed, in barley and wheat shoots, in vetch and in many other plants often associated with choline. It is also found in cuttlefish and crayfish and in mussels and other shell-fish.

Betaïne is obtained synthetically by oxidizing choline (O. Liebreich, 1869), or by heating glycine (aminoacetic acid) with methyl iodide and alkali (P. Griess, 1875), and its hydrochloride is synthesised by heating together trimethylamine and chloroacetic acid (Liebreich). The free hydrated base, which is the methyl hydroxide of dimethylglycine, $\text{HO N}(\text{CH}_3)_2\text{CH}_2\text{CO}_2\text{H}$, crystallizes from alcohol in deliquescent crystals readily soluble in water. On heating it readily loses water, passing into an internal anhydride (I.), which has the characteristic betaine structure and is the prototype of many more complex betaines.

Formula I. represents the chemical structure hitherto ascribed to betaine in which quinquevalent nitrogen and bivalent oxygen are united by a non-polar or co-valent linking, but it has also been suggested by Paul Pfeiffer (1922) that this anhydride formation is due to a polar or electrovalent association of the two atoms as indicated by formula II. According to this hypothesis betaine contains two ions of opposite sign (positive quaternary ammonium ion and negative carboxylate ion) bound together by a methylene group.

The term betaine is also employed generically to designate a large group of substances having the foregoing chemical structure. Several of these betaines are obtainable from natural sources, two examples of which are given.

Nicotinic acid (pyridine-3-carboxylic acid), derivable from the tobacco alkaloid, crystallizes in needles and melts at 232°C . It is soluble in hot water and in alcohol, but not in ether. It may be converted by the successive action on its alkali salt of methyl iodide and moist silver oxide into a betaine which is identical with the alkaloid *trigonelline* (III) discovered by E. Jahns (1885) in the seeds of fenugreek (*Trigonella foenum graecum*).

γ -Butyrobetaine (IV.), obtained by Taheda (1910) from dog's urine after phosphorus poisoning, is probably identical with one of Brieger's ptomaines or putrefaction bases, it was first synthesised by Willstätter (1902).

Closely related to betaine are the bases, choline, neurine and muscarine. Choline (bilinearine), $\text{HO CH}_2\text{CH}_2\text{N}(\text{CH}_3)_3\text{OH}$, which was first isolated by A. Strecker in 1862, is found in the bile, in brain substance, and in yolk of egg in the form of lecithin, a complex ester of glycerin with phosphoric acid and the fatty acids. It is also found in combination with sinapic acid in sinapin, the glucoside obtained from white mustard, and can be obtained from this glucoside by hydrolysis with baryta water. Synthetically prepared by the action of trimethylamine on an aqueous solution of ethylene oxide (A. Wurtz, 1868), it forms deliquescent non-poisonous crystals of strongly alkaline reaction, and absorbs carbon dioxide from the air.

Neurine, trimethylvinylammonium hydroxide, $\text{CH}_2\text{CH N}(\text{CH}_3)_3\text{OH}$, a very poisonous, crystalline ptomaine base produced by the putrefaction of albumin, may be prepared by the action of moist silver oxide on ethylene dibromide and trimethylamine.

Muscarine, an exceedingly poisonous substance found in many fungi, may be obtained synthetically by oxidizing choline with dilute nitric acid (O. Schmiedeberg, 1876). Its constitution is generally represented as $\text{CH}(\text{OH})_2\text{CH}_2\text{N}(\text{CH}_3)_3\text{OH}$. The name muscarine is also given to an oxazine colouring matter.

See G. Barger, *The Simpler Natural Bases* (1914), P. Pfeiffer, "On the theory of Betaines," *Berichte der deutschen chemischen Gesellschaft* (1922).

BET, BETTING: see BETTING TAX GAMING and WAGERING.

BETA RAYS, the stream of electrons (see ELECTRON) ejected from certain radioactive substances (see RADIOACTIVITY; and ELECTRICITY, CONDUCTION OF: in Gases).

BETE, a people living in independent villages on the French Ivory Coast, in the valley of the Sassandra and its eastern affluents, with the same social and family characteristics as the Gouro. They practise husbandry and arboriculture and are animists.

See G. Joseph, *La Côte d'Ivoire* (1917).

BETELGEUSE, the brightest star in the constellation Orion (α Orionis). It is yellowish-red, and is thus easily distinguished from the other important stars in the constellation, which are white. Betelgeuse is a multiple star, being an irregular variable, sometimes above and sometimes below the first magnitude. It was the first star whose apparent diameter was measured, in 1920, by

Michelson's interferometer method. (See INTERFEROMETER.) It is of spectral type M, its spectrum showing the flutings due to titanium oxide. (See ORION; SPECTROSCOPY and STAR.)

BETEL NUT. The name betel is applied to two different plants, which in the East are very closely associated in the purposes to which they are applied. The betel nut is the fruit of the Areca or betel palm, *Areca Catechu*, and the betel leaf is the produce of the betel vine or pan (*Piper Betel*), a plant allied to that which yields black pepper. The areca palm is a native of Malaya and is extensively cultivated in the south of India, Ceylon, Siam, the Malay Archipelago and the Philippine islands. It is a graceful tree with a straight, slender, unbranched stem reaching 40 or 50 ft. in height and about 1½ ft. in circumference, and bearing a crown of six to nine very large spreading pinnate fronds. The fruit is about the size of a small hen's egg, and within its fibrous rind is the seed or so-called nut, the albumen of which is very hard, and has a prettily mottled grey and brown appearance. The chief purpose for which betel nuts are cultivated and collected is for use as a masticatory—their use in this form being so widespread among oriental nations that it is estimated that one-tenth of the whole human family indulge in betel chewing. For this use the fruits are annually gathered between the months of August and November, before they are quite ripe, and deprived of their husks. They are prepared by boiling in water, cutting up into slices, and drying in the sun, by which treatment the slices assume a dark brown or black colour. When chewed a small piece is wrapped up in a leaf of the betel vine or pan, with a pellet of shell lime or chunam; and in some cases a little cardamom, turmeric or other aromatic is added. Mastication of the material causes a copious flow of brick-red saliva, which dyes the mouth, lips and gums. The habit blackens the teeth, but is asserted by those addicted to it to strengthen the gums, sweeten the breath and stimulate the digestive organs. Betel nuts are further used as a source of catechu, which is procured by boiling the nuts in water; the catechu is then extracted.

BETHANY (mod *El-'Azariyeh*, a corruption of Lazarion), a small village pleasantly set amongst fruit trees and cornfields on the eastern slope of the Mount of Olives: pop. 500, almost entirely Mohammedan. It was the residence of Lazarus and his sisters and much favoured by Jesus. An ancient tower marks the site of a convent of Benedictine nuns founded by Queen Millicent in A.D. 1147 and abandoned when Saladin took Jerusalem in 1187. A church was shown at this spot in the 4th century. Underneath is a vault opening on to a tomb-chamber claimed to be that of Lazarus. The original entrance was through the church, but when the church was converted into a mosque in the 16th century a separate entrance was excavated. The so-called house of Martha and Mary is some 30 yd east of the tower. A Bethany (or Bethabara) beyond Jordan, which cannot, however, be identified, is mentioned in John i. 28.

On the origin of the name see W. F. Albright, *Annual of American School of Oriental Research*, 158 seq. (1924).

BETHEL, a village on the watershed of the Judæan hill-country, 11 m. N. of Jerusalem and 2,900 ft. above sea-level; pop. 446, Muslim. Bethel ("House of God"), now called Beitin, but originally called Luz (Gen. xxviii. 19), was early accounted a holy place, due, perhaps, to the existence near by of a natural stone circle. Here Abraham pitched his tent and built an altar (Gen. xii. 8); here Jacob had his vision (Gen. xxviii. 10 sqq.); and here, too, at one time, was found the ark of the covenant (Judg. xx. 27). It was visited yearly by Samuel when he went on circuit to judge Israel (I. Sam. vii. 16). Jeroboam welcomed the opportunity to exploit its sacred associations for political ends, and Bethel became a royal and national shrine for the northern kingdom (I. Ki. xii.; Amos vii.). Situated on the frontier between the two kingdoms it passed eventually to Judah. Josiah destroyed its altar and desecrated its site (II. Ki. xxiii. 15). It was one of the strong places of Judah fortified by Bacchides (I. Macc. ix. 50). Remains of churches (12th and 6th centuries) are found here and at Burj Beitin, a hill a short distance off to the south-east.

See G. Sternberg, "Bethel," *Zeitschr. Deutsch. Paläst. Vereins*, 1 sqq. (1915); J. E. McFadyen, "Bethel," *Expositor* 241 sqq. (1924).

BÉTHENCOURT, JEAN DE (c. 1360–1422), French explorer, sailed from La Rochelle on May 1, 1402, with two ships commanded by himself and Gadifer de la Salle to conquer the Canary Islands. Failing in a first attempt he secured help from Henry III., king of Castile, and the title of "king." There was some disagreement with Gadifer de la Salle, who had seized Lanzarote, but Béthencourt had Henry III.'s support against his rival. He visited France in 1405 to secure new colonists, and in 1406 returned once more, to spend the rest of his life in Normandy. His *Le Canarien, livre de la conquête et conversion des Canaries*, an untrustworthy narrative of his "conquest," was published with introduction and notes by G. Gravier (Rouen, 1874), and an English translation was edited by R. H. Major for the Hakluyt Society (1872).

BETHESDA, an urban district of Carnarvonshire, North Wales, 5 m. from Bangor, by a branch of the L.M.S. railway. Population (1921) 4,132. It lies near the lower end of the fine Nant Ffrancon (valley of the Ogwen stream). The scriptural name is due, as often in Wales, to the village or hamlet taking its title from the Nonconformist church. Here are extensive slate quarries belonging to Lord Penrhyn. A narrow-gauge railway connects these with Port Penrhyn, at the mouth of the stream Cegid (hemlock, "*cicuta*"), which admits the entry of vessels of 300 tons to the quay at low water.

BETHESDA, the "House of Mercy," John v. 2, better perhaps Bethzatha or Bethsaida, a pool or public bath in Jerusalem, where miraculous cures were believed to be performed. The following identifications have been suggested: *Birket Isra'el*, near St. Stephen's gate; a large cistern, near St. Anne's church; the "Twin Pools," north of the Haram (the ancient Temple area); the *Hammâm esh-Shifâ*—or pool of healing, west of the Haram; the Virgin's fountain, south of the Haram; and the "Pool of Siloam." Which, if any, of these identifications is correct, it is impossible to say.

See E. W. G. Masterman, "The Pool of Bethesda," in *Palestine Exploration Fund Quarterly Stat.*, 91 seq. (1921), R. A. S. Macalister, *A Century of Excavation in Palestine*, 137 seq. (1925).

BETH-HORON ("the place of the hollow way"), the name of two neighbouring villages, upper and lower Beth-horon, on the ascent from the coast plain of Palestine to the high tableland of Benjamin, which was until the 16th century the high road from Jerusalem to the sea. The two towns thus played a conspicuous part in Israelitish military history (see Josh. x. 10; I. Sam. xiii. 18; I. Ki. ix. 17; I. Macc. iii. 13–24, vii. 39 sqq., ix. 50). Josephus (*Bell. Jud.* ii. 19) tells of the rout of a Roman army under Cestius Gallus in A.D. 66. The Talmud states that many rabbis were born in the place. It is now represented by *Beit 'Ur-el-fôkâ* and *Beit 'Ur-el-tahîâ*, around which much fighting took place in the attacks on Jerusalem, November to December 1917.

See T. Oelgarte, "Die Bethhoronstrasse," *Palästina Jahrbuch*, 73 sqq. (1918).

BETHLEHEM, a town 5 m. S. of Jerusalem on eastern spur of watershed; altitude 2,500 ft. (Heb. "house of bread" or "of Lahamu" [deity]; also called *Ephrathah* [Mic. v., Ruth iv.], but this is perhaps a district name).

History.—Garrisoned by the Philistines in the time of Saul (II. Sam. xxiii. 14), Bethlehem was the early home of David and of his nephews Joab, Abishai and Asahel. Rehoboam fortified the town (II. Chron. xi. 6), and in its great khan (Chimham) the murderers of Gedaliah rested (586 B.C.) on their flight to Egypt (Jer. xli. 7). It was reoccupied after the captivity by Bethlehemites (Ezra ii. 21). The Bethlehem district is the scene of the story of Ruth. As the birthplace of Jesus it emerged gloriously from the obscurity into which it had fallen. Justin Martyr (c. A.D. 150) describes the scene of the birth as a "cave" near the village. In A.D. 315 Bethlehem was little more than a wilderness. Justinian enclosed the town with a wall (531). The Persians spared it in 614 and the Arabs in 636. The crusaders in their advance on Jerusalem occupied it at the invitation of the inhabitants (1099). It was erected into a Latin bishopric in 1110, passed to the Muslims in 1187 and was restored to the Christians through treaty (1229–44). In the 14th century the Greek Church made it an

episcopal see and in the 17th the Armenian did likewise. In 1489 the wall and towers were demolished and the moat filled in by order of the sultan, whilst in 1834 Ibrahim Pasha laid waste the Muslim quarter as punishment for a Muslim insurrection. It fell into the hands of the British at the time of the capture of Jerusalem (1917).

Church of the Nativity.—Bethlehem was evidently early recognized as a sacred site by Christians since Hadrian felt impelled to desecrate it (c. 132). Constantine in 330 erected a basilica (S. Maria a Praesepio) to which Justinian added. Convents of the Greek, Latin and Armenian churches closely surround it. Disputes for the possession of the sanctuary and precedence in worship occupied the Churches for centuries, leading at times to disorderly scenes. The Grotto of the Nativity is a crypt occupying the centre of the transept and approached by steps leading down from either side of the choir. Fitted into the marble paving is a star with around it the words *Hic de Virgine Maria, Jesus Christus natus est*. Round the star burn night and day 15 lamps—six Greek, five Armenian, four Latin. Mass is celebrated here every day by the Greeks and Armenians. The Oratory of the Manger and the Altar of the Magi bear their witness to other sacred spots. From the Grotto access is obtained to the tombs of Eusebius of Cremona (d. 422), Paula (d. 404) and Jerome (d. 420), and to the cell, now a chapel, where Jerome made his famous translation of the scriptures. The Vulgate mosaics of the 12th century still adorn the church, and King Edward IV. supplied the oak used in restoration of the roof (1482). A wall erected by the Greeks to separate the nave from the transept in 1842 was removed in 1918 by order of the governor of Jerusalem with the concurrence of the Churches concerned.

Modern Town.—Bethlehem has a population of 6,600 (5,800 Christians), and is a prosperous town with many good houses. The centre of a fertile district its wine is amongst the best in Palestine. The chief occupation, apart from husbandry, is the manufacture and sale of religious mementoes made from mother-of-pearl, olive wood or "Dead Sea stone." The women of Bethlehem wear a special garb. A large number of schools and charitable institutions represents the activities of a wide variety of religious sects (There was a small village in Zebulun, 7m. N of Nazareth with the same name).

BETHLEHEM, a city of Pennsylvania, U.S.A., in Northampton and Lehigh counties, on the Lehigh river, 50m north-west of Philadelphia. It is on the William Penn highway and the Bethlehem pike (one of the oldest highways in the country); is served by the Central Railroad of New Jersey, the Lehigh Valley, the Lehigh and New England, the Philadelphia, Bethlehem and New England, and the Reading railways; and is traversed by the Lehigh Coal and Navigation Company canal, running from the anthracite fields to tide-water. The area of the city is 17.8sq.m. Its population was 54,149 in 1920 of which about a fifth were foreign born; and was estimated at 66,000 in 1927.

The city is built on hills on both sides of the river, and commands delightful views as far as the Blue mountains, 20m to the north. Three bridges connect the north and south sides. The Hill-to-Hill bridge, built in 1921 to 1924 at a cost of \$3,500,000, has eight approaches at either end, crosses four railroads, the river, and the canal. The beautiful stone community buildings of the Moravians were erected between 1742 and 1774, and their present church dates from 1803. A conspicuous modern structure is the Liberty high school, standing in 16 acres of playgrounds. Lehigh university (chartered 1866) occupies a campus of 180ac. on the slope of South mountain. It has an annual enrolment of more than 1,500 students and an endowment of about \$5,000,000.

Steel and silk are the outstanding industries. The Bethlehem Steel Corporation has its main office and parent plant in Bethle-

hem. Along the south bank of the river for a distance of over 3m. extend the comprehensive plants, which produce pig-iron, steel of all types, coke and its by-products, engines, machinery, ordnance, and many other steel products. Other corporations are engaged in the fabrication and erection of structural steel, notably anthracite breakers and washeries. The silk industry, with an annual output valued at \$50,000,000, includes the manufacture of broad silk, silk throwing and hosiery mills. The assessed valuation of property for 1928 was \$65,-

711,532. Bank clearings in 1926 were \$240,871,752.

BY COURTESY OF THE BETHLEHEM CHAMBER OF COMMERCE

THE FIRST WATER WORKS IN THE UNITED STATES, AT BETHLEHEM
Built of rough stone, this building still stands and is used as a dwelling. The original water pipes were made of hemlock logs

Bethlehem was founded in Dec. 1741, by religious exiles from Bohemia and Moravia, who came to America under the leadership of Bishop David Nitschmann, influenced by their Saxon patron, Count Zinzendorf, in search of freedom and to do missionary work among the Indians and Negroes. They developed their industries under a communistic system of labour, but in 1763 distributed most of them among the members of the congregation. During the revolution, Bethlehem was a thoroughfare for troops; and in 1776 and again in 1777 one of the community buildings was commandeered for a military hospital, where over 700 soldiers died. For a short time the Sun Inn, built in 1758 and still in service, was the refuge of a part of the Continental congress. The Moravians established a day-school (later developed into a college), a theological seminary, and in 1746 the first boarding school for girls in America (now a college); all are still functioning. Their love of music gave Bethlehem an unique distinction. An orchestra of strings, wind and brass was used in the church services before 1750. Since 1754 a choir of trombones has played at funerals, and from the belfry of the church has announced festival days and national holidays and the death of members of the church. An orchestra and a chorus (first the Collegium Musicum, which gave the first performance in America of Haydn's *Creation*, and later the Philharmonic Society) were in existence almost continuously until 1885. After a lapse of a few years choral music was revived by the organist, J. F. Wolle, and under his direction a national reputation was gained for the rendering of the works of Bach. Since 1895, except during the years of Dr. Wolle's absence (1906-12), an annual Bach festival of two days or more has been held in May, drawing music lovers from all parts of the world.

The borough of Bethlehem was incorporated in 1845. West Bethlehem was annexed in 1904. The city was formed in 1917 by the consolidation of Bethlehem and South Bethlehem, and in 1920 Northampton Heights was annexed.

BETHLEHEMITES, a name borne at different times by three orders in the Roman Catholic Church (1) A community of friars at Cambridge, in 1257, whose habit was distinguished from that of the ordinary Dominicans by a five-rayed red star (in reference to Matt ii 9 f) (2) An order of knighthood similar to the Knights of St. John, established by Pius II in 1459 to resist the inroads of the Turks (3) The Bethlehemite Order of Guatemala, a nursing community founded in 1650 by Pedro Betancourt (d 1667), and raised to an order by Innocent XI in 1687. They spread throughout Central America and Mexico and as far south as Lima, and with the corresponding order of sisters were conspicuous for their devotion during times of plague and other contagious diseases. This order became extinct about 1850.

BETHLEHEM STEEL CORPORATION was organized in New Jersey on Dec 10, 1904, to acquire the stock of Bethlehem Steel Company (Pa) and of several other companies owning ship-building plants. Its only steel plant (at Bethlehem, Pa) then had an annual ingot capacity of 190,000 tons and manufactured principally armor plate and other ordnance. By large cash expen-

ditures for construction and by purchases of properties of other companies including the Pennsylvania Steel Company and Maryland Steel Company in 1917, American Iron and Steel Manufacturing Company in 1917, Lackawanna Steel Company in 1922 and Midvale Steel and Ordnance Company and Cambria Steel Company in 1923, the steel making capacity of the corporation has since its organization been increased to 7,900,000 tons representing 12.85% of the present capacity of the United States. It is now the second largest steel company in the world and produces all of the principal commercial steel products, having nine steel and manufacturing plants, all located in Pennsylvania, Maryland, New York, Delaware and New Jersey. It also manufactures many special types of machinery, builds railroad cars (both passenger and freight) and has extensive shipbuilding and ship repair facilities on both the Atlantic and Pacific coasts of the United States. The corporation is virtually self-contained, owning large reserves of all of its important raw materials. Its capital upon its organization was \$30,000,000 of stock and \$11,750,000 of bonds. Its present capital consists of \$97,000,000 of preferred stock, \$180,000,000 of common stock, \$204,000,000 of funded debt and \$124,000,000 of surplus. (E. G. G.)

BETHLEN, GABRIEL (GÁBOR) (1580–1629), prince of Transylvania, the most famous representative of the Iktári branch of a very ancient Hungarian family, was born at Ilyé, and educated at Szarhegy, at the castle of his uncle András Lázár. Thence he was sent to the court of Prince Zsigmond Báthory, whom he accompanied on his famous Wallachian campaign in 1600. Subsequently he assisted Stephen Bocskay to mount the throne of Transylvania (1605), and remained his chief counsellor. Bethlen also supported Bocskay's successor, Gabriel Báthory (1608–1613), but the prince became jealous of Bethlen's superior abilities, and he was obliged to take refuge with the Turks. He was at Adrianople when the sultan proclaimed him prince of Transylvania, a choice confirmed by the Estates of Transylvania in September shortly before the murder of Báthory. On Oct. 13, 1613, the diet of Klausenburg confirmed the choice of the sultan. In 1615 Bethlen was also officially recognized by the emperor Matthias. Bethlen no sooner felt firmly seated on his throne than he seized the opportunity presented to him by the outbreak of the Thirty Years' War to take up arms in defence of the liberties and the constitution of the extra-Transylvanian Hungarian provinces. While Ferdinand was occupied with the Bohemian rebels, Bethlen led his armies into Hungary (1619), and soon won over the whole of the northern counties, even securing Pressburg and the Holy Crown. Negotiations for peace were opened at Pressburg, Kaschau and Bratislava successively, but came to nothing because Bethlen insisted on including the Bohemians in the peace, whereupon (Aug. 20, 1620) the estates of north Hungary elected him king. Bethlen accepted the title but refused to be crowned, and war was resumed, till the defeat of the Czechs at the battle of the White Mountain gave a new turn to affairs. Bethlen then concluded the peace of Nikolsburg (Dec. 31, 1621), renouncing the royal title on condition that Ferdinand confirmed the peace of Vienna, 1606 (which had granted full liberty of worship to the Protestants) and engaged to summon a general diet within six months. For himself Bethlen secured the title of prince of the Empire, the seven counties of the Upper Theiss, and the fortresses of Tokaj, Munkács and Ecsed. Subsequently Bethlen twice (1623 and 1626) took up arms against Ferdinand as the ally of the anti-Hapsburg Protestant powers. The first war was concluded by the peace of Vienna, the second by the peace of Pressburg, both confirmatory of the peace of Nikolsburg. After the second of these insurrections, Bethlen attempted a rapprochement with the court of Vienna on the basis of an alliance against the Turks and his own marriage with one of the Austrian archduchesses; but Ferdinand rejected his overtures. Accordingly, on his return from Vienna he married Catherine, the daughter of the elector of Brandenburg, and sister-in-law of Gustavus Adolphus of Sweden, who, he hoped, would help him to obtain the Polish crown. He died before he could accomplish any of his great designs (Nov. 15, 1629), having previously secured the election of his

wife Catherine as princess. His first wife, Susannah Károlyi, died in 1622.

Gabriel Bethlen was certainly one of the most striking and original personages of his century. A zealous Calvinist, whose boast it was that he had read the Bible 25 times, he was nevertheless no persecutor, and even helped the Jesuit Kaldy to translate and print his version of the Scriptures. He was in communication all his life with the leading contemporary statesmen, so that his correspondence is one of the most interesting and important of historical documents.

His correspondence was published, ed. by Sándor (Budapest, 1866) and Szilágyi (1879). For his life see Anton Gindely *Acta et documenta historiam Gabrielis Bethleni illustrantia* (1890); Ignée-Acsády *Gabriel Bethlen and his Court* (1890).

BETHLEN, STEPHEN BETHLEN DE, COUNT (1874–), Hungarian statesman, was born Oct. 8, 1874, at Cornesti (Gernyeszag), Transylvania. His father, Count Stephen Bethlen, was a member of the famous family that gave Gabriel Bethlen, Prince of Transylvania, to Hungarian history. His mother was Countess Helen Teleki. The son went to school at the Theresianum in Vienna, then studied law at the University of Budapest and also obtained the diploma of the academy of agriculture at Magyaróvár. He then travelled in Europe and the United States and on his return home took charge of the management of his large estates—estates which were sequestered after the Treaty of Peace by the Rumanian Government.

In 1901 he was elected to parliament as a member of the Liberal opposition. Prior to the World War, Count Tisza offered Count Bethlen a portfolio in the cabinet, which was declined. The Emperor Francis Joseph appointed him a privy councillor, but until he became prime minister in 1921 he never held office.

After the Hungarian revolution of Nov. 1918, and during the ensuing régime of Count Michael Károlyi, Count Bethlen took a leading part in creating the counter-revolutionary organization which, when the Bolsheviks came into power, took shape as the emergency Government of Szeged, and of which he was the chief representative in Vienna. (See HUNGARY)

When the Hungarian Peace Delegation went to Paris Count Bethlen was one of the principal delegates, and it was under his personal direction that the Hungarian memorandum in relation to Transylvania was drafted. Ten months after the Treaty of Trianon had been signed, and a few days after King Charles had made his first fruitless effort to regain the throne of Hungary, Count Bethlen accepted the invitation of the regent, Admiral Horthy, to form a cabinet in consequence of the resignation of Count Paul Teleki.

As Prime Minister.—On April 14, 1921, Count Bethlen became prime minister. Few men in the political history of Europe had so often and for so long refused high office: few had ever accepted it under such thankless and discouraging conditions. The Succession States, with overwhelming armies, threatened the occupation of Hungary on the ground that the recent attempt of King Charles to regain the throne endangered the Peace Settlement. The great Allied Powers were in much the same mood. On the other hand the Hungarian people were seething with indignation over what they considered to be the injustice and humiliation of the dictated Treaty of Peace. In this crisis, with no cabinet experience, bitterly opposed both by royalist and socialist extremists, Count Bethlen dared to lead his country. He succeeded at home because of his unquestioned patriotism, moderate views and political sagacity: abroad his powers of reasoning, fairness and flair for negotiation received quick recognition.

In Oct. 1921 he achieved a notable diplomatic success by concluding at the Conference of Venice an amicable agreement with the Austrian Chancellor regarding western Hungary (Burgenland). For months Austria and Hungary had been on the verge of hostilities over the ownership of this territory which under the Peace Treaty had been allotted to Austria. In consequence of the Venice conference the important town of Sopron and its environs, after a plébiscite, were ceded back to Hungary. In the same month—Oct. 1921—Count Bethlen had to face another national crisis when King Charles for the second time

endeavoured to regain his throne. The firmness shown by Count Bethlen in concert with the regent undoubtedly saved Hungary from national extinction.

The elections rendered necessary by the expiration of the mandates of the existing Parliament returned Count Bethlen to power in June 1922. This second Government of Count Bethlen completed the scheme of land reform, re-established and reconstituted the upper house, created a new basis of suffrage, approved radically new standing orders for Parliament, ratified agreements settling outstanding political and economic difficulties with neighbouring states, and last but not most important of all achieved the financial and economic salvation of Hungary. The courage of Count Bethlen in accepting office in his country's darkest days had been rewarded.

The economic reconstruction of Hungary became possible almost solely owing to Count Bethlen's personality and to his individual efforts. In the spring of 1923 he appealed in Paris to the Reparation Commission so to suspend the Reparation sword of Damocles as to permit Hungary to remain alive. At that time the state was faced with bankruptcy and the people with ruin. Count Bethlen took his political fortune in his hand, and pledged his proud countrymen to accept the financial control of the League of Nations. The Reparation Commission, by the casting vote of France, refused Count Bethlen's request. He went on a desperate pilgrimage to London, Paris and Rome to get that decision reconsidered. He was a stranger to practically all the Allied Ministers, yet thanks to his transparent integrity and reasonableness he succeeded. Within 18 months the Reparation Commission had suspended the Reparation charges, the League of Nations had arranged a plan of reconstruction, the Hungarian Parliament had agreed to all the League's demands of control, and a loan of about £11,000,000 was floated successfully on the money markets of the world—principally in London and mainly through British support. That would never have been achieved if Count Bethlen had been less patient or determined.

By June 1926, thanks largely to the self-sacrifice of the Hungarian people and their willingness to follow the lead of their prime minister, the success of the reconstruction scheme was achieved and the League Commissioner-General withdrew from Budapest. In December 1927 the last part of the League loan was handed over to the Hungarian Government for investment purposes. The Budget was in perfect equilibrium and the currency established.

The discovery at the beginning of 1925 of a plot to forge French bank notes, organized by Prince Windisch-Grätz and M. Nádosy, Chief of the Budapest Police, with the alleged object of financing the recovery of some of Hungary's lost possessions, created widespread sensation as well as great embarrassment for Count Bethlen and his Government. Prolonged investigations and public trials resulted in the imprisonment of Windisch-Grätz, Nádosy and others, with the complete vindication of Count Bethlen.

In the general election of Dec. 1926 Hungary showed its deepened confidence in Count Bethlen by returning him once more to power by a greatly increased majority. The combined Opposition succeeded in obtaining only 37 seats in a house of 245.

In Jan. 1927 Count Bethlen successfully concluded Hungary's first post-war political treaty. He visited Rome and signed with Signor Mussolini a Pact of Friendship, one of the most important clauses of which accorded to Hungary the use of the port of Fiume. In order to take full advantage of the facilities at Fiume it was necessary also to enter into negotiations with Yugoslavia. These were also initiated by Count Bethlen under friendly and favourable circumstances. The signing of the Italo-Hungarian Treaty was generally admitted to be a considerable political success for Count Bethlen, particularly in conjunction with the conclusion of commercial treaties with Czechoslovakia and Yugoslavia.

Count Bethlen in Nov. 1927 introduced a law for the modification of the Numerus Clausus Law by which greater opportunities were to be given in Hungarian Universities to Jewish students.

Throughout 1927 the Council of the League of Nations was occupied with the question of the powers of the Mixed Arbitral Court in relation to the compensation claims against Rumania by Hungarian optants. This case attracted world-wide attention, but as Count Bethlen was himself an optant and therefore peculiarly interested he abstained, with characteristic scrupulousness, from taking part in the discussions before the League.

By the end of 1927 Count Bethlen had been continuously in power longer than any prime minister in Europe. He married Countess Margit Bethlen, a talented poetess, and has three sons. He belongs, like his ancestors who raised armies for Calvinism, to the Reformed (Calvinist) Church. (W. Go.)

BETHMANN-HOLLWEG, THEOBALD VON (1856-1921), German statesman, was born on Nov. 29, 1856, at Hohenfinow, near Berlin. He was descended from the Frankfort banking family of Bethmann, which attained great prosperity in the 18th century, and a branch of which was founded by his great-grandfather Johann Jakob Hollweg, who had married a daughter of the house.

Having risen through the regular legal and official stages of promotion, in 1905 he was appointed Prussian Minister of the Interior and in 1907 secretary of state for the Imperial Home Office, and vice-president of the Prussian Ministry. At the time of Bethmann-Hollweg's appointment to the chancellorship in 1909, internal affairs, under his predecessor, Prince Bülow, had reached a deadlock in the *reichstag* owing to the revolt of a section of the Liberal-Conservative *bloc* against the proposal to establish death duties as part of the reform of the finances of the empire. It was not until the general elections of 1912 had transformed the situation by bringing a great accession to the strength of the moderate National Liberals and the Left, especially the Social Democrats, that the Government was able to reckon upon a more amenable majority.

In the interval Bethmann-Hollweg endeavoured to conciliate the Catholic Centre by a policy of compromise in matters which had threatened to lead to a renewal of the *Kulturkampf*, such as the denunciation of the Reformation in the Papal Encyclical of 1910 and the Catholic demand for the modification of the Jesuit law. He secured the final abrogation of this law under stress of war conditions in April 1917. Bethmann-Hollweg was likewise the sponsor of the new constitution for Alsace-Lorraine which in 1911 established the government of that territory of the empire upon the basis of popular representation in a territorial assembly and of admission, though without full State rights, to the Federal Council. He was less successful with the vexed question of the Prussian franchise, which, in 1910, he attempted to solve by proposing a direct system of election while retaining in a modified form the local division of the electorate according to income-tax assessment into three classes. His bill was ultimately rejected by the reactionary Chamber of Deputies.

He was equally unsuccessful in dealing with an outbreak of militarism in Nov. 1913 at Zabern (Saverne) in Alsace, where the population, exasperated by the truculence of a young officer, was subjected to the arbitrary exercise of martial law by the colonel in command of the garrison. Bethmann-Hollweg's treatment of the incident satisfied neither the reactionaries nor the advanced parties, and, for the first time in the history of the *reichstag*, a vote of censure was passed upon the Chancellor.

In 1914 Bethmann-Hollweg became famous by his remark to Sir Edward Goschen, British ambassador in Berlin, that the Belgian guarantee was "a scrap of paper." Over unrestricted submarine warfare he divested himself of responsibility, having declared in Jan. 1917, "I can give Your Majesty neither my assent to the unrestricted submarine warfare nor my refusal."

By the middle of July 1917, Bethmann-Hollweg had lost all support in the *reichstag*. The Conservatives and National Liberals were alienated by his Prussian franchise policy and his conflicts with the higher command. The Left and the Catholic Centre, in which Erzberger with his so-called Peace Resolution (adopted by the *reichstag* on July 19) had acquired the upper hand, were convinced that the Allied and Associated Powers would place no confidence in the overtures of men with the past

of Bethmann-Hollweg and Zimmerman. Finally, on the morrow of the publication of the second Prussian Franchise Edict, on July 14, 1917, Hindenburg and Ludendorff came to Berlin in order to hold conferences with the chiefs of political parties regarding the terms of the "Peace Resolution." The Chancellor could not tolerate this military interference with his own department, and the emperor, confronted with an ultimatum from his two indispensable military leaders, accepted the Chancellor's resignation. Bethmann-Hollweg retired to Hohenfinow and took no further part in politics beyond writing his *Reflections on the World War* (1919). He died at Hohenfinow on Jan. 1, 1921, after a brief illness.

BETHNAL GREEN, an east metropolitan borough, London, England, bounded north by Hackney, east by Poplar, south by Stepney and west by Shoreditch. Pop. (1921), 117,238. It is a district of poor houses in the "East End." The people make match-boxes, boots, furniture, textiles, metal objects, etc., but were formerly largely devoted to silk-weaving, which spread from Spitalfields (see STEPNEY). The Bethnal Green museum was opened in 1872. It contains exhibits of food and animal products, formerly at South Kensington, entomological collections, etc.; it stands in public gardens. There are other small open spaces; and some 70 out of the 217 acres of Victoria Park are within the borough. Among institutions are the missionary settlement of the Oxford House, founded in 1884, with its women's branch, St. Margaret's House; the North-Eastern hospital for children, the Craft school and the Leather Trade school. The parliamentary borough of Bethnal Green has two divisions, each returning one member. The borough council consists of a mayor, five aldermen and 30 councillors. Area, 760 acres.

BETHSAIDA: see CHORAZIN.

BÉTHUNE (FAMILY). The seigneurs of Béthune, *avoués* (*advocati*) of the great abbey of Saint-Vaast at Arras from the 11th century, were the ancestors of a great French house whence sprang the dukes of Sully, Charost, Orval, and Ancenis; the marquises of Rosny, Courville, and Chabris; the counts of Selles and the princes of Boisbelle and Henrichemont. Conon de Béthune (q.v.), the crusader and poet, was an early forbear. The most illustrious member of the Béthune family was Maximilien, baron of Rosny, and afterwards duke of Sully (q.v.), minister of Henry IV. His brother Philip, count of Selles and of Charost, was ambassador to Scotland, Rome, Savoy, and Germany, and died in 1649. Hippolyte de Béthune, count of Selles and marquis of Chabris, who died in 1665, bequeathed to the king a magnificent collection of historical documents and works of art. The Charost branch of the family gave France a number of generals during the 17th and 18th centuries.

The last duke of Charost, Armand Joseph de Béthune (1738-1800), French economist and philanthropist, served in the army during the Seven Years' War, after which he retired to his estates and sought to ameliorate the lot of his peasants by abolishing feudal dues and introducing reforms in agriculture. Louis XV. said of Charost, "Look at this man, his appearance is insignificant, but he has put new life into three of my provinces." His only son, Armand Louis de Béthune, marquis de Charost, was beheaded on April 28 1794.

BÉTHUNE, CONON or QUESNES, **DE** (c. 1150-1224), French troubadour or *trouvère* of Arras, was born in the 12th century. He came about 1180 to the court of France, where he met Marie de France, countess of Champagne. To this princess his love poems are dedicated, and much of his time was passed at her court where the *trouvères* were held in high honour. At the French court he met with some criticisms from Queen Alix, the widow of Louis VII., on the roughness of his verse and on his Picard dialect. To these criticisms, interesting as proof of the already preponderant influence of the dialect of the Île de France, the poet replied by some verses in the satirical vein that best

suited his temperament. Some of his best songs were inspired by anger at the delays before the crusade of 1188-92. Conon took part with Baldwin of Flanders in the crusade of 1204, and he is said to have been the first to plant the crusaders' standard on the walls of Constantinople. He held high office in the new empire and died about 1224. His verses, of which the crusading song *Ah! amors com dure departie* is well known, are marked by a vigour and martial spirit which distinguish them from the work of other *trouvères*.

The completest ed. of his works is in the *Trouvères belges* of Aug. Scheler (1876).

BÉTHUNE, town of France, capital of an arrondissement, department of Pas-de-Calais, 24m. N.N.W. of Arras, on the railway between Arras and St. Omer. Pop. (1926) 19,281. Béthune is situated on a low hill at the confluence of the Lawe with the canal from Aire to Bauvin. The town dates from the 11th century and was governed by its own lords till 1248, after which it passed successively to the counts of Flanders, the dukes of Burgundy, and the sovereigns of Austria and Spain. Ceded to France by the peace of Nijmegen (1678), it was taken by the allied forces in 1710, and restored to France by the treaty of Utrecht. The main front astride the La Bassée Canal was situated about 5m. from Béthune during the World War, and the town thus became an important base. During the German advance (April 1918) many of the houses and public buildings were destroyed by bombardment. Béthune lies in the midst of the richest coal mines in France. Its industries include the distillation of oil, tanning, salt-refining and the manufacture of earthenware and casks. Trade is carried on in flax, cloth, cereals, oil-seeds, etc.

The town is the seat of a sub-prefect, and has a tribunal of first instance and a chamber of commerce.

BETOYAN, an important linguistic stock of South American Indians, so called from the Betoyes, one of its important tribes. The Betoyan stock occupies an extensive area in the region drained by the north-western tributaries of the Amazon system, from the Napo river in the south, northwards to the upper Apure in south-western Venezuela, and from the eastern slopes of the Andes eastwards to approximately 70° W. long. At least 60 or 70 tribes are included in the group.

Among the Betoyan tribes in general, the men wear a small apron or breech-clout, and the women wear an apron or go naked. The labret in the lower lip is common as an ornament. In general they are a sedentary, agricultural folk, growing manioc and maize, and living in large communal houses, usually rectangular and built of thatch. Some tribes, however, use a conical circular type of dwelling. Many make considerable use of coca, and most employ one or other narcotics and narcotic snuffs, inhaled by means of V-shaped bone tubes. The bow, spear (often poisoned), sword-club and blow-gun are their most important weapons. Most tribes make use either of great wooden signal drums, hollowed out of tree trunks, or of huge trumpets or flutes. The pan-pipe is also used. Dugout canoes are used on the rivers. Pottery is made, but tree-bast takes the place of textiles. Boys are obliged to pass through a puberty ceremony, involving whipping. The dead are buried (often in a canoe for a coffin) under the floor of the house. Several tribes exhume the bones after several years, burn them, and drink the ashes mixed with corn beer. The funeral ceremonies are elaborate, and involve the use of characteristic conical, fringed bast masks which cover the wearer to the knees, and are supposed to represent supernatural beings.

Koch-Krüneberg, *Zwei Jahre unter den Indianern* (Berlin, 1909-10); H. Beuchat and P. Rivet, "La famille Betoya ou Tucano" (*Mem. Soc. Linguistique de Paris*, vols. xvii., xviii.).

BETROTHAL. Betrothal was anciently a formal ceremony which in most cases preceded the actual marriage service, usually by a period of some weeks, but the marriage might be delayed for years. The canon law distinguished two types of betrothal:—(1) *Sponsalia de praesenti*, (2) *Sponsalia de futuro*.

The first was a true though irregular marriage, and was abolished by the Council of Trent as inimical to morality. The second was a promise to marry at a future date. The church never determined the form of the ceremony, but demanded that it should be entered into freely and at a legal age. The church further declared that females between the ages of 7 and 12, and males between 7 and 14, could be betrothed, but not married. The ill-defined laws as to betrothals tended to encourage abuses, especially in the rural districts. Betrothal consisted of the "interchange of rings—the kiss—the joining of hands, to which is to be added the testimony of witnesses." In France the presence of a priest was essential, and it was customary elsewhere for the couple to get their parish priest to witness their promise. Among the peasantry the place of rings was taken by a coin which was broken between the pair, each taking a part. But almost any gift sufficed. Sometimes the bride-elect received a bent or crooked sixpence. At the conclusion of the ceremony it was usual for the couple to pledge each other in a cup of wine. Gifts given at betrothal could be recovered by the parties if the marriage did not take place. The church jealously watched over the fulfilment of such contracts and punished their violation. Betrothal, validly contracted, could be dissolved either by mutual consent or by the omission to fulfil one of the conditions of the contract. But here the church stepped in to override such law as existed by decreeing that whoever, after betrothal, refused to marry *in facie ecclesiae* was liable to excommunication. In England the law was settled by an act of 1753, which enacted that an aggrieved party could obtain redress only by an action at common law for breach of promise of marriage (see MARRIAGE).

Formal betrothal is no longer customary in England, but on the European continent it retains much of its former importance. In Germany, if the parties are under age the consent of the parents is needed; but if this be unreasonably withheld the couple may appeal to a magistrate. Public betrothal carries with it an obligation to marry, and in case of refusal an action "lies" for the injured party. Among the ancient Jews betrothal was formal and as binding as marriage.

BIBLIOGRAPHY—For betrothal customs in China, the East and elsewhere, consult L. J. Miln, *Wooings and Weddings in Many Climes* (1900) and H. N. Hutchinson, *Marriage Customs in Many Lands* (1897). On early English law as to betrothals see Sir F. Pollock and Maitland, *History of English Law before the time of Edward I.* (2nd ed 1898). See also J. O. Halliwell-Phillips, *Outlines of the Life of Shakespeare* (1848, 1883).

BETTERMENT, a term used particularly in connection with the increased value given to real property by causes for which a tenant or the public, but not the owner, is responsible. A statute passed to facilitate the rebuilding of London after the Great Fire of 1666 embodied the principle that owners of property who derived a direct pecuniary benefit from a public improvement are bound to contribute some fair proportion of the cost. A "betterment charge" is defined by Prof. Seligman as "a compulsory contribution levied in proportion to the special benefits derived to defray the cost of a specific improvement to property undertaken in the public interest." The betterment sections of the Act of Charles II. were imported almost bodily into the first statute establishing this principle passed by the city of New York in 1691, whence it spread throughout most of the Union under the name of "special assessment." From the United States it passed to Canada, Australia, New Zealand, South Africa, and to some British possessions. In England the statute of 1667 was followed by legislation of a similar character, until in 1760, by 2 Geo. 3, c. 29, the principle of betterment was abandoned. After the passing of the Municipal Reform Act 1832, the principle was revived in the Westminster Sewers Act 1834. It was recognized in the Metropolitan Sewers Act 1848; the Wimbledon and Putney Common Act 1871; the Public Health Act 1875; the Artisans Dwelling Act 1882; the Housing of the Working Classes Act 1890; the Manchester Corporation Act 1894; the London County Council (Improvements) Act 1897; the Town Planning Act 1925; the Town Planning (Scotland) Act 1925; and the Roads Improvement Act 1925.

The betterment principle has been applied also in France, Bel-

gium and Germany. (See COMPENSATION.)

See E. R. A. Seligman, *Essay in Taxation*, 8th ed. (1913); T. M. Cooley, *A Treatise on the Law of Taxation* (Chicago, 1903); V. Rosewater, *Special Assessments* (1893). (H. H. L. B.)

BETTERTON, THOMAS (c. 1635–1710), English actor, son of an under-cook to King Charles I., was born in London. He was apprenticed to John Holden, Sir William Davenant's publisher, and possibly later to a bookseller named Rhodes, who had been wardrobe-keeper to the theatre in Blackfriars. The latter obtained in 1659 a licence to set up a company of players at the Cockpit in Drury Lane, and here Betterton made his first appearance in 1660. His talents at once brought him into prominence, and he was given leading parts. On the opening of the new theatre in Lincoln's Inn Fields in 1661, Sir William Davenant, the patentee, engaged Betterton and all Rhodes's company to play in his *Siege of Rhodes*.

Betterton was held in high esteem by Charles II. who sent him to Paris to examine stage improvements there. According to Cibber it was after his return that shifting scenes instead of tapestry were first used in an English theatre. In 1692, in an unfortunate speculation, Betterton and his friend Sir Francis Watson were ruined; but Betterton's affection for Sir Francis was so strong that he adopted the latter's daughter and educated her for the stage. In 1693, with the aid of friends, he erected the New Playhouse in the tennis court in Lincoln's Inn Fields. It was opened in 1695 with Congreve's *Love for Love*. But in a few years the profits fell off, and Betterton determined to quit the stage. At his benefit performance, when the profits are said to have been over £500, he played Valentine in *Love for Love*. In 1710 he made his last appearance as Melantius in *The Maid's Tragedy*; he died on April 28, and was buried in Westminster Abbey.

In appearance he was athletic, slightly above middle height, with a tendency to stoutness; his voice was strong rather than melodious, but in recitation it was used with the greatest dexterity. Pepys, Pope, Steele and Cibber all bestow lavish praise on his acting. The blamelessness of his life was conspicuous in an age and a profession notorious for dissolute habits. Betterton was author of several adaptations which were popular in their day. In 1662 he had married Mary Saunderson (d. 1712), an admirable actress, whose Ophelia shared the honours with his Hamlet.

BIBLIOGRAPHY—*The Life and Times of Thomas Betterton* (1886); see Howe, *Thomas Betterton* (1891); Odell, *Shakespeare from Betterton to Irving* (vol. 1), (1921).

BETTINELLI, SAVERIO (1718–1808), Italian Jesuit and man of letters, was born at Mantua on July 18, 1718. He entered the Society of Jesus in 1736, taught rhetoric at Venice, and was then head of the college of nobles at Parma. He travelled extensively in Europe, and finally settled in Italy in 1759, and had just been appointed to the chair of rhetoric at Modena in 1773 when the Jesuits were banished. His old age was spent in Mantua. He had become famous with his *Lettere dieci di Virgilio Agli Arcadi* (1756), in which he attacked the cult of Dante. This book which brought him personal compliments from Voltaire, made him many enemies. His most important work is the *Risorgimento negli studj, nelle Arti e ne' Costumi dopo il Mille* (1775–86), a sketch of the progress of literature, science, the fine arts, industry, etc., in Italy.

See Federico *L'opera letteraria di Saverio Bettinelli* (1913).

BETTING TAX. By the enactment of the Finance Act, 1920, the British Parliament imposed a duty on bets and betting, thereby following the example of many countries both within and without the British empire. This means of raising revenue was recommended by a majority of the committee appointed by the House of Commons in 1923 to report on the subject, and in the Budget of 1926 the chancellor of the exchequer (Mr. Winston Churchill) made the first definite proposals for giving legislative shape to the committee's recommendations.

The scheme of the legislation is to charge excise duties on betting, and on certificates required to be taken out by bookmakers in respect of their businesses and premises. On and after Nov. 1, 1926, betting duty must be payable on every bet made with a

bookmaker, at the rate of $3\frac{1}{2}\%$ of the amount staked. In the case of a bet in respect of a horse race with a bookmaker on the course or by a person on the course, the rate of duty was 2% of the amount staked. Bookmakers must take out a "bookmaker's certificate" every year, on which an annual duty of £10 must be paid, and a similar duty is payable annually in respect of an "entry certificate," which must be taken out by a bookmaker for any betting premises kept or used by him.

The betting duty is payable by the bookmaker with whom the bet is made, who must issue to the backer at the time of making the bet a "revenue ticket" denoting that the duty has been paid. These tickets need not, however, be issued by a bookmaker who has arranged with the commissioners of inland revenue to furnish returns of all bets made with him and has given security for the payment of the duty.

Penalties are provided for contravention of the act, for carrying on business as a bookmaker without having a proper certificate in force, and for keeping or using, or assisting or being concerned in the keeping or using, of any betting premises in respect of which a proper entry certificate is not in force. Any person who is found accepting a bet without issuing a revenue ticket, or who fails to produce a bookmaker's certificate when lawfully required, may be arrested without a warrant by any officer. A court before which a bookmaker is convicted of any offence under these provisions may order him to be disqualified from holding a bookmaker's certificate for any period the court may think fit; but a bookmaker so disqualified may apply after three months for the removal of the disqualification.

Betting Not Legalized.—When these proposals were first put before Parliament they met with much opposition both from bookmakers and from persons and societies opposed to the practice of betting on religious, moral or social grounds. The bookmakers were apprehensive that the tax would diminish betting; other objections were based on the fear that betting, by being taxed, would thereby be recognized by the State as being lawful. To meet apprehensions of the latter kind, the section imposing the duty provided that nothing in the provisions was to render lawful any betting in any manner or place in which it was at the commencement of the act unlawful, or was to authorize the writing, printing, publication or sending of any notice, circular or advertisement which was at that time unlawful. Illegal betting, as in the case of street betting, therefore, remains illegal. Bets are not made recoverable at law by the payment of the duty.

In July 1927 the chancellor of the exchequer stated in the House of Commons that in the eight months to the end of June 1927 the tax had yielded about £1,750,000.

The only alteration made by the Finance Act of 1927 was the extension of the reduced duty of 2%, which in 1926 applied only to bets on horse races, to bets made on the ground on any sporting event and the Finance Act of 1928, which substituted 2% and 1% for $3\frac{1}{2}\%$ and 2%. The experience of other countries points to the expectation that the duty will yield a satisfactory return, and that improved methods of collection will be found. In most countries where such a tax is imposed, the method of collection is either by means of the totalizator or the pari mutuel.

Totalizator.—The totalizator is a machine operated by electric power, which, working on almost the same principle as a cash register, registers every bet made with it, and shows publicly the amount of money staked on each horse in the particular race, and the total amount staked on all horses in the race. The pari mutuel system, used in France, is operated on much the same lines, but by human agency. The totalizator and pari mutuel systems were legalized in Great Britain by the Racecourse Betting Act of 1928, which set up a board of control. (J. S. S.)

BETTWS-Y-COED (Bêt'tōos-î-koid), urban district, Carnarvonshire, north Wales, situated on the Llugwy, near its confluence with the Conway. Southward, above the confluence, the Vale of Conway is narrow, and in less than two miles the confluence of the Lledr from the west and the Conway from the east is reached, giving routes to Blaenau Festiniog and Corwen respectively. Population (1921) 1,025. The words *y coed* ("the wood") are added to distinguish the village from more than one other Bettws

(=Bede-house) in Wales. Since the days of David Cox the neighbourhood, with its beautiful glen and river scenery, has been famous as a centre for artists and tourists. In summer it is much visited by motor traffic from England and from the seaside resorts of north and west Wales, being well served by roads, and by the railway (London, Midland and Scottish) from Conway. It is also on one of the main approaches to Snowdonia, Telford's "Holyhead Road" crossing the Conway by an iron bridge dating from 1815. The picturesque bridge over the Llugwy in the village dates from the 15th century. Most of the streams provide trout fishing; and the Conway, where the primitive coracle has long lingered, is famous for its salmon. Other objects of interest are the Swallow falls (Rhaidr-y-Wenol) $2\frac{1}{2}$ m. from Bettws to the west and Dolwyddelan Castle, about 6 m. S.W. of Bettws-y-coed, a keep of uncertain date near a slate-quarrying village of that name, the birth-place of Llewellyn the Great (1194-1240).

BETTY, WILLIAM HENRY WEST (1791-1874), English boy actor, known as "the young Roscius," was born on Sept. 13, 1791, at Shrewsbury. He first appeared on the stage at Bel-fast before he was twelve in an English version of Voltaire's *Zaire*. He afterwards played with success in Dublin, Glasgow and Edinburgh. In 1804 he first appeared at Covent Garden, when the troops had to be called out to preserve order, so great was the crush to obtain admittance. At Drury Lane he played for the unprecedented salary of over 75 guineas a night. George III. presented him to the queen, and Pitt on one occasion adjourned the House of Commons that members might be in time for his performance. In 1808 he made his final appearance as a boy actor, and entered Christ's college, Cambridge. He reappeared four years later, but the public would have none of him. He died in 1874. His son Henry Betty (1819-97) was also an actor.

BETUL, a town and district of British India, in the Nerbudda division of the Central Provinces. Pop. (1921) 5,773. The administrative headquarters of the district were moved many years ago to the town of Badnur (*q.v.*) 3 miles to the north.

The District of Betul has an area of 3,872 square miles. Pop. (1921) 363,737. The mean elevation of the district is about 2,000 ft. It is the westernmost of the Satpura districts situated upon the elevated tract which divides the Nerbudda valley on the north from the Berar plain on the south. The northern part of the district forms an irregular plain of sandstone formation. It is well wooded and resembles an English park, but the population is sparse and the cultivation poor. The central tract possesses the best soil in the valleys of the Machna and Sampna rivers. It is well cultivated and studded with villages. In the south lies a rolling plateau of basaltic formation (with the sacred town of Multai and the springs of the river Tapti at its highest point) extending over the southern face of the district. There are basins of fertile soil enclosed between stony ridges of trap rock, and water is to be found near the surface even among the ridge lands. The richer soils produce wheat, pulse and some sugar cane, irrigated from wells; the poorer, oil seeds and small millets. The district suffered severely in the great famines of 1897 and 1900. The poorer tracts in the north are mainly inhabited by aboriginal tribes, Gonds and Korkus, but the fertile areas in the centre and south of the district are occupied by Hindu immigrants in the north from Malwa and in the south from the Deccan. Mohammedans are less than 2% of the population.

There are 1,200 square miles of Government forests exporting teak and other timber. Agriculture and forests provide the chief occupations of the people and there is no large industry. In spite of its rugged character the district has progressed. A number of roads were made in the farnies, and a few years ago the northern section of the railway Itarsi to Nagpur opened up the north of the district with a branch to the Chhindwara coalfields. The southern section into Nagpur was completed in 1926, and the districts have developed very greatly in consequence.

In olden days the district had many changes of rulers, both local and from the north and south, but it passed into the hands of the Mahrattas from the Gonds in 1743 and came under British rule in 1818. Since the British census of 1872 the population has increased from 276,000 to 364,000. In 1911 it was

390,000, but the decline of 26,000 due to the influenza epidemic (1918-19) is likely to be made up. It is one of the most peaceful districts of the Central Provinces. Its urban population is only 13,000. The climate is comparatively temperate, but the denser jungles are very malarious.

BETWA, a river of India, which rises in the native state of Bhopal in Malwa, and after a course of 360m., for the most part in a north-easterly direction, falls into the Jumna at Hamirpur. A weir is thrown across the Betwa about 15m. from Jhansi town, whence a canal 168m. long takes off irrigating some 81,000 acres; similar works have been carried out elsewhere on the river.

BETZDORF, a town in Rhenish Prussia, on the river Sieg, a tributary of the Rhine, 35m. E. of Bonn. Pop. (1925), 8,495. Iron is mined and there are machinery and wagon works.

BEUDANT, FRANÇOIS SULPICE (1787-1850), French mineralogist and geologist, was born at Paris on Sept. 5, 1787. In 1817 he published a paper on the phenomena of the crystallization of minerals. In 1818 he was sent by the French Government on a geological journey through Hungary, and his *Voyage minéralogique et géologique en Hongrie* (with atlas, 1822) established for him a European reputation. In 1820 he was appointed to the professorship of mineralogy in the Paris faculty of sciences, and afterwards became inspector-general of the university. He subsequently published treatises on physics and on mineralogy and geology, and died on Dec. 10, 1850.

BEUEL, a town on the Rhine opposite Bonn, Rhenish Prussia. Pop. (1925) 17,553. Metal-work, asphalt, basalt, cardboard, paper, vaseline and chemicals are produced.

BEULE, CHARLES ERNEST (1826-74), French archaeologist and politician, was born at Saumur on June 29 1826. As one of the professors in the École Française at Athens he had the good fortune to discover the propylaea of the Acropolis, and his work, *L'Acropole d'Athènes* (2nd ed., 1863), was published by order of the minister of public instruction. In May-Nov. 1873 he was minister of the interior in the Broglie ministry. He died by his own hand on April 4 1874. He was the author of numerous works on archaeological and historical subjects.

See Ideville, *Monsieur Beulé, Souvenirs personnels* (1874).

BEURNONVILLE, PIERRE DE RUEL, MARQUIS DE (1752-1821), French general. Minister of war in Feb. 1793, he denounced his old commander, C. F. Dumouriez, to the Convention, and was one of the four deputies sent to watch him. Given over by him to the Austrians on April 3, 1793, Beurnonville was not exchanged until Nov. 1795. He entered the service again, and was appointed inspector of infantry of the army of England in 1798. In 1800 he was sent as ambassador to Berlin, in 1802 to Madrid. Napoleon made him a senator and count of the empire. A member of the provisional government in 1814, he followed Louis XVIII. to Ghent during the Hundred Days and after the restoration was made marquis and marshal of France.

See A. Chaquet, *Les Guerres de la Révolution* (1886).

BEUST, FRIEDRICH FERDINAND VON, COUNT (1809-1886), Austrian statesman, was born January 13, 1809, in Dresden, of an ancient Brandenburg family long settled in Saxony. He was educated at Leipzig and Göttingen, and entered the Saxon diplomatic service in which he served at Berlin, Paris, Munich and London. In Feb. 1849 he became minister for foreign affairs and also minister for education and public worship, an office he exchanged in 1853 for the ministry for internal affairs, in which year he also became minister-president. His was the hand that guided Saxony through the revolutionary days of 1849 and which subsequently restored order by repressive measures that won him the hatred of the German Liberals. But his chief interest was in foreign policy, and he became the champion of the lesser German states against the hegemony, and unifying policy, of Prussia. This policy naturally brought him into conflict with Bismarck who attacked him in the press as a "particularist," or supporter of the smaller states as against Prussia. In 1851 he supported Austria and again in 1866 when Bismarck forced the Seven Weeks' War upon Austria. After Königgrätz, Bismarck refused to negotiate with him; and Beust in consequence resigned all his offices.

At the moment when his public career seemed to have ended in disaster, he received a wholly unexpected offer from the Emperor Francis Joseph of the Austro-Hungarian Ministry for Foreign Affairs. A Protestant and a Saxon might well have hesitated to accept such a post at such a moment; but Beust did not hesitate, and threw himself into his new task with all his untiring energy. He brought the negotiations for the *Ausgleich* between Austria and Hungary to a successful conclusion and, in his capacity of Austro-Hungarian minister-president, restored parliamentary government and by a liberal policy did much to rid the country of repressive and mediaeval institutions and restrictions. For his services in these and other matters, he was raised to the dignity of a count in 1868 and made chancellor of the empire. At the same time he surrendered the office of minister-president to Hohenwart whose federalist plans were subsequently a probable cause of his downfall. In foreign policy Beust did much to improve the reputation of the empire abroad, and he ever worked steadfastly to promote a Franco-Austrian *entente*. When the Franco-Prussian war broke out, Beust openly displayed his sympathy for France; but he completely accepted the resulting unification of Germany and, at the moment of his dismissal from office in 1871, was engaged in promoting a good understanding between the Central empires.

The exact reason for his dismissal has never been divulged (it is said Beust himself never learnt of it), but his downfall was softened by his appointment as Austrian ambassador at London from whence he was transferred to Paris in 1878. He retired from the diplomatic service in 1882, and died at Altenberg, near Vienna, on Oct. 24, 1886.

A diplomatist *à la carrière*, a wit and man of the world, Beust has hitherto been dismissed too lightly as a statesman of the makeshift school. The recent opening to public inspection of the Austrian archives has enabled the full details of his diplomacy to be studied; and from such a study Beust emerges with an enhanced reputation. His sangfroid in moments of crisis was wholly admirable, because it was not the sangfroid of one who did not appreciate the dangers by which he was beset. If he was more German than Hungarian in his outlook on affairs that mutually concerned the two races, he can scarcely be blamed; and certainly at all times he sought to tread along a middle course of safety in foreign policy and firm and equitable government at home.

BIBLIOGRAPHY.—Beust was the author of reminiscences: *Aus drei Viertel-Jahrhunderten* (Stuttgart, 1887; English trans. edited by Baron H. de Worms); he also wrote a shorter work, *Erinnerungen zu Erinnerungen* (Leipzig, 1881), in answer to attacks made on him by his former colleague, Herr v. Friesen, in his reminiscences. See also Ebeling, *F. F. Graf v. Beust* (Leipzig, 1876), a full and careful account of his political career, especially up to 1866, *Diplomatic Sketches*: No. 1, *Count Beust*, by Outsider (Baron Carl v. Malortie); Flathe, *Geschichte von Sachsen*, vol. iii. (Gotha, 1877); Friesen, *Erinnerungen aus meinem Leben* (Dresden, 1880); L. Eisenmann, *Le Compteur austro-hongrois de 1867* (1904); E. von Wertheimer, *Andrassy* (1910). (I. F. D. M.)

BEUTHEN, a town of Germany, in the extreme south-east of the Prussian province of Upper Silesia, 120m S.E. of Breslau, on the railway to Cracow. Pop. (1925), 62,643. It is the centre of the mining district (lead and zinc) of Upper Silesia. Arising out of this are its chemical and machine industries. Beuthen is an old town, and was formerly the capital of the Bohemian duchy of Beuthen, which in 1620 was ultimately granted, as a free lordship of the empire, to Lazarus, Baron Henckel von Donnersmarck, by the emperor Ferdinand II. In the partition of Upper Silesia between Germany and Poland in 1921 (see SILESIA) Beuthen was retained by Germany.

BEVEL, the inclination of one surface of a solid body to another, also any angle other than a right angle, and in carpentry or joinery the angle to which a piece of timber must be cut. The tool known as a bevel is a rule with two arms that can be set at any angle. In heraldry, a bevel is an angular break in a line. Bevelment or bevelling is a term in crystallography expressing the replacement of the edge of a crystal by two planes equally inclined to the planes adjacent to them. In architecture, a bevel is any sloped edge, or the surface resulting when the corner of a

beam or other member is cut off at an angle. The term bevel is used especially when the resultant surfaces are relatively small; the term splay is used when they are large. Bevel is used also to describe the sloped surfaces between the projecting faces and the recessed joints of rusticated masonry.

BEVERLEY, WILLIAM ROXBY (1814?–1889), English artist and scene-painter, was appointed scenic director for the Covent Garden operas in 1853. In 1854 he entered the service of the Drury Lane theatre and for 30 years continued to produce wonderful scenes for the pantomimes, besides working for Covent Garden and a number of other theatres. He executed many dioramic views, and was a frequent exhibitor of sea pictures at the Royal Academy from 1865 to 1880. He died at Hampstead on May 17, 1889.

BEVERLEY, municipal borough in the East Riding of Yorkshire, England, eight m. N.N.W. of Hull on a branch of the L.N.E.R. Population (1921) 13,469. It lies in a level country east of the Yorkshire Wolds, near the river Hull, and has communication by canal with Hull. There are evidences of a pre-Conquest. A traditional charter of 925 is said to have granted sanctuary in the town. Thurstan, archbishop of York, gave the burgesses their first charter in the reign of Henry I. The church of St. John the Evangelist, Beverley minster, is on the site of a Saxon church founded by John of Beverley (640–721), which became a college of secular canons in the 10th century. It shows some of the finest examples of Early English architecture in the country, while the west front and most of the exterior is in the Decorated style. The church of St. Mary also shows beautiful Decorated and Perpendicular work. Of the old walls of the town only a 15th century gateway remains. Cloth weaving, one of the chief mediaeval industries of Beverley, was important as early as 1315. Beverley was a large market centre, especially from Tudor times, and in 1534–55 was granted three fairs together with weekly markets on Wednesdays and Saturdays. Incorporation charters were granted in 1573, 1629, 1663 and 1685. In the 18th and 19th centuries a large agricultural trade grew up and the town became the social centre of the neighbourhood. Subsidiary industries include tanning, brewing and the manufacture of chemicals. Beverley has been largely superseded by Hull. The municipal borough has an area of 2,404 ac. and is the seat of a suffragan bishop in the diocese of York. Beverley is in the Holderness parliamentary division.

BEVERLY, a city of Essex county, Massachusetts, U.S.A., on the picturesque "North Shore," opposite Marblehead, and 18 m. N.E. of Boston. It has a land area of 15 sq. m., includes nine miles of seacoast, and is the starting point of the famous North Shore drive, which winds past the beautiful summer resorts of Pride's Crossing and Beverly Farms (within the city limits), Manchester and Magnolia, and on to Gloucester and the towns on Cape Ann. It is served by the Boston and Maine railway, motor buses, and steamers. The population was 13,884 in 1900; 22,685 in 1925; and over 27,000 in 1927, according to local survey.

Manufacturing and commerce have displaced the fishing and seafaring occupations of earlier days; and among the manufactures shoe-machinery has taken the place formerly held by boots and shoes, which are still, however, an important product. The plant of the United Shoe Machinery Corporation has 21 ac. of floor space and 6 m. of aisles. In all some 35 products are manufactured in the city, including oiled clothing, shoe findings, soles, heels, lasts and counters. The output of the 44 establishments in 1925 was valued at \$11,803,325. Beverly is an important receiving and distributing point for oil from the Texas fields and for coal. The commerce of the harbour in 1925 amounted to 306,476 tons, chiefly of these two commodities, and was valued at \$5,830,233. Market-gardening and horticulture are carried on quite extensively within the city. The assessed valuation of property is about \$55,000,000, giving a per capita valuation second highest among the cities of the State.

Beverly was settled in 1626 by Roger Conant; was incorporated as a separate township in 1668, and as a city in 1804. The first cotton-mill in the United States was established here in 1788, and the manufacture of Britannia ware was begun in 1812.

It was the home of George Cabot (1751–1823), Nathan Dane (1752–1835), and Wilson Flagg (1805–1884); and the birth-place of Lucy Larcom (1826–1893), who made it the scene of much of her *Story of a New England Girlhood*. During the administration of President Taft it was the summer capital.

BEVERLY HILLS, a luxurious residential city of Los Angeles county, Calif., U.S.A., adjoining Los Angeles, and 9 m. from the ocean. It was incorporated in 1914 as a city of the sixth class, and is governed by a board of trustees. The area is 4.87 square miles. The city was laid out in advance, with wide parkways and curving boulevards planted with palms and other trees, and its entire development is under control. Business is restricted to a limited central district. In 1920 the population was 674. At the end of 1927 it was estimated at 11,000; there were 2,500 registered voters; and the assessed valuation of property was over \$50,000,000.

BEVIS OF HAMPTON, the name of an English metrical romance. The wife of Guy, count of Hampton (Southampton) asks a former suitor, Doon or Devoun, emperor of Almaïne (Ger-

AFTER A WOOD CUT OF 1867
BEVIS OF HAMPTON. THE HERO OF
MANY EARLY ENGLISH ROMANCES

many), to send an army to murder Guy in the forest. The plot is successful, and she marries Doon. When threatened with future vengeance by her ten-year-old son, Bevis, she determines to make away with him also, but he is saved from death by a faithful tutor, is sold to heathen pirates, and reaches the court of King Hermin, whose realm is variously placed in Egypt and Armenia. The exploits of Bevis, his love for the king's daughter Josiane, his mission to King Bradmond of Damascus with a sealed letter demanding his own death, his imprisonment, his final vengeance on his stepfather are related in detail. After succeeding to his inheritance he is, however, driven into exile and separated from Josiane, to whom he is reunited only after each of them has contracted, in form only, a second union. The story also relates the hero's death and the fortunes of his two sons.

The oldest extant version appears to be *Boeve de Haumtone*, an Anglo-Norman text which dates from the first half of the 13th century. The oldest ms. of the English metrical romance, *Sir Beues of Hamtoun*, dates from the beginning of the 14th century. The French *chanson de geste*, *Beuve d'Hamstone*, was followed by numerous prose versions, and in Italy, where *Bovo d'Antona* was the subject of more than one poem, the tale was interpolated in the *Real di Francia*, the Italian compilation of Carolingian legend. Although the English version that we possess is based on a French original, it seems probable that the legend took shape on English soil in the 10th century, and that it originated with the Danish invaders. R. Zenker (*Boeve-Amlethus*, Berlin and Leipzig, 1904) establishes a close parallel between Bevis and the Hamlet legend as related by Saxo Grammaticus in the *Historia Danica*.

BIBLIOGRAPHY.—*The Romance of Sir Beues of Hamtoun*, edit. from six mss. and the ed. (without date) of Richard Pynson, by E. Kölbing (Early Eng. Text Soc., 1885–86–94); A. Stimming, "Der anglonormannische Boeve de Haumtone," in H. Suchier's *Bibl. Norm.* vol. vii (Halle, 1899); the Welsh version, with a translation, is given by R. Williams, *Selections of the Hengwrt MSS.* (vol. ii., 1892); the old Norse version by G. Cederschiöld, *Fornsögur Sudhrlanda* (Lund, 1884); A. Wesselofsky, "Zum russischen Bovo d'Antona" (in *Archiv für slav. Phil.* vol. viii., 1885); for the early printed editions of the romance in English, French and Italian see G. Brunet, *Manuel du libraire*, s.vv. Bevis, Beufues and Buovo.

BEWDLEY, municipal borough, Worcestershire, England, lies near the Shropshire border on the sloping right bank of the Severn. The ancient Forest of Wyre, extending from south-east Shropshire, borders the town on the west. Population (1921) 2,758. Bewdley (i.e., *Beaulieu*) was held by the king at the time of the Domesday survey. The manor, then called *Bellus Locus* or *Beaulieu* on account of its beautiful situation, was after-

wards granted to the Mortimers, in whose family it continued until merged in the Crown on the accession of Edward IV.

In 1250 a bridge, the only one between it and Worcester, was built across the river and helped the commerce of the town. Trade flowed along two routes; the Severn giving connections, through a flourishing barge-traffic with Shrewsbury, Bridgnorth, Worcester, Gloucester and Bristol; while the bridge was the crossing place of a famous west-to-east route from Ludlow, along which wool from the Welsh hills was taken to the east of England. Bewdley received its first charter from Edward IV. in 1472, and later ones in 1605, 1685 and 1708. A fair and weekly markets were granted in 1373 and confirmed at various times. At Bewdley the Worcester-Shrewsbury line of the G.W.R. is joined by lines east from Birmingham and west from Tenbury. A bridge by Telford (1797) crosses the river, while above the town an aqueduct carries the pipe from the Elan valley reservoirs in Radnorshire, to Birmingham. Bewdley serves in modern times as a market town and as a riverside pleasure resort for the Black Country. The borough is governed by a Mayor, four aldermen and 12 councillors. Area 2,105 acres. It is in the Bewdley parliamentary division of Worcestershire.

BEWICK, THOMAS (1753–1828), English wood-engraver, born at Cherryburn, near Newcastle-on-Tyne, on Aug. 12, 1753, showed, at a very early age, a remarkable talent for drawing. He had no tuition, and no models save natural objects. At 14 he was apprenticed to Mr. Beilby, an engraver in Newcastle. He seems after this to have devoted himself entirely to engraving on wood. In 1784 appeared his *Select Fables*. The *Quadrupeds* appeared in 1790. While working on the *Quadrupeds* Bewick engraved the large block known as the "Chillingham Bull." His great achievement, that with which his name is inseparably associated, the *British Birds*, was published from 1797–1804. Of his other productions the engravings for Goldsmith's *Traveller* and *Deserted Village*, for Parnell's *Hermit*, for Somerville's *Chase*, and for the collection of *Fables of Aesop and Others*, may be specially mentioned. Bewick was for many years in partnership with his former master. He died at Gateshead on Nov. 8, 1828.

See his autobiography, *Memoirs of Thomas Bewick, by Himself* (1862); D. C. Thomson, *Life and Works of Bewick* (1882); Austin Dobson, *Thomas Bewick and his Pupils* (1884), and the same author's article in the *Dictionary of National Biography*.

BEXHILL or **BEXHILL-ON-SEA**, a municipal borough and watering-place, Sussex, England, 62 m. S.E. by S. of London, on the Southern railway. Pop. (1891) 5,206; (1921) 20,363. The ancient village, with the Norman and Early English church of St. Peter, lies inland on the slope of the low hills fringing the coast. Bexhill has developed very rapidly since about 1884. It has a marine parade, pier, and kursaal, while the climate is bracing and the neighbouring country pleasant. It was incorporated in 1902, with a mayor, six aldermen and 18 councillors. Area 7,993 acres. For purposes of parliamentary representation it is included in the Rye division of Sussex.

BEXLEY, NICHOLAS VANSITTART, 1ST BARON (1706–1851), English politician, was the fifth son of Henry Vansittart (d. 1770), governor of Bengal, and was born in London on April 29, 1766. Educated at Christ Church, Oxford, he took his degree in 1787, and was called to the bar at Lincoln's Inn in 1791. He began his public career by writing pamphlets in defence of the administration of William Pitt, especially on its financial side, and in May 1796 entered parliament. In 1801 he was appointed joint secretary to the treasury, a position which he retained until the resignation of Addington's ministry in April 1804. He became secretary for Ireland under Pitt (Jan.–Sept. 1805); and secretary to the treasury (1806–07) under the Grenville administration. During these and the next few years Vansittart's reputation as a financier was gradually rising. In 1809 he proposed and carried without opposition in the House of Commons 38 resolutions on financial questions, and only his loyalty to Sidmouth prevented him from joining the cabinet of Spencer Perceval as chancellor of the exchequer in Oct. 1809. He opposed an early resumption of cash payments in 1811, and became chancellor of the exchequer when the earl of Liverpool succeeded Perceval in May 1812.

When Vansittart became chancellor of the exchequer the country was burdened with heavy taxation and an enormous debt. Nevertheless, the continuance of the war compelled him to increase the custom duties and other taxes, and in 1813 he introduced a complicated scheme for dealing with the sinking fund. In 1816, after the conclusion of peace, a large decrease in taxation was generally desired, and there was a loud outcry when the chancellor proposed only to reduce, not to abolish, the property or income tax. The abolition of this tax, however, was carried in parliament, and Vansittart was also obliged to remit the extra tax on malt, meeting a large deficiency principally by borrowing. He devoted considerable attention to effecting real or supposed economies with regard to the national debt. He carried an elaborate scheme for handing over the payment of naval and military pensions to contractors, who would be paid a fixed annual sum for 45 years; but no one was found willing to undertake this contract, although a modified plan on the same lines was afterwards adopted. Vansittart became very unpopular in the country, and he resigned his office in Dec. 1822. His system of finance was severely criticized by Huskisson, Tierney, Brougham, Hume and Ricardo. On his resignation Liverpool offered Vansittart the post of chancellor of the duchy of Lancaster. Accepting this offer in Feb. 1823 he was created Baron Bexley in March, and granted a pension of £3,000 a year. He resigned in Jan. 1828. In the House of Lords Bexley took very little part in public business, although he introduced the Spitalfields weavers bill in 1823, and voted for the removal of Roman Catholic disabilities in 1824. He took a good deal of interest in the British and Foreign Bible Mission, the Church Missionary Society and kindred bodies, and assisted to found King's college, London. He died at Fooks Cray, Kent, on Feb. 8, 1851. There are nine volumes of Vansittart's papers in the British Museum.

See S. C. Buxton, *Finance and Politics* (1888); Spencer Walpole, *History of England* (1890).

BEXLEY, urban district, Kent, England, 12m S.E. by E. of London by the Southern railway. Pop. (1921) 21,457. Bexley is mentioned in Domesday Book and has had a church since the 9th century. The present church of St. Mary is Early English and later. With the rental of the manor of Bexley, William Camden, the antiquary, founded the ancient history professorship at Oxford. The course of Watling Street may be traced over Bexley Heath. Agriculture is still important, but the industrialization of the region during the present century has greatly increased the population (12,918 in 1901). Metal workers, including fitters, engineers and tool makers, are the most important elements in the population. Chemical industries are also carried on.

BEY, a modern Turkish word, the older form being *beg* (cf. Pers. *baig*), the administrator of a district, later an honorific title throughout the Turkish empire. In Tunis "bey" has become the hereditary title of the reigning sovereigns (see TUNISIA).

BEYBAZAR, the chief town of a *kaza* of the Angora vilayet of Turkey, situated on an affluent of the Sakaria (anc. *Sangarius*), about 52m. west of Angora. It corresponds to the anc. Lagania, renamed Anastasiopolis under the emperor Anastasius (491–518), a bishopric by the 5th century. Its well built wooden houses cover the slopes of three hills at the mouth of a gorge filled with fruit gardens and vineyards. The chief products are rice, cotton and fruits. From Beybazar come the fine pears sold in Constantinople as "Angora pears"; its musk-melons are equally esteemed; its grapes are used only for a sweetmeat called *jevizli-sujuk* ("nutty fruit sausage"). There are few remains of antiquity apart from numerous rock-cut chambers lining the banks of the stream. Pop. (1927). 21,340.

BEYERS, CHRISTIAN FREDERICK (1860–1914), South African soldier, was born in the Cape Colony, but went in early life to the Transvaal. He took a prominent part in the South African War, reaching the rank of general. On the grant of responsible government to the Transvaal in 1906, Beyers was elected Speaker of the House of Assembly, and commended himself to the Opposition by his tolerance and impartial conduct in the chair. On the establishment of Union, in 1910, he was ap-

pointed commandant-general of the South African Defence Force and in that capacity visited England in 1912. On the outbreak of the World War, he showed determined opposition to the policy of Botha and Smuts, especially in regard to the campaign in German South-West Africa. His ultra-patriotic views and strong religious feelings gave him much influence with the backveld Boers, and helped to foment the rebellion. After conducting an acrimonious correspondence with Smuts, he resigned his post and shortly afterwards went openly into revolt. After various vicissitudes his forces were harried and broken, and Beyers himself, in trying to escape across the Vaal river, was drowned Dec. 8 1914. At first some doubts were entertained as to the manner of his death, but on Dec. 10 these were dispelled by the finding of his body.

BEYLE, HENRI MARIE: see STENDHAL.

BEYRICH, HEINRICH ERNST VON (1815-1896), German geologist, was born at Berlin on Aug. 31, 1815, and educated at Berlin and Bonn. In 1865 he became professor of geology and palaeontology in the Berlin university; and when the Prussian Geological Survey was instituted in 1873 he was appointed co-director with Wilhelm Hauchecorne (1828-1900). He published *Beiträge zur Kenntniss der Versteinerungen des rheinischen Übergangsgebirges* (1837); *Über einige böhmische Trilobiten* (1845); *Die Conchylien des norddeutschen Tertiärgebirges* (1853-57). He died on July 9, 1896.

BEYSCHLAG, WILLIBALD (1823-1900), German Protestant divine, was born at Frankfort-on-Main on Sept. 5, 1823, and died at Halle on Nov. 25, 1900. He became professor ordinarius of practical theology at Halle in 1860. A theologian of the mediating school, he became leader of the *Mittelpartei*, and with Albrecht Wolters founded as its organ the *Deutsche evangelische Blätter*. Among his works are *Die Christologie des Neuen Testaments* (1866), *Der Altkatholicismus* (three editions, 1882-83), *Leben Jesu* (1885; 3rd ed. 1893), *Neutestamentliche Theologie* (1891-92; 2nd ed., 1896), *Christenlehre auf Grund des kleinen luth. Katechismus* (1900), and an autobiography *Aus meinem Leben* (1896-98).

See P. Schaff, *Living Divines* (1887); Lichtenberger, *Hist. Germ. Theol.* (1889); Calwer-Zeller, *Kirchenlexikon*.

BEZA (DE BÈSZE), THEODORE (1519-1605), French theologian, son of *bailli* Pierre de Bèze, was born at Vezelay, Burgundy, on June 24, 1519, of good parents, known for generous piety. An uncle, Nicolas de Bèze, counsellor of the Paris parlement, placed him (1529) under Melchior Wolmar at Orleans, and later at Bourges Wolmar, who had taught Calvin Greek, grounded Beza in Scripture. Beza studied law at Orleans (May 1535 to Aug. 1539), beginning to practise it in Paris (1539). To this period belong his exercises in Latin verse, in the loose style of the day, published by him as *Juvenilia* in 1548. Though not in orders, he held two benefices. A severe illness wrought a change in him; he married his mistress, Claude Desnoz, and joined Calvin at Geneva (Oct. 1548). In Nov. 1549 he became Greek professor at Lausanne, where he acted as Calvin's adjutant and defended the burning of Servetus in his *De Haereticis a civili magistratu puniendis* (1554). In 1558 he became professor at Geneva. His ability was shown in the Colloquy of Poissy (1561). On Calvin's death (1564), he became his biographer and successor. As a historian, Beza has been the source of serious mistakes; as an administrator, he softened the rigour of Calvin. His editions and Latin versions of the New Testament had an influence on the English versions of Geneva (1557 and 1560) and London (1611). The famous codex D. was presented by him (1581) to Cambridge university with a dubious account of the history of the ms. His numerous works are of little moment, except those mentioned. He resigned his offices in 1600, and died on Oct. 13, 1605. He was not the author of the *Histoire ecclésiastique* (1580), sometimes ascribed to him; nor, probably, of the vulgar skit published under the name of Benedict Panavantius (1551) and there is no authority for attributing it to him.

See Laingaeus, *De Vita et Moribus* (1585, calumnious); Antoine la Faye, *De Vita et Obitu* (1606, eulogistic); Schlosser, *Leben* (1806); Baum, *Th. Beza*, portrait (1843-1851); Heppé, *Leben* (1861).

BEZANT or BYZANT, a Byzantine gold coin which had a wide circulation throughout Europe up to about 1250. Its average value was about nine shillings. Bezants were also issued in Flanders and Spain. Silver bezants, in value from one to two shillings, were in circulation in England in the 13th and 14th centuries. In Wycliffe's translation of the Bible he uses the word for a "talent" (e.g., in Luke xv. 8). In heraldry, bezants are represented by gold circles on the shield, and were introduced by the crusaders.

BEZANTÉE, SHOWING THE USE OF THE DISC LIKE FORMS AS A DECORATION FOR A ROMANESQUE PIER AND ARCADE

BEZANTÉE, in architecture, a name given to a band or moulding decorated with a series of flat, circular projections supposedly resembling the coins (bezants) struck in Byzantium.

BEZBORODKO, ALEXANDER ANDREYEVICH, PRINCE (1747-1799), grand chancellor of Russia, was born at Gluchova on March 14, 1747, and educated at home and in the clerical academy at Kiev. He accompanied Count Rumyantsev, then the governor-general of Little Russia, to the Turkish War in 1768, and was present at the engagements of Larga and Kaluga, and at the storming of Silistria. The field mar-

shal recommended him to Catherine II., and she appointed him in 1775 her petition-secretary. In 1780 he accompanied her on her journey through White Russia. On his return from a delicate mission to Copenhagen, he presented to the empress "a memorial on political affairs" which comprised the first plan of a partition of Turkey between Russia and Austria. This document was transmitted almost word for word to Vienna as the Russian proposals. He followed this up by *Epitomised Historical Information concerning Moldavia*. For these two state papers he was rewarded with the posts of "plenipotentiary for all negotiations" in the foreign office and postmaster-general. From this time he was inseparably associated with Catherine in all important diplomatic affairs, though officially he was the subordinate of the vice-chancellor, Count Alexander Osterman. He wrote all the most important despatches to the Russian ministers abroad, concluded and subscribed all treaties, and performed all the functions of a secretary of state. He identified himself entirely with Catherine's political ideas, even with that of re-establishing the Greek empire under her grandson Constantine. For the foreign policy which he carried out see CATHERINE II. The empress, as usual, richly rewarded her *comes* with pensions and principalities. In 1786 he was promoted to the senate, and it was through him that the empress communicated her will to that august state-decoration. In 1787 he accompanied Catherine on her triumphal progress through South Russia in the capacity of minister of foreign affairs. On his return from concluding the peace of Jassy (1792) he found his confidential post of secretary of petitions occupied by the empress's last favourite, P. A. Zubov. He complained of this "diminution of his dignity" to the empress in a private memorial in the course of 1793. Subsequently Catherine reconciled him with Zubov, and he resumed the conduct of foreign affairs.

On the death of Catherine, the emperor Paul entrusted Bezborodko with the examination of the late empress's private papers, and shortly afterwards made him a prince of the Russian empire, with a correspondingly splendid apanage. On the retirement of Osterman he received the highest dignity in the Russian empire—that of imperial chancellor. Bezborodko was the only Russian minister who retained the favour of Paul to the last. During the last two years of his life the control of Russia's diplomacy was entirely in his hands. His programme at this period was peace with all the European powers, revolutionary France included. But the emperor's growing aversion from this pacific policy induced the astute old minister to attempt to "seek safety in moral and physical repose." Paul, however, refused to accept his resignation. He died at St. Petersburg on April 6, 1799. Bezborodko was a typical Catherinian, corrupt, licentious and self-seeking. But he was generous and affectionate.

See *Sbornik* (Collections) of the Imperial Russian Historical Society (Fr. and Russ.), vols. 60-100 (St. Petersburg, 1870-1904); Nikolai Ivanovich Grigorovich, *The Chancellor A. A. Bezborodko in Connexion with the Events of His Time* (Russ., St. Petersburg, 1879-81).

BEZEL, a sloping edge, as of a cutting tool, also known as basil. In jewellery, the term is used for the oblique sides or faces of a gem; the rim which secures the crystal of a watch in position or a jewel in its setting, and particularly the enlarged part of a ring on which the device is engraved (see RING).

BEZIERS, town of France, capital of an arrondissement, department of Hérault, 47m. S.W. of Montpellier by rail. Pop. (1926) 65,654. Béziers lies in a wine-growing district, on a hill on the left bank of the Orb, joined at this point by the Canal du Midi. The Romans established a colony here. The name Besara occurs as early as Festus Avienus (later 4th century). The town was destroyed with a great massacre in 1209 by de Montfort in the crusade against the Albigenses. The walls were rebuilt in 1289; but the town suffered severely in the wars of the 16th century, and all its fortifications were destroyed in 1632. The Allée Paul Riquet divides the old town on the west from the new town on the east. Above the old ramparts towers St. Nizaire, the former cathedral (12th to 14th centuries), a good specimen of the ecclesiastical fortification common in southern France. It has a rose window in the western façade, and stained glass and iron grilles in the choir-windows (14th century). Adjoining the south transept there are Gothic cloisters of the 14th century. There are also remains of a Roman arena. Road, canal and railway cross the Orb at Béziers. It is a market for wine, brandy, manure, chemical products, grain and flour. Béziers is the seat of a sub-prefect and has tribunals of first instance and of commerce, and several learned societies.

BÉZIQUE, a game at cards played with two similar packs from which the twos, threes, fours, fives, and sixes have been rejected, shuffled together and used as one (probably from Span *besico*, little kiss, in allusion to the meeting of the queen and knave, an important feature in the game). It is modelled on a group of card games which possess many features in common; the oldest of these is *mariage*, then follow *brusquemille*, *l'homme de brou*, *briscan* or *brisque*, and *cinq-cents*. Bézique (also *besi* and *besique*) is, in fact, *brisque* played with a double pack, and with certain modifications rendered necessary by the introduction of additional cards. The cards rank as follows.—Ace, ten, king, queen, knave, nine, eight, seven.

The usual game is for two players. The players cut for deal, and the higher bézique card deals. The objects of the play are: (1) to promote in the hand various combinations of cards, which, when declared, entitle the holder to certain scores; (2) to win aces and tens, known as "brisques"; (3) to win the so-called last trick. The dealer deals eight cards to each, first three, then two, and again three. The top card of those remaining (called the "stock") is turned up for trumps. As sometimes played, the first marriage, or the first sequence, decides the trump suit; there is then no score for the seven of trumps (see below). The stock is placed face downwards between the players and slightly spread. The non-dealer leads any card, and the dealer plays to it, but need not follow suit or win the trick. If he wins the trick by playing a higher card of the same suit led, or a trump, the lead falls to him. In case of ties the leader wins. Whoever wins the trick leads to the next; but before playing again each player takes a card from the stock and adds it to his hand, the winner of the trick taking the top card. This alternate playing and drawing a card continues until the stock (including the trump card or card exchanged for it, which is taken up last) is exhausted. The tricks remain face upward on the table, but must not be searched during the play of the hand.

The scores are shown as follows:—

Table of Bézique Scores.

Seven of trumps, turned up, dealer marks	10
Seven of trumps, declared (see below) or exchanged, player marks	10
Marriage (king and queen of any suit) declared	20
Royal marriage (king and queen of trumps) declared	40
Bézique (queen of spades and knave of diamonds) declared	40

Double bézique (all the four bézique cards) declared	500
Four aces (any four, whether duplicates or not) declared	100
Four kings (any four) declared	80
Four queens (any four) declared	60
Four knaves (any four) declared	40
Sequence (ace, ten, king, queen, knave of trumps) declared	250
Aces and tens, in tricks, the winner for each one marks	10
Last trick of all (as sometimes played, the last trick before the stock is exhausted) the winner marks	10

A "declaration" can only be made by the winner of a trick immediately after he has won it, and before he draws from the stock. It is effected by placing the declared cards (one of which at least must not have been declared before) face upwards on the table, where they are left, unless they are played, as they may be. A player is not bound to declare. A card led or played cannot be declared. More than one declaration may be made at a time, provided no card of one combination forms part of another that is declared with it. Thus four knaves and a marriage may be declared at the same time; but a player cannot declare king and queen of spades and knave of diamonds together to score marriage and bézique. He must first declare one combination, say bézique; and when he wins another trick he can score marriage by declaring the king. A declaration cannot be made of cards that have already been declared. Thus, if four knaves (one being a bézique knave) and four queens (one being a bézique queen) have been declared, the knave and queen already declared cannot be declared again as bézique. To score all the combinations with these cards, after the knaves are declared and another trick won, bézique must next be made, after which, on winning another trick, the three queens can be added and four queens scored. Lastly, a card once declared can only be used again in declaring in combinations of a different class. For example: the bézique queen can be declared in bézique, marriage, and four queens; but having once been declared in single bézique, she cannot form part of another single bézique. Two declarations may, in a sense, be made to a trick, but only one can be scored at the time. Thus with four kings declared, including the king of spades, bézique can be declared and scored, but the spade marriage cannot be scored till the holder wins another trick. The correct formula is "Forty, an 120 to score." The seven of trumps may be either declared or exchanged for the turn-up after winning a trick, and before drawing. When exchanged, the turn-up is taken into the player's hand, and the seven put in its place. The second seven can, of course, be declared. A seven when declared is not left on the table, but is simply shown.

The winner of the last trick can declare anything hitherto undeclared in his hand. After this all declarations cease. The winner of the last trick takes the last card of the stock, and the loser the turn-up card (or seven exchanged for it). All cards on the table, that have been declared and not played, are taken up by their owners. The last eight tricks are then played, but the second player must follow suit if able, and must win the trick if able. Finally, each player counts his tricks for the aces and tens they may contain, unless (as is often done) they are scored at the time. If a player revokes in the last eight tricks, or does not win the card led, if able, the last eight tricks belong to his adversary. The deal then passes on alternately until the game (1,000) is won. If the loser does not make 500, his opponent counts a double game, or double points, according as they have agreed. The score is best kept by means of a special bézique-marker.

Rubicon Bézique.—Four packs are used. Nine cards are dealt by threes to each player. The rules of ordinary bézique hold good in regard to dealing, leading, playing to lead, drawing, and declaring; but a player who receives a hand containing no picture-card (king, queen, or knave) scores 50 for *carte blanche*, which he shows. If he does not draw a picture-card, he can again score for *carte blanche*. The trump suit is decided by the first sequence or marriage declared. As four packs are used, triple and quadruple bézique may be made. Triple bézique counts 1,500, quadruple 4,500. Tricks are left face upwards, till a *brisque* (ace or ten) is played, when the winner takes all the played cards and puts them in a heap; their only value is the value of the *brisques*,

which are only counted when the scores are very close; then they are used to decide the game. They may be counted during the play, provided there are not more than 12 cards in the stock. Declarations can only be made after winning a trick and before drawing. In addition to the ordinary bézique declarations, sequence, counting 150, can be made in plain suits. Declared cards, except *carte blanche*, remain on the table. If the holder of *carte blanche* holds four aces and wins the first trick, he can declare his aces. With the exceptions already made, the scores for declarations are the same as at ordinary bézique. Declaration is not compulsory. Cards led or played cannot be declared. There are three classes of declarations, their order being (1) marriage and sequence, (2) bézique, (3) fours. A card once declared can be used for a second declaration, but only in an equal or superior class. If a card of a declared combination be played to a trick, another card of the same rank may be used to form a second similar combination; e.g., if aces be declared and one of them be played by the playing of a fifth ace, then aces can be declared a second time.

If a player has a chance of a double declaration he can declare both, but can only score one at the time. As in other variations of bézique he announces, say, "40, and 20 to score." He should repeat, "20 to score," after every trick, until he can legally score it, but if he plays a card of the combination he cannot score the points. To the last nine tricks, after the stock is exhausted, the second player must follow suit and win the trick by trumping or over-playing, if it is possible for him to do so. The winner of the odd trick scores 50.

The game consists of one deal. In reckoning the score all fractions of 100 are neglected; the winner scores 500 for game in addition to the difference between his own points and his opponent's. The loser is "rubiconed" if he does not score 1,000 points, in which case the winner adds the loser's points to his own, takes 300 for *brisques* and 1,000 for game; but the loser may claim his *brisques* to save a rubicon, though they are not reckoned among his points. If a rubiconed player has scored less than 100 the opponent counts the score as 100.

Six Pack Bézique is the most common form of rubicon bézique. It is played a great deal at London clubs, and is the most popular of modern two-handed games.

Six packs of 32 cards, each, from ace to seven, are used. The cards rank as follows—ace, ten, king, queen, knave, nine, eight, seven.

Twelve cards are dealt to each player, one at a time. If a player has a hand dealt to him without a king, queen, or knave, he declares *carte blanche* before playing a card. *Carte blanche* must be shown by exposing all the cards one at a time, and picking them up again. A player holding *carte blanche* scores 250 points, and he can go on scoring 250 points every time that he draws another plain card on showing the card drawn to his adversary.

A player is not obliged to follow suit or to trump, until the final play.

The suit of the first marriage which is declared becomes the trump suit. If a sequence is declared before any marriage the suit of the sequence is the trump suit.

The declarations and their values are as follows:—

	Points
Carte blanche	250
Royal marriage (in trumps)	40
Common marriage (in other suits)	20
Sequence (ace, ten, king, queen, knave of trumps)	250
Backdoor sequence (not in trumps)	150
Bézique (queen of spades and knave of diamonds)	40
Double bézique (two of each)	500
Treble bézique (three of each)	1500
Quadruple bézique (known as the <i>grand coup</i>)	4500
Four aces of trumps	1000
Four tens of trumps	900
Four kings of trumps	800
Four queens of trumps	600
Four knaves of trumps	400
Four aces	100
Four kings	80
Four queens	60
Four knaves	40
The last trick	250

The game is won by the player who scores the most points. The winner deducts the score of the loser from his own score, and adds 1,000 points for the game. If the loser fails to score 3,000 points he is rubiconed; i.e., the winner adds the two scores together with the addition of the 1,000 points for winning the game. If neither player scores 3,000 points, the one who scores the greater number of points wins a rubicon.

After both players have played to a trick they each draw another card from the stock. The winner of the trick draws first.

After a player has won a trick he may make any declaration that he has. Declared cards must be exposed, face upwards, on the table and must remain so until they are played.

If a declared card be played, and a card which restores any declared combination be substituted, the combination may be declared again and scored again at its full value:—thus, if a player has declared four aces he may play one of them and score 100 points again on putting down another ace. If he has declared a sequence he may part with any card of the sequence in play and score another 250 points on putting down a card similar to the one played.

After the stock is exhausted the players take their declared cards into their hands and play them out. Each player must follow suit when able and must head the trick if he can. If he has none of the suit led he must trump. The winner of the last trick scores 250 points.

See Charles Goodall & Co., *The Royal Game of Bézique* (1868); Scribner, *Complete Guide to the game of Bézique* (1874); The International Card Co., *Rubicon Bézique* (1005); F. Jessel, *The Laws of Six Pack Bézique* (1921). (W. DA)

BÉZOUT, ÉTIENNE (1730–1783), French mathematician, was born at Nemours on March 31, 1730. He studied mathematics in opposition to the wishes of his parents. In 1763 he became examiner of naval entrants in mathematics, and a few years later he undertook similar work for the artillery. Bézout wrote two text books, *Cours de mathématiques à l'usage des gardes du pavillon et de la marine, avec un traité de navigation* (1764–69) and *Cours de mathématiques à l'usage du corps royal de l'artillerie* (1770–72). These were adopted in a number of schools; they ran into many editions and were translated into other European languages. He was very conscientious in his work as an examiner, and in the limited time at his disposal for mathematical research he studied the theory of equations. Bézout's work on this subject was of great value to the geometers of the time, who were being hindered by the lack of knowledge in algebra. He published papers in the *Histoire de l'Académie Royale des Sciences* in 1764 and 1768. In the first of these papers he used determinants, but did not deal with their general theory. His most important work was the *Théorie générale des équations algébriques* (1779), which contained much valuable material on the theory of elimination. Bézout was a member of the Paris Academy; he died of fever on Sept. 27, 1783.

BEZWADA, a town of British India, in the Kistna district of Madras, on the left bank of the river Kistna, at the head of its delta. Pop. (1921) 44,159. Here are the headquarters of the Kistna canal system, which irrigates about 700,000 acres, and also provides navigation throughout the delta. There are rice-mills, and cotton-ginning and -pressing factories. The town is an important trade centre and the junction of 5 railways, and has increased largely in population in recent years. The anicut or dam at Bezwada, consists of a mass of rubble, fronted with masonry, 1,240 yards long. Ancient cuttings on the hills west of Bezwada have been held by some to mark the site of a Buddhist monastery; by others they are considered to have been quarries. At Undavalle to the south are some noted cave-shrines.

BHAGALPUR, town of British India, in the Behar Section of Behar and Orissa, which gives its name to a district and to a division; situated on the right bank of the Ganges, with a station on the East Indian railway. Pop. (1921) 68,878. The chief educational institution is the Tejnarayan Jubilee college. There are two monuments, one erected by government, and the other by the landholders, to the memory of Augustus Cleveland, who, as collector of Bhagalpur at the end of the 18th century,

"by conciliation, confidence and benevolence, attempted and accomplished the entire subjection of the lawless and savage inhabitants of the Jungleterry of Rajamahall." A silk institute has been established by government, which has introduced new kinds of silk to the weavers, who formerly only used tussur, and has produced artistic designs in coloured silk. Sabaur near the town is the headquarters of the agricultural department of the government of Behar and Orissa.

The District of Bhagalpur stretches across both banks of the Ganges. It has an area of 4,226sq.m. and a population (1921) of 2,033,770. It is a long and narrow district, divided into two unequal parts by the river Ganges. The north is a flat alluvial plain, mainly under rice cultivation and watered by a number of streams. Three fine rivers flow through the district—the Ganges, Kosi and Ghagri. The Ganges runs a course of 60m. through Bhagalpur. The Kosi falls into the Ganges near Colgong and receives the Ghagri 8m. above its debouchure. The tract south of the Ganges is traversed by the loop-line of the East Indian railway, and that to the north by the Bengal and North-Western railway. Rock sculptures of the 6th or 7th century exist at Patharghatta 8m. N.E. of Colgong; at the latter place a small rock-cut temple of A.D. 800 or 900 stands on a small hill close to the Ganges.

The Division of Bhagalpur stretches across the Ganges from the Nepal frontier to the hills of Chota Nagpur. It comprises the five districts of Monghyr, Bhagalpur, Purnea, Darjeeling, and the Santal Parganas. The total area is 18,613sq.m.; and in 1921 the population was 7,886,982.

BHAMO, a town and district of Burma. The town was in ancient times the capital of the Shan state of Manmaw, later the seat of a Burmese governor. It is now the headquarters of a district in the North-East Frontier division of Burma on the Chinese frontier. It is situated about 300m. up the river Irrawaddy from Mandalay and so nearly a thousand miles by river from the sea. It is normally the highest point reached by the regular services of launches of the Irrawaddy Flotilla Company. It is also the nearest point on the river to the Chinese frontier. In 1921 it contained 7,741 inhabitants, of whom a considerable number were Chinese, natives of India and Chinese-Shans. It stretches for a distance of nearly 4m. along the Irrawaddy bank in a series of small villages, transformed into quarters of the town, but the town proper is confined mainly to the one high ridge of land running at right angles to the river. The surface of the ground is much cut up by ravines which fill and dry up according to the rise and fall of the river. When the Irrawaddy is at its height the lower portion of the town is flooded, and the country all round is a sheet of water, but usually for no very long time. Here or thereabouts has long been the terminus of a great deal of the land commerce from China.

The district of Bhamo lies wholly in the basin of the Irrawaddy, which, as well as its tributaries, runs through the heart of it. On the east of the river is the Shan plateau, running almost due north and south. West of the Irrawaddy there is a regular series of ranges, enclosing the basins of the Kaukkwe, Mosit, Indaw and other streams down which much timber is floated. (L. D. S.)

BHANDARA, a town and district of British India in the Nagpur Division of the Central Provinces. The town (pop. 1921, 14,000) is situated on the left bank of the River Wainganga, 7 miles from a station on the Bengal-Nagpur Railway. It has considerable manufactures of cotton cloth and brass-ware, and, besides all the ordinary institutions at the headquarters of a district, it has a Government High School and subsidiary schools attached to it.

The District of Bhandara has an area of 3,623 square miles, having lost some 300 square miles by transfer to the Balaghat district. Its population declined by 11% in the famine decade, but has now recovered, and in 1921 was 717,747. It is a beautiful, well-wooded district containing over 3,000 small lakes and tanks, and in the last 20 years several Government Storage Works for irrigation have been constructed. The eastern portion, on the borders of the Chhattisgarh, is very hilly, and there are small wooded hills dotted over the whole country. The strip of country

on the north-west produces Juar (big millet). In the south-west there is a fertile plain near Powni, where wheat is the chief crop. Apart from these tracts, Bhandara is a rice-growing country, a considerable area being irrigated from its lakes and tanks.

The Great Eastern road and the Bengal-Nagpur railway traverse the district from west to east, on the way between Nagpur and Calcutta. At Gondia, a trading centre, two narrow gauge branch lines join the main line, one leading to Jubbulpore on the north, and the other to Chanda in the south.

The wilder areas of the district are to be found in the Zamin-daris, or the estates of ancient feudal proprietors, who hold them on a favoured tenure continued from Mahratta days. Ponwars are the best cultivators, and Kohlis are tank constructors and sugar cane growers of much repute. The beautiful Nawegaon Bandh lake was constructed by an ancestor of the present Kohli proprietor. There are colonies of weavers in some of the small towns, though this industry is declining. Otherwise the industries are all small. Cigarettes are extensively manufactured at Tirora from the tobacco of the country.

The chief towns in the interior of the district are—Gondia (10,607); Powni, an old walled town and fort (10,481); Tumsar (6,692).

There are extensive deposits of high-grade manganese in the north-west of the district, exporting some 300,000 tons of ore. A branch line from Tumsar to serve these mines is under construction.

The district has developed greatly, and its population has increased by 40% during the period 1878–1928. (R. H. C.)

BHANG, an East Indian name for the hemp plant, *Cannabis sativa* (see **HEMP**), but applied specially to the leaves dried and prepared for use as a narcotic drug. In India it is recognized under the three names and forms of Bhang, Gunja or Ganja, and Churrus or Charas. Bhang consists of the dark-green, aromatic, larger leaves and capsules of the plant on which resinous matter has exuded. Bhang is prepared in the form of a cake or man-jan, and is smoked, with or without tobacco, or is made into an intoxicating beverage by infusing in cold water and straining. Gunja is the flowering or fruit-bearing tops of the female plants. It is gathered in stalks of several inches in length, the tops of which form a matted mass, from the agglutination of flowers, seeds and leaflets by the abundant resinous exudation which coats them. Churrus is the crude resinous substance separated from the plant. The use of preparations of hemp among the Muslim and Hindu population of India is very general; and the habit also obtains among the population of central Asia, the Arabs and Egyptians, extending even to the negroes of the valley of the Zambezi and the Hottentots of South Africa.

BHARAHAT or **BARHUT**, a village in the small state of Nagod in India lying about 120m. S.W. of Allahabad. It is famed for the remains of an imposing *stūpa* which was excavated in 1874. The *stūpa* was circular, 70ft. in diameter and 42ft. high. It was surrounded by a stone railing 100ft. in diameter so that between railing and *stūpa* there was an open circle round which visitors could walk; and the whole stood towards the east side of a paved quadrangle about 300ft. by 320ft., surrounded by a stone wall. The railing consisted of 80 square pillars, 7ft. 1in. in height, connected by cross-bars about 1ft. broad. Both pillars and cross-bars were elaborately carved in bas-relief, and most of them bore inscriptions giving either the name of the donor, or the subject of the bas-relief, or both. The forms of letters of the inscriptions, and the architectural details fix the date of the monument in the 3rd century B.C. The bas-reliefs tell of the literature, clothing, buildings and other details of the social conditions of the peoples of Buddhist India at that period; and they emphasize how much more prominent the Tibetan type of Indian was in the north than it is to-day. Unfortunately only about half the pillars, and about one-third of the cross-bars have been recovered. When the *stūpa* was discovered the villagers had already carried off the greater part of the monument to build their cottages with the stones and bricks of it. The process has gone on till now nothing is left except what Gen. Cunningham found and rescued and carried off to Calcutta.

BHARAL (būr'al), the Tartar name for the "blue sheep" *Ovis nakura*, of Ladak and Tibet. The general colour is blue-grey with black "points" and white markings and belly; and the horns of the rams are olive-brown and nearly smooth, with a backward curvature. The bharal serves to connect sheep (q.v.) with goats.

BHARATPUR or **BHURTPORE**, an Indian State in the Rajputana agency. Its area covers 1,982 sq.m., and its population in 1921 was 496,437. The country is generally level, but detached hills, rising to 200ft. in height, occur, especially in the north. These hills contain good building stone and some of them iron ore. The Banganga is the only river which flows through the State, on its way to the Jamna below Agra.

Bharatpur rose into importance under Suraj Mall, a Jat chieftain, who founded the present ruling family and bore a conspicuous part in the destruction of the Delhi empire. Having built the forts of Dig and Kumbher in 1730, he received in 1756 the title of rajah, and subsequently joined the great Mahratta army with 30,000 troops. In 1803 the East India company concluded a treaty, offensive and defensive, with Bharatpur. In 1804, however, the rajah assisted the Mahrattas against the British. Lord Lake captured the fort of Dig and besieged Bharatpur, but was compelled to raise the siege after four attempts at storming. A treaty, concluded on April 17, 1805, guaranteed the rajah's territory; but a dispute as to the right of the succession again led to a war in 1825, and Lord Combermere captured Bharatpur with a besieging force of 20,000 men, after a desperate resistance, on Jan. 18, 1826. The fortifications were dismantled, the hostile chief being deported to Benares, and an infant son of the former rajah installed under a treaty favourable to the company. In 1853 the State came under British management during a minority, and the administration was improved, the revenue increased, a system of irrigation developed, tanks and wells were constructed and an excellent system of roads and public buildings was organized. The present maharajah succeeded in 1900, maintains a fine force of imperial service troops, and enjoys a salute of 17 guns.

The City of Bharatpur is 34m. W. of Agra by rail. The population in 1921 was 33,495. The immense mud ramparts still stand. It has a handsome palace, a new hospital and a high school. There are special manufactures of *chawris*, or flappers, with handles of sandalwood, ivory and silver, and tails also made of strips of ivory or sandalwood as fine as horsehair. The splendid palace of Suraj Mall is at Dig, 21m. from Bharatpur.

BHĀSCARA (b 1114), known as Acārya (the learned), Indian astronomer and mathematician, was the head of an observatory at Oudjein. He wrote in verse on astronomy and mathematics, the *Siddhantashiromani*. The chapters on mathematics were translated by Colebrooke with the work of Brahmagupta (q.v.) and those on astronomy by L. Wilkinson (Calcutta, 1842). It is practically certain that Bhāscara was acquainted with Arabic writings on mathematics, and it seems that the results of his own work were known in Europe in the 12th century. In Bhāscara's work the Arabic numerals are used, and he was the first writer to give a systematic exposition of the decimal system. He enunciates the ordinary rules of arithmetic, arithmetical and geometrical progressions, simultaneous and quadratic equations, and some trigonometrical formulae. The book incidentally throws much light on economic conditions of the time, on the price of slaves, the rate of interest and so on.

See the *Dissertation* by Colebrooke, prefixed to his edition (1817); W W Rouse Ball, *Short Account of the History of Mathematics*; Cantor, *Geschichte der Mathematik* (vol. i., 3rd ed., 1906).

BHATGAON, a town of Nepal, 8m from Kathmandu. It is a celebrated Hindu religious centre, the favourite residence of the Brahmans of Nepal, and contains more families of that order than either Kathmandu or Patan. It has a population of about 30,000 and its palace and buildings generally are of a more striking appearance than in other Nepalese towns. The town is said to possess many Sanskrit libraries.

BHATIA: see CASTE.

BHATTIANA, a tract in the Punjab, India, covering the Ghaggar valley from Fatehabad in Hissar to Bhatnair in Bikanir.

In 1795 it was nominally under George Thomas, the Haryana adventurer, and after Lord Lake's victories (1803) it passed with the Delhi territory under British rule, but was not settled until 1810. A district of Bhattiana was formed in 1837; in 1858 it was merged in the Sirsa district, which was divided up in 1884.

The district derived its name from the Bhattis, a Rajput clan, who held the country between Haryana, Bikanir and Bahawalpur.

The Bhattis are a fine tall race, making capital soldiers, agriculturalists and horse-breeders.

See H. A. Rose, *Glossary of the Tribes and Castes of the Punjab and North-West Frontier Provinces*, 3 vols. (1911-14).

FROM RUSSELL, "TRIBES AND CASTES OF CENTRAL PROVINCES OF INDIA"

A NATIVE OF BHATTIANA WITH HIS PUTLA, OR DOLL

BHAU DAJI (RAMKRISHNA VITHAL) (1822-74), Hindu physician, scholar and antiquary, was educated at the Elphinstone college in Bombay, where he eventually joined the teaching staff. Both he and his brother, NARAYEN DAJI, were physicians of note. Bhau Daji took an active interest in Bombay university, of which he was one of the original fellows, and was a champion of female education. In spite of his busy life as a physician in Bombay, he found time to study Indian antiquities, the medical methods of the ancient Hindus, and the history of leprosy. He left a valuable collection of Sanskrit mss. Dr. Daji's unbounded charity to the poor of Bombay caused his memory to be cherished in the city where his life was spent.

BHAVNAGAR or **BHAUNAGAR**, a native State of India in the Kathiawar agency, Bombay: area, 2,860sq.m.; pop. (1921), 426,404. The tribute is £8,500. The chief, whose title is *thakor sahib*, is head of the famous clan of the Gohel Rajputs of Kathiawar. The enlightened system of administration formed during the rule of the thakor sahib maharaja Sir Takhtsinghji Jaswatsinghji, G.C.S.I., was continued with admirable results under the personal supervision of his son. His grandson, Krishna Kumak Singhji, succeeded as a minor in 1919, since when the State has been governed by an administrative council. The Gohel Rajputs are said to have settled in the district about 1260. The Bhavnagar-Gondal railway (282m.) has its terminus at the town of Bhavnagar (pop., 1921, 59,392), situated on the west coast of the gulf of Cambay. This is the chief port in Kathiawar and is well equipped, though only admitting vessels of small burden. It was founded in 1723 by the thakor sahib Bhausinghji, after whom it is named, in place of his former capital, Sihor, which was considered too exposed to the Mahratta power; it has an extensive cotton trade and its industries include a cotton mill and iron and tile works.

BHEESTY, the Hindustani name for a water carrier (Persian *bihisti*, paradise).

BHERA, a town in British India, Shahpur district, Punjab, on the river Jhelum. Pop. (1921) 17,027. It is an important centre of trade, with manufactures of cotton goods, metal-work and carving.

BHİL, an aboriginal, probably Munda, tribe of central India (fr. Dravidian *bil*, "bow"). Its language only survives in about 6% of its vocabulary and it now speaks a mixture of Guzerāti and Mālwi. Possibly the pygmies of Ktesias and the Phyllitae and Pulindae of Ptolemy, its name is hardly traceable in Sanskrit literature but may appear as Pulinda in Asoka's edicts and later. The present home of the Bhils is the wild, hilly country between Mt. Abu and Asirgarh, whence they have spread west into Guzerāt, and of late even into Sindh, and south into the Deccan. The typical Bhil is small, dark, broadnosed, but well-knit and active, a good woodman and hunter but a poor ploughman. He still wears his hair long, and his womenfolk plait theirs into three tails. The men still carry a bow or axe. Divided into 40 totem-clans,

they owe military service to village headmen and chiefs of cantons. In religion the Bhil is not yet fully Hinduized, since in famines he will eat beef, but not snakes, rats, monkeys or the horse. His chief god is Vāghdeo, the "tiger," and he propitiates ghosts, but he makes oath on the moon, or a dog, and reveres Devi and Hanumān of the Hindu pantheon, while the chief Hindu festivals are riotously celebrated. Superstition is rife.

The Bhils claim to have once been much more numerous and to have held principalities in Rājputāna and its adjacent lands. A respectable tradition in *The Ocean of Story* avers that a ruler of Ujjain once espoused a Bhil princess whose father promised him an aid of 20,000 archers. In Rājputana the tribe must have given its name to Bhilwāra, the "Bhil county," a district and town 80m. north-east of Udaipur; they are now in the hilly tracts of Kherwāra and Kotra, the people of which are almost wholly Bhil. Near the latter lies Dungarpur, the Bhil ruler of which, Dungaria, was killed about A.D. 1200 by a scion of Udaipur who expelled the Bhils, named his new capital after his victim and promised his widows that on accession its chieftain's forehead should be marked with blood from the toe or finger of a descendant of Dungaria—a usage also observed till recently in Banswāra and Udaipur itself. Similarly Kotah was wrested from its Bhil Rājā by a cadet of Bundi. In the Central India Agency another Bhilwāra, a sparsely peopled tract, lies in the Narbada valley betwixt the Vindhya and the Satpura Range. The local aristocracy in the Vindhya is formed of Bhilālas, a mixed tribe of Rājput and Bhil origin, headed by the Rājā of Onkar Mandhātā in the Central Provinces, where Rājputs did not in earlier days disdain to eat with Bhils whom they regarded as lords of the soil. Hence the Bhil claim is undoubtedly well founded, but his early history is lost and how far his ancient domains extended cannot be ascertained. His hostility to the Rājputs made him submissive to the Moghuls, but the Marathas renewed his persecution, and British rule found him at a low ebb. In 1825 a policy of reclamation replaced one of force. The Bhil Agency was formed in Khandesh, and in 1840-44 the Mewār Bhil Corps was raised with headquarters at Kherwāra. One of the few Indian regiments which remained loyal in the Mutiny, service in it has been popular and has done much to elevate the tribe. Given its colours in 1863, it was placed under the Commander-in-Chief in 1897.

BHĪMA, in the epic Hindu mythology, one of the Pāndava princes in the *Mahābhārata*, distinguished by his size, strength and voracity (Skt. "Terrible").

BHIWANI, town, British India, Hissar district, Punjab, 38m. S.E. of Hissar town by rail. Pop. (1921) 33,270. It is an important centre of trade with Rajputana, and has factories for ginning and pressing cotton, and metal manufactures.

BHOIS: see CASTE.

BHOPAL, BEGUM OF, Nawab Sultan Jahan (1858-), was the fourth woman in succession to rule Bhopal, a State of about 7,000 sq.m. in central India. Sprung from an ancient stock of Afghan invaders, she was married in 1874, and succeeded in 1901. She was keenly interested in the education and medical care of women, and encouraged agricultural and industrial development. She visited Europe in 1911 and 1925, and secured the nomination of her son as her successor. She maintained a regiment of Imperial Service Cavalry, and was entitled to a salute of 21 guns within and 19 outside her own territory. On May 18 1926 the viceroy approved her decision to abdicate in favour of her son.

BHOPAL, an Indian State in the Central India Agency. Its area is 6,902 sq.m., and its population in 1921 was 692,448. Bhopal is the principal Muslim State in Central India, and second only to Hyderabad for the whole of India. The surface of the country is uneven, being traversed by the Vindhya ranges, a peak of which near Rayzen is upwards of 2,500ft. above sea-level. The general inclination of the country is towards the north, in which direction most of the streams of the State flow, while others, passing through the Vindhya ranges, flow to the Nerbudda.

Bhopal State was founded in 1723 by Dost Mohammed Khan, an Afghan adventurer. In 1778, when Gen. Thomas Goddard made his bold march across India, the State of Bhopal was the

only Indian Power that showed itself friendly; and in 1817, at the outbreak of the Pindari War, a treaty was concluded between the chief and the British Government. Since then Bhopal has been steadily loyal to the British Government, and during the Mutiny it rendered good services. The throne descended in the female line from 1844, when Sikandar Begum became ruler, until 1926, when Sultan Jahan Begum abdicated in favour of her third and only surviving son. Succeeding begums have taken a great

interest in the work of governing the State, which they carried on with marked success. Sultan Jahan Begum, who succeeded on the death of her mother, Shah Jahan Begum, in June 1901, was the only female ruler in India, and attained a unique position by her strength of character, sagacity and enlightenment. She reorganized the whole Administration, advanced education and medical aid, and devoted herself especially to the amelioration of the condition of women in her State.

The State pays the British Government a subsidy for the Bhopal battalion, and maintains also a force of imperial service troops. The residence of the political agent and the headquarters of the Bhopal battalion are at Sehore, 20m. W. of Bhopal city. The city of Bhopal had a population in 1921 of 45,094. The palace, with its rock fortress, is called Fatehgarh. An excellent water-supply has been provided from two large artificial lakes.

BY COURTESY OF THE INDIAN STATE RVS.
ANCIENT COLUMN AT SANCHI, BHOPAL.

Called the Assyrian Tree of Life, this column belongs to one of the tops, or burial mounds, that are believed to be the oldest extant buildings in India. They are thought to date from the 3rd century B.C.

Bhopal agency, an administrative section of Central India, takes its name from the State of Bhopal, which is included in it. The Bhopal agency is administered by the agent to the governor-general in Central India.

BHOPAWAR, an agency in Central India. It consists of the Dhar and Barwani States, three minor States, Ali Rajpur, Jhabua and Jobat, and a number of districts and estates, some of them minute in area. The chief towns are Dhar (pop., 16,041), Barwani (8,395), and Kukshi (6,377).

BHOR, a native State of India, in the Poona political agency, Bombay, situated among the higher peaks of the Western Ghats. Its area covers 925 square miles. Pop., 1921, 130,420; the tribute is £312. The chief, whose title is *pant sachiv*, is a Brahman by caste. The town of Bhore is 25m. S. of Poona. Pop., 1921, 4,088. The Bhore Ghat, on the northern border of the State, has always been the main pass over the Western Ghats between the sea-coast and the Deccan, and is traversed by the main line of the Great Indian Peninsula railway.

BHUJ, a town of India, the capital of the native state of Cutch, in the Gujarat division of Bombay, situated at the base of a fortified hill, on the north side of the Ran of Cutch. Pop. (1921) 19,281. It is well known for its silver work. It contains some interesting examples of architecture of the middle of the 16th century and later.

BHUTAN, an independent state in the eastern Himalayas, lying between Tibet and British India, with the latter of which the boundary marches for about 200 miles. It is bounded on the east by a tract inhabited by savage tribes, such as Abors and Mishmis, called by the Tibetans Kha Lo and Ting Lo, i.e., savages at the entrance and savages at the bottom; and on the west by the State of Sikkim and the district of Darjeeling. The whole of Bhutan presents a succession of lofty and rugged mountains running generally from north to south and separated by deep

valleys. The principal ranges, proceeding from west to east, are the Masong-chung-dong between the rivers Amo-chu and Wang-chu; the Dokyong-la between the Wang-chu and Ma-chu; the Black Mountain range between the Ma-chu and the Manas, which is traversed by the Pele-la pass; and on the extreme east the Tawang range.

The country, so far as it is known, is divided into three distinct tracts. Proceeding from south to north the first tract about 30m. broad consists of the outer hill ranges, which, rising from the plains of India, intercept the moisture-laden winds coming from the Bay of Bengal; they are consequently subject to a heavy rainfall, of 200 to 300in. annually, and are clothed in dense vegetation. The second or central tract, which is about 40m. in width, comprises a number of valleys, lying at an elevation of 3,500 to 10,000ft. above sea level and separated by high mountain ridges. The slopes of the mountains are gentler; the rainfall averages only 40 to 60in.; the valleys such as those of Paro, Ha and Punaka, are broad and under cultivation; and it is here that the bulk of the population is found. The east of Bhutan, however, where the outer range is lower than it is to the west, is a region of heavy precipitation, as the monsoon travels up the valley of the Kuru-chu as far as the snowy range. The third or northern tract consists of more rugged mountains and of snowy ranges rising to 24,000ft., with Alpine valleys lying at a height of 12,000 to 18,000ft., which are frequented only by graziers and their herds of cattle. Bhutan is drained by numerous rivers, which, forcing their passage through narrow defiles, eventually pour themselves into the Brahmaputra. The largest is the Manas, which has two main tributaries, the Kuru-chu or Lhobrak and the Dangme-chu; the Amo-chu, known as the Torsa in India, which flows down the Chumbi valley between Bhutan and Sikkim; the Wang-chu or Raidak draining the Ha, Paro and Trashi-chöd-zong valleys; and the Ma-chu, which flows through the Punaka valley and in its course through the plains is called the Sankosh. As is natural in a country rising from low valleys to perpetual snow, every kind of climate is to be met with. The lower valleys are saturated with moisture, hot and steamy; the central valleys, according to their elevation, may be bathed in hot sunshine or enjoy a temperate coolness; the extreme north has the rigours of frost and ice. Similarly there is every variety of vegetation. The lowest slopes are covered with dense semi-tropical vegetation and virgin forest. In the temperate tract the mountain heights and ridges are covered with coniferous forests (fir, pine, spruce and larch) and with rhododendrons; oaks, beech, ash, maple, cypress and yew are also common on the slopes below them. Higher up there are grassy slopes, but gradually all vegetation disappears.

Fauna.—The lower ranges abound in animal life. of the hills to the east of Bhutan J. C. White wrote "They are the haunt of almost every kind of wild animal—elephant, rhino, tiger, leopard, bison, mythun, sambur, cheetah, hog-deer, barking deer, etc." Bears are also found and musk deer in the snows. Pheasants, jungle fowl and other small game abound. The country has also been long famous for its sturdy and strong though small horses or ponies, about 13 hands high, which are admirably suited for rough mountain work. They are called *tangan*, probably from a Tibetan name for this kind of horse, and are mentioned in the *Ain-i-Akbari* of the 16th century. In the treaty of 1774 between the East India Company and Bhutan it was stipulated that the Deb raja should pay an annual tribute of five "Tangan horses."

LAMA PRIEST BEFORE A SHRINE IN BHUTAN
Equipped with a prayer wheel and beads, he is ready to perform his duties of worship. The decorations on the trees and poles, in the background, are religious symbols

Area and Population.—Nothing is known with certainty of either the area of Bhutan or of the number of its inhabitants. The former has been estimated at 16,800 square miles. The population is believed to number only a few hundred thousand and is chiefly concentrated in the central valleys. There are clear indications, such as the ruins of houses and the remains of old irrigation channels, that the country was formerly more thickly populated than it is at present; and it has been estimated that, with its fertile soil, it is capable of supporting 1½ million persons by agriculture. The dominant race consists of the Bhotias, who are of Tibetan origin: the name Bhutan itself is a contraction of the Indian name Bhotanta meaning the end of Bhot (*i.e.*, Tibet). They speak a dialect of Tibetan: their religion is the same form of Buddhism as is prevalent in Tibet. They differ from the Bhotias of Tibet and Sikkim in one respect: both men and women have close cropped hair and do not wear pig-tails. Along the foothills to the west of the Amo-chu river the Bhotias have been supplanted by the Nepalese, thrifty cultivators, who eagerly take up waste lands and convert them to tilth. They are not allowed to cultivate east of that river, where they would bring the Bhotias' grazing land under the plough. The people living to the east of the Black Mountain range appear to have affinities with the Assamese and eastern frontier tribes. Their stature is smaller, their complexion is darker, and their features are smaller than those of the Bhutanese west of the range, who are big, burly men with typical Mongolian features. The chief places and centres of population are Punaka, the old winter capital, Trashi-chöd-zong, the summer capital, Tongsa, Paro and Ha. The lamas or priests are the religious, and the Penlops or chiefs the temporal authorities under the maharaja. The lamas are regarded with superstitious dread and reverence by the people who ascribe to them supernatural powers. There are nine provinces under eight Penlops, who resemble feudal barons and have retainers armed with helmets, hide shields and swords. Their forts (*dzongs* or *jongs*) are like baronial castles dominating the valleys. These *jongs* are of vast size, some having accommodation for 2,000 and more persons. Of the Paro *jong* Lord Ronaldshay wrote: "One is overwhelmed by its immensity, and one's critical faculties are swamped by the one dominant impression which it leaves upon one's mind—that of size." They have a distinctive style of architecture—walls sloping slightly inwards (as in Tibet), shingle roofs, large courtyards and a square central tower or keep. The monasteries, also often of great size, are generally most picturesquely situated: that of Ta-tsang is built on the face of a perpendicular crag, over 2,000ft. in height, and appears literally to cling to the rock. A distinctive feature of the chief altars in the monastery chapels is that they are supported by a pair of elephant's tusks. The ordinary houses, with their wooden walls and roofs and projecting eaves, resemble Swiss chalets: no iron work is used, and even the doors turn on wooden hinges. The chief crops are maize, which grows up to a height of 7,000ft. above sea-level; rice, for which Bhutan is the chief source of supply for Tibet; *marua*, a millet which, when fermented, yields a stimulating and mildly intoxicating drink; barley, which when distilled produces a potent spirit called *chang*; wheat, buckwheat and mustard. The fields are laid out in a series of terraces cut out of the sides of the hills and supported by stone embankments. An ingenious system of irrigation is practised, the water being often brought a long distance by aqueducts. The chief industries are metal work, the weaving of strong and durable cloth, fine basket and mat work. The Bhutanese are expert joiners and also excel in metal work, silver, iron, copper and brass. A high degree of skill is shown in the temple vessels, swords and daggers which they produce: the designs are Chinese in character. The making of needlework pictures on temple banners is a special art of the lamas, and bell-casting of the artificers. Iron ore is obtained from mines at Bor-shang. The roads, as a rule, are rough mountain tracts. In the valleys the rivers are in some places spanned by bridges constructed on the cantilever principle, and in ravines by suspension bridges with chains of wrought iron and a narrow roadway of planks or bamboos. Rice is exported to Tibet, but trade is tending more and more in the direction of India, where it has been

stimulated by fairs in the Darjeeling and Jalpaiguri districts of Bengal and in the Darrang district of Assam. The bulk of the trade is insignificant and much of it is conducted by barter.

The Dharm Raja and the Deb Raja.—At the head of the Bhutan Government there were formerly two supreme authorities, the Shab-tung Rim-po-che, known in India as the Dharm raja the spiritual head, and the Deb raja who was the temporal ruler, with a council of permanent ministers. The Dharm raja is regarded as an incarnation of Buddha. On the death of a Dharm raja a year or two elapses, and the new incarnation is then reborn in one of the ruling families. When able to speak, the child establishes his identity by recognizing the rosary, books, etc., of the Dharm raja. He is then trained in a monastery, and on attaining his majority assumes supreme pontifical power. The Deb raja was in theory elected by the council. In practice he was merely the nominee of whichever of the governors (Penlops) of Paro and Tongs (east and west Bhutan) happened for the time to be the more powerful. This system has fallen into desuetude. The Tongsa Penlop (Sir Ugyen Wang-chuk, K.C.I.E.), having overcome his rivals in a civil war, became predominant after 1885. The Dharm raja died and no reincarnation was found. Pending a reincarnation the supreme spiritual authority was vested in the Deb raja, who withdrew from mundane affairs and became a religious recluse. The administration of Bhutan passed into the hands of the Tongsa Penlop, who in 1907 was elected hereditary maharaja of Bhutan by the abbots, lamas, councillors and people.

History.—Of the early history of Bhutan little is known but according to the best Bhutanese record Tibetan troops invaded the country at the end of the 9th century A.D., and "drove out the Indian princes and their subjects" and then settled down in occupation of the land. When the British assumed dominion in Bengal, Bhutan was more extensive, for it included part of Darjeeling on the east and the Duars of Jalpaiguri on the south, i.e., a strip of submontane country and the passes from the plains. The relations of the British with Bhutan commenced in 1772, when the Bhutanese invaded the principality of Cooch Behar and took the raja away as a captive. In response to an appeal for assistance, Warren Hastings sent a force which drove out the invaders and pursued them into their own territories. Upon the intercession of the Tashi Lama, then regent of Tibet, a treaty of peace was negotiated in 1774. Warren Hastings sent Bogle in 1774 and Turner in 1783 as emissaries to Bhutan, with a view of promoting commercial reciprocity; but little intercourse took place until the occupation of Assam by the British in 1826. It was then discovered that the Bhutanese had usurped the Duars in the Darrang district of Assam, and for these they agreed to pay a small tribute. They failed to pay, however, and committed depredations within the British territory. Capt. R. B. Pemberton was accordingly deputed to Bhutan, but his negotiations yielded no definite result. Every other means of obtaining redress and security proving unsuccessful, the Assam Duars were annexed in 1841, and the British Government consented to pay to Bhutan a sum of Rs.1,000 per annum so long as the peace was kept.

Scarcely a year passed, however, without the occurrence of raids in which the Bhutanese plundered, massacred or carried away British subjects as slaves. At last in 1863 Sir Ashley Eden was sent as an envoy to Bhutan to demand reparation for these outrages. He was kept in duress and subjected to the grossest insults; and under compulsion signed a treaty giving over the disputed territory to Bhutan. After Sir A. Eden had made his escape, the viceroy disavowed his treaty, stopped the allowance for the Assam Duars and demanded the immediate restoration of British captives. The Bhutanese not complying with this demand, Bhutan was invaded in 1865. The Bhutanese surprised an English garrison at Dewangiri, and the post was abandoned with the loss of two mountain guns. This disaster was soon retrieved and the Bhutanese were compelled to sue for peace, which was concluded in Nov. 1865. Bhutan ceded all the Duars of Bengal and Assam, with the rest of the territory taken from them, and agreed to liberate all kidnapped British subjects. The British Government, in return for these concessions, undertook to pay an annual allowance subject to the condition of continued good behaviour.

Since that time the relations between the Indian Government and Bhutan have been satisfactory.

During the present century Bhutan has been brought into closer relations with India. The treaty of 1865 has provided that disputes between Bhutan and Sikkim or Cooch Behar should be referred to the British Government. These provisions were amplified by a treaty concluded in 1910, by which the Bhutanese Government agreed to be guided by the advice of the British Government in regard to its external affairs, while the British Government undertook to exercise no interference in the internal administration of Bhutan. The annual allowance was at the same time raised to Rs.100,000 a year. This treaty disposed of claims made by China and provided a safeguard against Chinese aggression. In the same year the Chinese Government formally claimed Bhutan as a feudatory and was informed by the British minister at Peking that Bhutan was independent of China and its external relations were under the British Government, which would not tolerate any attempt by China to exercise influence over Bhutan.

See J. Claude White, *Sikkim and Bhutan* (1909); Earl of Ronaldshay, *Lands of the Thunderbolt* (1923); Sir Charles Bell, *Tibet, Past and Present* (1924).

BIAFAR, a Portuguese Guinea people related to the Bagnun, Balante, Mandjak, Bola and Papel, and located on the right bank of the Geba estuary.

See Dr. Maclaud, "Distribution des races sur la côte occidentale d'Afrique," *Bulletin Géogr. hist. descript.* (1906).

BIALIK or **BYALIK**, **CHAIM NACHMAN** (1872–), the greatest Hebrew poet of modern times, was born in 1872, at Radi, in the province of Volhynia, Southern Russia. His father was an innkeeper, but a scholar. When the boy was 6, the family removed to Zhitomir, and a year later the father died, leaving the widow and family in great poverty. Young Bialik subsequently lived with his grandfather, and although fond of frolic and indisposed to study, was a quick pupil at the Cheder (Hebrew school). The love of nature, which he gained in the woods in his early days, and the poverty and gloom of the Cheder life, are reflected in his poems. He wished to go to the University of Berlin, but this was impossible, and he became a student at the noted Yeshibah (Rabbinical seminary) of Volozhin. When he grew up he left for Odessa where he came under the notice of "Achad Ha-am," the nom-de-plume ("One of the People") of Asher Ginzberg, the Hebrew philosopher and literateur, to whose publication, "Hashiloach," he contributed Hebrew poems which quickly attracted attention. His "In the City of Slaughter," a poem prompted by the Kishineff pogrom of Easter 1903, not only gained him renown but stirred the emotion of the Jews, inspired them to self-defence, and gave impulse to the Zionist and nationalist movement. Bialik was now recognized as a force in the revival of Hebrew; with his friend Ravnitzki, he started a successful printing and publishing business in Odessa and produced Hebrew literature, new and old, which considerably influenced the Hebrew renaissance. During the World War Bialik virtually ceased to write, for poets, he said, were not needed and the Jews should learn to face the stern realities of life; he has been almost silent ever since. Escaping impoverished from Russia to Berlin in 1921 he revived the publishing firm, "Dvir," with which Dr Shmarya Levin, the Zionist orator, has also been since associated. A few years later it was transferred to Tel-Aviv, the Jewish suburb of Jaffa, where it produces original works in Hebrew, revisions of mediaeval rabbinical literature, and educational books. In 1926 Bialik visited England and America.

An English edition of some of his poems was edited by L. V. Snowman and published with an introduction by Vladimir Jabotinsky in 1924.

BIALYSTOK, a province of Poland, bounded north by Prussia and Lithuania; east by the province of Novogrodek, south by the provinces of Lublin and Polesie, and west by the province of Warsaw. Area, 12,597 square miles. It is a uniform plain, drained by the Niemen, Bobr, Narew and Bug, all navigable rivers. Granites and gneisses crop out along the Bug, Cretaceous, and especially Tertiary deposits elsewhere. The soil is mostly sandy. Forests, principally of conifers are of great extent, e.g.,

those of Augustov and Grodno, and part of the vast forest of Bialowieza (376 sq.m.), embracing wide areas of marshy ground. In the last-mentioned forest the wild ox survives, having been jealously preserved since 1803. Large peat bogs may be as much as 4 to 7 ft. thick. The climate is wet and cold. Agriculture is the predominant industry. The crops principally grown are potatoes, rye, oats, wheat, flax, hemp and some tobacco. There is a manufacturing industry, especially in woollens, distilling and tobacco. The woollen industry, centred at Bialystok, ranks second (after Lodz) in the republic. Other factories produce silk fabrics. The industrial area suffered great damage during the German occupation 1915-18, and after reviving in 1921, declined during the financial crisis of 1924. The province is crossed by main lines of railway from Warsaw to Leningrad and from Brest to the Prussian frontier. The population numbered 1,303,000 in 1921. Poles predominate (nearly 77%), then follow Jews (12.5%), White Russians (8.3%) and Lithuanians. The province is divided into 14 districts, the chief towns being Bialystok (*q.v.*), Grodno (34,900 in 1921), Lom'za, Bielsk, Suwalki, Augustov and Wolkowysk. The province was divided at the partitions of Poland between Germany and Russia, and was reunited to Poland in 1919.

BIALYSTOK, a town of Poland, capital of the province of the same name in 53° 8' N. and 23° 10' E., on the main railway line from Warsaw to Leningrad. Founded in 1320, it became part of Prussia after the third partition of Poland, but was annexed to Russia in 1807. Its development dates from 1845, when woollen mills were built; its population was 13,787 in 1857; 56,629 in 1889; and 77,000 in 1921, three-fourths being Jews.

BIANCHINI, FRANCESCO (1662-1729), Italian astronomer and antiquary, was born of a noble family at Verona. A paper by him on G. D. Cassini's new method of parallaxes was inserted in the *Acta Eruditorum* of Leipzig in 1685. He published separately: *Istoria Universale* (1697), only one volume of which appeared; *De Calendario et Cyclo Caesaris* (1703); *Hesperii et Phosphori nova Phaenomena* (1729), in which he asserted Venus to rotate in 24½ days; and (posthumously) *Astronomicae et Geographicae Observationes Selectae* (1737) and *Opuscula Varia* (1754).

See Fontenelle, "Eloge," *Mémoires de l'Acad. de l'Histoire*, p. 102 (1729); Mazzoleni, *Vita di Francesco Bianchini* (Verona, 1735).

BIARRITZ, watering-place, south-west France, in the department of Basses-Pyrénées, on the Bay of Biscay about 5m. W.S.W. of Bayonne. Pop. (1926) 18,382. A small fishing village in the early 19th century, it rose rapidly into importance under the patronage of the empress Eugénie, and is to-day the most frequented seaside resort of France. The climate is admirable at all seasons, and the situation of the town, at the foot of the Pyrenees where the pine-grown Landes (*q.v.*) merge into the rocky Basque coast, is unsurpassed. A magnificent promenade runs from the sandy Grand Plage, facing north-west, to the Côte des Basques, south of the triple Promontoire du Halde. The adjoining Promontoire de l'Atalaye has a mediaeval fort. These small peninsulas are surrounded by rocky islets, some of them united by jetties which enclose the Port de Refuge, available only in fair weather. The Côte des Basques is never without its foaming breakers, whence the name "Côte d'Argent" applied to the whole of the French Basque coast.

BIAS, of Priene in Ionia, one of the so-called Seven Sages of Greece, son of Teutamius, flourished about 570 B.C. The aphorisms attributed to him may be found collected in F. W. A. Mullach, *Fragmenta Philosophorum Graecorum* (1860). He is said to have written a poem on the best means of making Ionia prosperous. His advice to its inhabitants, at the time of the Persian invasion, to migrate to Sardinia and there found a single pan-Ionic city (Herodotus i. 170), has generally been regarded as historical. He was honoured with a splendid funeral, and a sanctuary called Teutamium was dedicated to him.

See Bohren, *De Septem Sapientibus* (1860), and Crusius' exhaustive article in Pauly-Wissowa, with bibliography.

BIAS, something oblique or slanting (Fr. *biais*, of unknown origin). The term is used especially of a piece of cloth cut obliquely across the texture, or of a seam of two such pieces

brought together. In the game of bowls (*q.v.*) it is applied alike to the one-sided construction of the bowl, and to the slanting line the bowl takes when thrown. The figurative sense of the word, prejudice or undue leaning to one side, is derived from this bowling term.

BIAxIAL CRYSTAL, a crystal having two optic axes, *i.e.*, two directions within the crystal in which the ordinary and extraordinary rays of light are propagated with the same velocity; *e.g.*, aragonite is a biaxial crystal and, in common with others, exhibits conical refraction (*q.v.*). (See **LIGHT**.)

BIBACULUS, MARCUS FURIUS, Roman poet, flourished during the last century of the republic. According to Jerome, he was born at Cremona in 103 B.C. He wrote satirical poems after the manner of Catullus, whose bitterness he rivalled, according to Quintilian (*Instit.* x. l. 196), in his iambics. He even attacked Augustus (and perhaps Caesar), (Tac. Ann. IV. 34). He was also author of prose *Lucubrations*, and perhaps of an epic poem on Caesar's Gallic Wars (*Pragmatia Belli Gallici*). Otto Ribbeck attributes to him one of the shorter poems usually assigned to Virgil. It is doubtful whether he is the person ridiculed by Horace (*Satires*, ii. 5, 40) and whether he is identical with the *turgidus Alpinus* (*Satires*, i. 10, 36), the author of an *Aethiopis* and of a poem on the Rhine.

See Weichert, "De M. Furio Bibaculo," in his *Poetarum Latinorum Reliquiae* (1830); fragments in L. Muller's edition of *Catullus* in the Teubner Series (1870).

BIBAUD, MICHEL (1782-1857), Canadian historian, was born at Côte des Neiges, Montreal, and educated at the Collège de Montreal. His *Histoire de Canada* (3 vols., 1837); dealing with Canadian history from its origins up to 1877, was pro-English and bureaucratic in tendency, thereby earning the condemnation of the French-Canadian public for whom it was written. Bibaud was the first French historian of Canada; he also wrote some satiric verse.

BIBER, HEINRICH JOHANN FRANZ VON (1644-1704), German violinist and composer, was for some time musical conductor at Salzburg, and was ennobled by the Emperor Leopold in 1681. He is regarded as the earliest important German composer for the violin.

BIBERACH, a town in the republic of Württemberg, Germany, on the Riss, a small affluent of the Danube, 22m. S.S.W. of Ulm. Pop. (1925), 10,065. It is still surrounded by mediaeval walls and towers, and has a 12th century church. Biberach became a free imperial city in 1312, but in 1803 it was deprived of its privileges and assigned to Baden, and in 1806 was transferred to Württemberg. The poet Wieland, born in 1733 at the neighbouring village of Oberholzheim, spent several years in the town. Its main industry is cloth, and its fruit markets are famous.

BIBIENA (BIBBIENA), GALLI DA, a family of Italian artists of the 17th and 18th centuries, who took their name from the birthplace of their progenitor, Giovanni Maria Galli (1625-65) born at Bibiena near Bologna. He was a painter, a pupil of Francesco Albani. He first laid the foundations of an artistry which was carried on by his descendants, who devoted themselves to scenic work for the theatre. Employing freely the highly ornate style of the Italian Late Baroque architecture and sculpture, the various members of the family produced a series of designs which are amazing for their splendour and spacious proportions. Bold perspective is called into the service of scenic staging. The work of the family was carried beyond the confines of Italy by members who were attached to the imperial court of Vienna and to other courts as architects and designers of theatrical festivities and court functions.

FERDINANDO GALLI BIBIENA (1657-1743), born at Bologna, was the son of Giovanni Maria. He studied painting under Carlo Cignani and architecture under Giulio Troili, called Paradossio. On Cignani's recommendation he entered the service of the duke of Parma. His chief work at this period was the villa and garden of Colorno. But he soon established a reputation for scenic designs and worked for the theatre. In 1708 he was called to Barcelona to arrange the decorations in connection with the wedding festivities of the future emperor, Charles VI., and when this prince ascended

the imperial throne he went to Vienna, and was there employed on designs of scenery and decorations for festivities at the court and at the opera. On his return to Bologna in 1717 he was elected a member of the Accademia Clementina. In 1731 he built the royal theatre of Mantua, burned in 1781. The church of S. Antonio Abate at Parma is attributed to him. He wrote the following works: *L'Architettura Civile preparata sulla geometria e ridotta alla Prospettiva* (1711); *Direzioni a giovani studenti nel Disegno del Architettura Civile* (1731 and 1745); *Direzioni della prospettiva teorica, corrispondenti a quelle dell Architettura* (1753).

FRANCESCO GALLI BIBIENA (1659-1739), born at Bologna, was the second son of Giovanni Maria. He studied under Parsinelli and Cignani, worked at Piacenza, Parma, Rome, and then became ducal architect at Mantua. After a stay in Genoa and Naples he was called to Vienna, where he built a large theatre. He was architect of the great theatre at Nancy, of the Teatro Filarmonico at Verona, which Milizia calls the finest theatre in Italy, of the Teatro Aliberti in Rome. In 1726 he returned to Bologna and was made one of the directors of the Accademia Clementina.

ALESSANDRO GALLI BIBIENA (1687-1769), eldest son of Ferdinando, was born at Parma. In 1719 he became architect and painter at the court of the elector of the Palatinate. Among his works we may mention the right wing of the Schloss and the Jesuit church at Mannheim.

GIUSEPPE GALLI BIBIENA (1696-1756), second son of Ferdinando, was the most distinguished artist of the family. He was born at Parma on Jan. 5, 1696. As a youth he accompanied his father to Barcelona and afterwards to Vienna. Staying on, when his father left, he there became the chief organizer of splendid court festivities and functions. He designed catafalques for the deceased members of the imperial family, and scenery for their plays and dances. In 1722 he worked in Munich; in 1723 in Prague. In 1742 he designed the decorations for the Vienna opera; in 1747 he was employed at the Opera in Dresden; in 1748 he designed the interior of the theatre at Bayreuth; and in 1750 renovated the Dresden opera. The following year took him to Berlin, where he died in 1756. In 1740 he published a collection of engravings of architectural designs, *Architettura e Prospettive dedicate alla Maesta di Carlo VI.*

ANTONIO GALLI BIBIENA (1700-1744), third son of Ferdinando, was the architect of the Accademia Virgiliana at Mantua and of the Teatro Comunale at Bologna. He was also employed at the court of Vienna.

As the Bibienas' works in theatrical scenery were not executed in durable material, and as their decorations for court functions were necessarily of a temporary character, little has survived, and we are only able to judge of their richness and splendour from drawings, which have come down to us in great numbers and are preserved chiefly at Vienna, Munich and Dresden. A fine collection of them was published lately in Corrado Ricci's, *I. Bibiena* (1915).

BIBIRINE or **BEBEERINE**, an alkaloid obtained from the bark and fruit of the greenheart (q.v.) tree, *Nectandra rodiaei*, called *bibiru* or *sipiri* in Guiana. It has been used as a febrifuge in place of quinine. Its formula is $C_{19}H_{21}NO_3$.

BIBLE. The English word "Bible" is derived through Mediaeval Latin from the Greek *τὰ βιβλία*, which simply means "the books." It is the name given to the collection of books which Christian people regard as sacred and in which they find the record of the revelation that lies at the basis of their faith

INTRODUCTION

This article will deal with the collection as a whole. It will fall into two main sections, Old Testament and New Testament, and each section will treat of such topics as the Canon, Texts and Versions, Textual Criticism, Higher and Historical Criticism, and Chronology. But such an article may suitably be prefaced

by some account of the conceptions which men in the past have formed of these books, and by some consideration of the characteristics which from age to age have impelled men to regard them as sacred or which have been attributed to them because they were sacred. For the special problems presented by the individual books of the Bible and for a discussion of the historical origin and nature of each, the relevant separate articles should be consulted. For the English versions of the Bible, see **BIBLE, ENGLISH.**

To the first Christians, who were Jews, the law and the Prophets were already sacred. Their national sacred writings were to them the oracles of God, though they could no longer be regarded as containing the whole truth of God. The coming of the Messiah had revealed God with a completeness that could not be discovered in the Old Testament. The word of the Lord was authoritative as even Moses and the prophets were not. Yet since all the hopes of the Old Testament seemed to these Jewish Christians to be fulfilled in Jesus Christ, they more than ever were convinced that their national sacred books were divinely inspired. From this source they drew, if not the articles of their creed, at least the proofs and supports of their doctrines. Christ died and rose again, according to the scriptures. All the writings of the Old Testament spoke of Christ to them. Legal enactment, prophetic utterance, simple historical record, and more emotional psalm,—all alike could be covered by the phrase "the scripture says," all were treated as of one piece, and by diligent use of type and allegory single passages torn from any context could be used as proof-texts to commend or defend belief in Christ.

It is not strange that Jewish Christians claimed the Old Testament as their book and found in it the confirmation of their faith. It is more remarkable that the Old Testament in its Greek dress appealed to the Gentile world and became a valued weapon in the armoury of the Christian evangelist. It was not on account of any literary charm of the Greek version. Educated readers were offended by the poor style of the Septuagint. But a passage from Tatian, a second century Apologist, may serve to show how this very poverty of style sometimes proved arresting. "When I was giving my most earnest attention to discover the truth, I happened to meet with certain barbaric writings, too old to be compared with the opinions of the Greeks, and too divine to be compared with their errors and I was led to put faith in these by the unpretending cast of the language, the inartificial character of the writers, the foreknowledge displayed of future events, the excellent quality of the precepts and the declaration of the government of the Universe as centred in one Being." (Tatian, *Address to the Greeks*, 29.)

Evidently non-Jews were impressed by the supposed antiquity of the Hebrew scriptures and by the simplicity and directness of the teaching of the prophets. To philosophers weary of the discussions of the schools the Church offered in the Old Testament, with its note of assurance and absence of logical argument, that divine word which Plato desired as a surer and safer guide through life than human reason. The elaborate argument from prophecy to which the Church attached so much weight, convinced Gentiles as well as Jews; indeed it convinced Gentiles rather than Jews. Moreover men appreciated the moral insight of the prophets. Their oracles were not only less ambiguous but also more ethical than those of Delphi. And then there was the uncompromising monotheism of Israel and the doctrine of Creation. The opening chapter of Genesis won men to Christ, because it declared the government of the Universe to centre in one Being.

When, towards the close of the second century, the collection of apostolic writings was associated with the Old Testament, and the Bible was practically complete (see below, **NEW TESTAMENT, I. CANON**), the Church could point enquirers to a number of books originally composed in Greek. But even so, the style of an evangelist like Mark offended the taste of educated readers, and the letters of St. Paul are not literature when judged by the standards of the age. When Celsus urges that truths taught in the gospels are expressed much better in the language of Plato, Origen does not deny the literary advantage of Plato, but claims that the simplicity of the scriptures appeals to the multitude

In the characteristics which offended literary taste, Origen saw the proof that God had chosen the foolish things of this world to confound the wise. He makes much of the argument from prophecy, but stresses most the fact that "men of all nations have deserted the laws of their fathers and the established gods, for the observation of the laws of Moses and the discipleship of the words of Jesus Christ." He states very clearly the direct appeal of many parts of the scripture to men's conscience. "He who reads the words of the prophets with care and attention, feeling by the very perusal the traces of the divinity that is in them, will be led by his own emotions to believe that those words which have been deemed to be the words of God are not the compositions of men." (*De Princ.* iv. 1 and 6.)

Once the Bible was in being, Christians naturally attributed to the Bible as a whole the characteristics which the Jews had attributed to the Old Testament. According to Philo, all that the scriptures contain is true, and all truth is contained in them. It was easier for the Christians to assert this of the Bible than for Philo to assert it of the Law. But this assertion compelled Christian theologians to adopt Philo's method of dealing with difficult passages. Origen could see that there were passages, particularly in the Old Testament, but also in the gospels, that were not true in their literal sense. He could see that some passages were morally perplexing, and indeed indefensible on any Christian standard. The difficulty thus presented he surmounted by Philo's method of allegory. Where the literal sense of the scriptures is obscure, or untrue, or immoral, deeper meanings must await discovery. So he found a three-fold sense in scripture. For the most part, the literal sense is edifying and will appeal to all. But it is legitimate everywhere to look for secondary meanings, and in some passages it is imperative to do this, since only in this way can scripture be harmonized with itself. It was assumed that there could be no real contradictions in scripture. The sense of the fundamental harmony of the Old and New Testaments was expressed in Augustine's aphorism, "The New Testament lies hid in the Old, and the Old Testament is manifested in the New." Most Christians took over the view of inspiration accepted by Philo and Josephus, which regards the prophet or writer as a passive instrument in the hands of God. Some of the Fathers, such as Gregory of Nazianzus, perceived that divine inspiration did not override the personality of prophet or evangelist, but the Church in general tended to accept the ecstatic view of prophecy and the mechanical conception of inspiration. It is worth noting that the ancient Catholic Church encouraged Bible-reading, and that the Bible was early accessible in Syriac and Latin for those who did not read Greek. Harnack writes: "The Church was compelled to lay stress on Bible-reading because, according to her doctrine, souls could be lost through want of knowledge, and so she became the great elementary school mistress of the Greeks and Romans." (*Bible Reading in Early Ch.* p. 85.)

While the ancient Church up to the fall of the Roman Empire in the West encouraged Bible-reading, Christianity did not become simply the religion of a book. The baptismal confession of faith was attributed to the apostles as definitely as the New Testament itself, and when the claims of heretics to possess esoteric apostolic traditions had been refuted, the Church did not hesitate to assert apostolic sanction for traditions and usages that could not be directly traced in the apostolic writings. Consequently for the mediaeval Church the scriptures are still the final authority, but they are associated closely with ecclesiastical tradition, and this complex is assumed to represent the minds of the apostles. For St. Thomas Aquinas, the authority of the Church, both in its teaching and in its practice, cannot be distinguished from the authority of scripture. "In spite of the very explicit assignment of the sole ultimate authority to the scriptures, and the recognition of the duty of the theologian to bring all his teaching to the test of scripture and be content to rest upon no lower grade of assurance, we feel ourselves from the very first guided in our interpretation of scripture by an invisible hand, and referred to clauses of the creeds, to verses in the liturgy or to decrees of councils as though they were final authorities." Aquinas was able to harmonize scripture and Church tradition because he had at his disposal the methods of

scripture interpretation that the scholastics took over from the Fathers, particularly from Origen and Augustine. Once again the allegorical method saved the situation. Positively the claim of the Christian scriptures to be a divine revelation rests for Aquinas on two elements: the element of miracle and the wide appeal of the truths contained therein. Miracle and prophecy and the power of inspiring a faith that triumphs over death are the main proofs of the divine origin of the scriptures.

The circumstances of the Dark Ages made a breach in the earlier habits of Bible-reading among the laity, and it was not till towards the close of the 12th century that the situation began to change. Perhaps the superstitious use of the scriptures to provide amulets and omens—a tendency that began early and grew more intense in the Dark Ages—may have inclined the Church to withhold the Bible from the laity. However that may be, when popular interest in the scriptures revived, the Church felt apprehensive because Bible-reading led to heresy. As men became acquainted once again with the text of the scriptures, they inevitably realized that the harmony which Aquinas assumed between the teaching of scripture and Church tradition was not obvious or complete. In the work of a commentator like Lyra, the traditional methods of interpretation were challenged by insistence on the literal meaning of the scriptures as fundamentally important. The Reformation detached the scriptures from the Church tradition, and permitted the plain sense of the scriptures to make a direct appeal to the common people.

The great Reformers held that all truths necessary for salvation were to be found in the scriptures and were to be found so plainly expressed that the ordinary devout reader could discover them for himself. They dwelt much on the sufficiency and perspicuity of the scriptures. Difficulties remained and perhaps would always remain, to exercise men's faith, but normally scripture was its own interpreter and light on its dark places could be derived from the texts whose meaning was clear. In exalting the scriptures over against Mediaeval Church tradition, the followers of the great Reformers assumed the perfection of the scriptures. The Bible was the source of guidance and enlightenment in every department of human life and thought. The Puritans tended to push the claim so far as to insist that no action in daily life could be regarded as righteous unless expressly warranted by Holy Writ. Whatsoever is not of faith is sin, and faith is not, save where there is an appeal to the word of God, and the word of God is the scripture.

Over against this extreme, Hooker advocated the claim of reason to be a God-given guide and defended the Anglican principle that Christians do not always need positive assurance from the scriptures for any given Church-rite or individual action, though they must never contravene scripture in the name of reason. George Fox and the Quakers urged that inspiration was not confined to the scriptures. The spirit of Christ still guided men, and though His guidance would not be contrary to the essential life of the scriptures, yet it might be given apart from the scriptures and would take men beyond the letter of the scriptures. But the main current of religious thought in England in the 17th century and later in the Evangelical revival endorsed the Puritan estimate of the Bible. The influence of the Bible was thus carried into the heart of English life and literature, but it was accompanied by the moral dangers of Bibliolatry. Scripture had still to be harmonised with itself, and this was the more difficult since symbolic interpretations were to be abandoned. Forced exegesis was constantly resorted to, both to defend the inerrancy and authority of the scriptures themselves and to secure Biblical authority for the tenets and practices of particular churches and individuals. Yet through it all, the case for the authority and inspiration of the scriptures is based broadly on the same grounds as in the days of the Apologists. Thus, Whitaker, the Elizabethan divine, summarizes the evidence for inspiration under eight heads: "(1) The majesty of the doctrine itself; (2) the simplicity, purity and divinity of the style; (3) the antiquity of the books themselves (the books of Moses are more ancient than the writings of any other men); (4) prophetic oracles; (5) miracles; (6) the failure of enemies to destroy them; (7) the testimony of martyrs, and (8) the character of the writers, mostly illiterate and inca-

FRAGMENTS FROM GREEK AND SYRIAC BIBLES OF THE 4TH TO THE 12TH CENTURY

1. 3rd century papyrus fragment, Greek: Matt. i. 1-8. 2. Codex Vaticanus, Greek, 4th century: Mark xiii. 5-8. 3. Codex Sinaiticus, Greek, 4th century: Matt. xv. 21-22. 4. Codex Alexandrinus, Greek, 5th century: Acts xxiii. 23-27. 5. Codex Bezae, Greek, 4th-5th century: Luke vi. 1-10, with interpolation. 6. Codex Purpureus, Greek, 6th century: John xv. 17-18. 7. Washington (Freer) ms., Greek, 5th century: Interpolation after Mark xvi. 14-20. 8. Codex Theodora Imperatricis, Greek, 9th century: Luke i. 28-32. 9. Koridethi ms., Greek, 7th-9th century: Mark xii. 43 to xiii. 5. 10. Greek, 11th-12th century: Luke ix. 48-54. 11. Codex Palimpsestus Sinaiticus, Old Syriac version 4th century, upper writing 8th century: Luke xix. 39-45

pable of writing without inspiration." John Owen, Vice-Chancellor of Oxford in the time of the Commonwealth, who makes the strongest claims for the infallible authority of the scriptures is somewhat more discriminating in stating the grounds of his faith. He does not think that the evidence of miracles counts for much, and he holds that the authority of scripture must rest on its self-evidencing light and power.

Many difficulties of the Puritan view of the scriptures arose from the unsolved problem of harmonizing the contents of a literature whose production extends over a thousand years, when once the methods of interpretation adopted by the Fathers and the Schoolmen were surrendered. But more serious questions were precipitated by developments of natural science and by the progress of literary and historical criticism. Even before the advent of Copernicus, Colet saw that the story of creation could not be harmonized with natural science, and the work of Copernicus and Galileo brought men face to face with the actual limitations of the knowledge of Biblical writers. It was becoming apparent that not all truth is contained in the scriptures and not all that the scriptures contain is true. This problem of a conflict between the contents of the Bible and the findings of natural science has been intensified by every advance of science, and reached an acute stage in the work of Darwin. Men's reactions to this problem have varied. Those who suppose that the authority of the Bible depends on its inerrancy have tended to become either obscurantists or rationalistic agnostics. Those who reject this supposition have often restricted the sphere of the Bible to faith and morals, and have assumed with Spinoza that it has no ultimate authority in the realm of natural science, or of historical enquiry, or of philosophic speculation. The Bible is not intended to teach science or history: it is to guide men in faith and conduct. This attempted solution is expressly rejected in the Encyclical Letter *Providentissimus Deus* of Leo XIII. "For the system of those who, in order to rid themselves of these difficulties, do not hesitate to concede that divine inspiration regards the things of faith and morals and nothing beyond, because (as they wrongly think) in a question of the truth or falsehood of a passage, we should consider not so much what God has said as the reason and purpose which He had in mind in saying it—this system cannot be tolerated." "It is absolutely wrong and forbidden, either to narrow inspiration to certain parts only of Holy Scripture or to admit that the sacred writer has erred." The position thus defined by the Pope is still the position adopted by a large number of Protestants.

Side by side with the advance of natural science came the development of literary and historical scholarship, and the demand that the Bible should be read and studied like any other book. This meant not that the Bible was the same in character as any other book, but that the same canons of criticism must be applied to the national literature of the Hebrews and the writings of the first Christians as were applied to the literature and history of other people or to the classical documents of other faiths. "The study of Hebrew and Greek texts dissolved at last the cement by which the doctrine of Inspiration had held together the whole Bible as a homogeneous Divine product." The discrepancies and disharmonies in the scriptures could no longer be disguised. Moreover many traditional beliefs concerning the date and authorship of particular books were found to have no support in the text of the Bible itself. Thomas Hobbes had observed that the Pentateuch seems to be written *about* Moses rather than *by* Moses. Literary criticism showed that the Mosaic authorship of the Pentateuch was a Rabbinic tradition, which was unsupported by the Pentateuch.

The net effect of the progress of natural science and literary criticism was to undermine the claims made for the scriptures on the grounds of their alleged antiquity and absolute harmony. The traditional arguments from prophecy ceased to carry weight, and the appeal to miracles was discounted. The fundamental argument for regarding the scriptures as sacred and inspired remained untouched. Coleridge restated this essential argument in his *Confessions of an Enquiring Spirit*, where he urged that "whatever finds me, bears witness for itself that it has proceeded from a Holy Spirit." But the significance of his confession lies in his

realization that this evidence for inspiration does not confirm the traditional ideas of verbal inspiration and complete inerrancy. Indeed he felt that to attribute equal value to all the contents of the Bible is to falsify the findings of the conscience of its readers. The propositions, "The Bible contains the religion revealed by God" and "Whatever is contained in the Bible is religion and was revealed by God," are not interchangeable.

The characteristics of the Bible emphasized in modern study are briefly these: First, its popular character and appeal, admitted by the early Fathers and asserted by the Reformers, have been confirmed by modern research. Thus, the Greek of the New Testament has been shown to be the language in every-day use in the Roman Empire in the first century A.D. Secondly, the literary charm of the Bible is in the main a modern discovery. Tindal perceived that the Hebrew of the Old Testament would go much better into English than into Latin or Greek, and certainly the Old Testament in the Septuagint or the Vulgate made little appeal to men of taste. In England, through the authorized version, Hebrew literary genius has exerted a healthy influence both on language and literature. Thirdly, the Bible is at length discovered to be, not a manual of theology, but the record of a varied and developing religious experience. In it religion is presented, not in an abstract and dogmatic form, but in concrete historical embodiments. It thus becomes the guide and inspiration of personal religion. Fourthly, the Bible is contrasted with a book like the Koran, inasmuch as the Koran represents a revelation to a single prophet, while the Bible contains writings ranging from the Hebrew monarchy to A.D. 100, contributes to the true understanding of a series of uniquely vital centuries in human history, and exhibits a variety of experience combined with the real unity of a genuine development. Thus, historical criticism suggests the idea of progressive revelation and outlines the steps of the actual progress. Fifthly and lastly, the permanent and unique value of the Bible is now seen to depend, not on any miracle attending its composition, not on any form of inspiration confined to Biblical writers, but simply on the unique phenomenon of Hebrew prophecy and its culmination in the life and teaching of Jesus. So long as men recognize the distinctive character of Hebrew prophecy or so long as they respond to the influence of Jesus, the volume which contains the history of His people and their preparation for His coming, together with the memories, impressions and reflections of His first disciples, must retain in their hearts and thoughts a place no other book can claim or fill.

OLD TESTAMENT

1. CANON

There exists no historical account of the formation of the Old Testament canon. The popular idea that it was closed by Ezra rests on no ancient foundation. Certainly in 2 Esdras (near the end of the 1st century A.D.), we read (xiv. 20–26, xxxviii–xlvi), that the law being burnt, Ezra, at his own request, was inspired to rewrite it; in forty days he dictated 94 books to five scribes, *i.e.*, the 24 books of the Old Testament and 70 apocryphal books, filled with esoteric wisdom and superior to the Old Testament. This worthless legend contains nothing about a completion of the Canon or collection or redaction of sacred books; yet patristic writers infer from it that Ezra restored the lost Old Testament books. The reference to the library of Nehemiah in 2 Macc. ii. 13 is found in a late and untrustworthy section of the book and nothing definite can be built upon it.

The modern idea that the Old Testament canon was closed by Ezra is not found before the thirteenth century A.D. From this time the legend grew, until with Elias Levita (1538), and especially Johannes Buxtorf (1665), it assumed the form that the "men of the Great Synagogue"—a body of very dubious historicity—with

Ezra as president, collected the books, restored the text and made the threefold division. Through their reputation this view acquired general currency, but it rests on no authority in antiquity whatever.

In the Jewish canon the books are divided into three parts. "The Law, the Prophets and the Writings, *i.e.*, the Hagiographa," is the standing Jewish expression for the Old Testament, and the books are arranged in the following three divisions:

1. The Torah (or "Law"), *i.e.*, our "Pentateuch" (5 books).
2. The "Prophets" (8 books) in two groups: (a) The "Former Prophets"; Joshua, Judges, Samuel, Kings; (b) The "Latter Prophets," Isaiah, Jeremiah, Ezekiel, the "Minor Prophets" (called "The Twelve," and counted as *one* book).
3. The "Writings" (or the "Sacred Writings" *i.e.*, the "Hagiographa"), consisting of three groups (11 books): (a) the poetical books, Psalms, Proverbs, Job; (b) The five Megilloth (or "Rolls")—read in the synagogues at five sacred seasons—Song of Songs, Ruth, Lamentations, Ecclesiastes, Esther; (c) The remaining books, Daniel, Ezra and Nehemiah (forming *one* book), Chronicles. The 24 books of the Hebrew Canon have become 39, as in the English Bible, by treating each of the Minor Prophets as a separate book, by separating Ezra from Nehemiah and subdividing Samuel, Kings and Chronicles. When the Greek translation was made between the third and first centuries B.C., the books were regrouped, mostly by subjects, in the order history, poetry, prophecy, the Apocrypha being included and its books being placed in the appropriate classes. Substantially the same order was followed in the Vulgate. The reformers placed the Apocrypha at the end; the remaining books, as they stood in the Vulgate, were then in the order which they retain in the English Bible.

The tripartite division was far earlier than the Talmud. The Proverbs of Jesus, the son of Sirach (c. 200 B.C.), now known as Ben Sira or Ecclesiasticus, were translated into Greek by his grandson about 130 B.C. He speaks of "the law, and the prophets, and the other books of our fathers," and of the law, and the prophets, and the rest of the books (*cf.* the Law, the Prophets and the Psalms, Luke xxiv. 44). See also Dan. ix. 2 (R.V.), written c. 165 B.C. This threefold division represents three successive stages in the history of the collection. The Law was the first part to be definitely recognised as authoritative, or canonised; then the Prophets ("Former" and "Latter"); lastly the Hagiographa. In the absence of external evidence we must fix the dates by internal evidence. This points to the conclusion that the Law was not completed and accepted as canonical before 444 B.C. (*cf.* Neh. viii.-x.); that the prophets were completed and recognised about 250-200 B.C.; and the Hagiographa between about 150 and 100 B.C.

We must now sketch the process by which the Old Testament reached its completed form. It is characteristic of nearly all the longer books and some of the shorter that they were not completed by a single hand, but were gradually expanded and reached their present form by stages.

The earliest beginnings of Hebrew literature were probably poetical. Great national occurrences and the deeds of ancient heroes stimulated the national genius for poetry and evoked lyric songs, suffused with religious feeling, by which their memory was perpetuated. Illustrations may be found in the opening of the Song of Moses in Ex. xv.; Song of Deborah (Judges v.), the extracts from the "Book of Jashar" (or "of the Upright," *i.e.*, Israel), see Josh. x. 12, 13, II. Sam. i. and probably I. Kings viii. 13 (Sept. 53) in the Septuagint; and in the fragment from "the Book of the Wars of Yahweh" (Num. xxi. 14, 15); the war ballad in Num. xxi. 27-30. To these may be added the Blessings of Jacob (Gen. xlix.) and Moses (Deut. xxxiii.). These poems are in most cases considerably older than the narratives in which they are embedded.

The historical books form two series: one, consisting of the books from Genesis to II Kings (exclusive of Ruth which belongs to the Hagiographa) embracing the period from the Creation to the destruction of Jerusalem in 586 B.C.; the other, comprising Chronicles, Ezra and Nehemiah, beginning with Adam and ending with Nehemiah's second visit to Jerusalem in 432 B.C. These, while differing in scope and point of view, are both constructed on

a similar plan. Older writings have been combined by a compiler, or a succession of compilers, so that the points of juncture are often discernible and the sources can be disentangled. The authors of the historical books in their present form do not, as a rule, *rewrite* the matter in their own language; they *excerpt* from pre-existing documents such passages as are suitable to their purpose and incorporate them in their work, sometimes adding matter of their own. The sources thus combined can generally be distinguished by strongly marked individualities of style from each other and from additions of the compiler. The literary differences are often accompanied by differences of treatment, or representations of the history, which confirm independently the conclusions of the literary analysis. Sometimes the excerpts form long complete narratives; in other cases they consist of short passages taken alternatively from two older narratives and dovetailed together to make a continuous story. The compiler of Judges and Kings has arranged older narratives in a framework of his own; the literary structure of the Hexateuch, *i.e.*, the Pentateuch and the Book of Joshua, is more complex.

The Hexateuch.—The Hebrew traditions respecting Israel's origins and early history were probably first cast into a written form in the 10th or 9th century B.C. by a prophet living in Judah, who, from the almost exclusive use in his narrative of the sacred name Yahweh (*see* JEHOVAH), is referred to by the abbreviation J. This writer, who is characterised by a singularly bright and picturesque style, and also by deep religious feeling and insight, relates man's creation from the dust, his first sin and its consequences (Gen. ii. 4b-iii. 24); then he gives an account of the early growth of civilisation (Gen. iv.), of the Flood (parts of Gen. vi.-viii.), and the origin of different languages xi. 1-9; afterwards in a series of vivid pictures he gives the story, as tradition told it, of the Patriarchs, of Moses and the Exodus, of the journey through the wilderness and the conquest of Canaan. Examples of J's narrative (including here or there verses taken from another document), may be found in Gen. xii, xliii., xviii.-xix., xxiv., xxvii. 1-45, xxxii., xliii., xlv.; Ex. iv.-v. (mostly), viii. 20-ix. 7, x. 1-xi., xxxiii. 12-xxxiv. 26; Num. x. 29-36, and most of Num. xi.

Somewhat later than J, another writer, commonly referred to as E, from his preference for the name *Elohim* ("God") rather than "Yahweh," living apparently in the Northern Kingdom, wrote down the traditions as they were current in Northern Israel, in a style resembling that of "J," but not quite as bright and vivid, and marked by small differences of expression and representation. The first traces of "E" are found in the life of Abraham, in parts of Gen. xv. Examples of other passages belonging to E are Gen. xx. 1-17, xxi. 8-32, xxii. 1-14, xl.-xlii. and xlv. (except a few isolated passages); Ex. xviii. 20-23 (including the Decalogue—in its original terser form, without the explanatory additions—and the collection of laws, known as the "Book of the Covenant," in xxi.-xxiii.), xxxii., xxxiii. 7-11; Num. xii., most of Num. xxii.-xxiv.; Josh. xxiv. E thus covers substantially the same ground as J, and often gives a parallel, though somewhat divergent, account of the same events. The laws in the Book of the Covenant were no doubt taken from a pre-existing source; with J's regulations in Ex. xxxiv. 17-26, they form the oldest legislation of the Hebrews that we possess; they consist principally of civil ordinances, suited to regulate the life of the community living under simple traditions of society, and chiefly occupied in agriculture, but partly also of elementary regulations respecting religious observances (altars, sacrifices, festivals, etc.).

Not long, probably, after the fall of the Northern Kingdom in 722 B.C., a prophet of Judah selected extracts from J and E and combined them with additions of his own in a single narrative (JE). As distinguished from the priestly narrative (*see* below), it has a distinctly prophetic character; it treats the history from the standpoint of the prophets and their religious ideas often find expression in it. To it belong most of the best-known narratives of the patriarchal and Mosaic ages. Its style, especially in the parts belonging to J, is graphic and picturesque, the descriptions are vivid and abound in detail and colloquy, and both emotion and religious feeling are warmly and sympathetically expressed in its relation.

Deuteronomy.—Probably in the 7th century during the reign of either Manasseh or Josiah the narrative of JE was enlarged by the addition of the discourses of Deuteronomy. These purport to be addresses delivered by Moses to the people shortly before his death. There was probably some tradition of such a farewell address. In strong and persuasive oratory he sets before Israel, in a form adapted to the needs of the age in which he lived, the fundamental principles of Moses. Yahweh was Israel's only God, who tolerated no other God beside Himself, and who claimed to be the sole object of the Israelites' reverence. This fundamental thought is insisted on and developed with great eloquence and power. The truths on which the writer loves to dwell are the sole Godhead of Yahweh, His spirituality, His choice of Israel, and the love and faithfulness which He had shown towards it by redeeming it from slavery and planting it in a free and fertile land; from which are deduced the great practical duties of loyal and loving devotion to Him, an uncompromising repudiation of all false gods, the rejection of all heathen practices, a cheerful and ready obedience to His will and a warm-hearted and generous attitude towards man. Love of God is the primary spring of human duty (vi. 5). In ch. xii.-xxvi. the author embodies most of the laws incorporated in JE, with many others which were current, often expanding them and enforcing them by moral and religious motives. His ideal is a community of which every member is full of love and reverence towards his God, and of sympathy and regard for his fellow men. The "Song" (xxxii.) and "Blessing" (xxxiii.) of Moses are not by the author of the discourses; and the "Blessing," though not Mosaic, is of considerably earlier date.

The influence of Deuteronomy on the later literature was great. It gave the religious ideals of the age, and moulded the phraseology in which these ideals were expressed. Its style lent itself readily to imitation; and a school of writers imbued with its spirit, and using its expressions, quickly arose. Thus the "JE" sections in Joshua were considerably expanded by a Deuteronomic editor, whose additions generalise Joshua's successes and describe his conquest of Canaan as far more complete than the earlier narratives assert. The compilers of Judges and Kings are also strongly influenced by Deuteronomy. (See DEUTERONOMY.)

The priestly sections of the Hexateuch (known as "P") are later than "JE," and even than Deuteronomy. This is apparent—to mention but one feature—from their more complex ritual and hierarchical organisation. They are apparently the work of a school of priests, who, after the destruction of the temple, began to write down and codify the pre-exilic ceremonial regulations combining them with a narrative extending from the creation to the settlement in Canaan; and who completed their work during the century following the restoration in 537 B.C. Their chief object is to describe in detail the leading institutions of the theocracy (tabernacle, sacrifices, purification, etc.), which they refer to the Mosaic age. The history, except at important epochs, is briefly summarised. Statistical data (lists of names, genealogies, and precise chronological notes) are a conspicuous feature. But the legislation though written down in or after the Exile was not the creation of that period. Many elements were of great antiquity as is clear from the older literature; it is based on pre-exilic temple usage, though in some respects a development of it, and exhibits the form which the older institutions ultimately assumed. In "P's" picture of the Mosaic age there are many ideal elements; it represents the priestly ideal of the past rather than the past as it actually was. Its style is strongly marked, numerous expressions not found elsewhere in the Hexateuch occur in it repeatedly. The following examples of passages from P will illustrate what has been said: Gen. i. 1-ii. 4a, xvii., xxiii., xxv. 7-17, xlv. 6-27; Ex. vi. 2-vii. 13, xxv.-xxxi., xxxv.-xl.; Lev. i.-xvi., xxvii.; Num. i. 1-x. 28, xv., xviii., xix., xxvi.-xxx., xxxiii.-xxxvi.; Josh. v. 10-12, the greater part of xv.-xix., xxi. 1-42. The section Lev. xvii.-xxvi. has a character of its own; it consists of a substratum of older laws, partly moral (xviii.-xx. mostly), partly ceremonial. It exhibits very marked characteristics, from one of which it has received the name of the Law of Holiness. These laws have been combined with elements belonging to, or conceived in the spirit of, the main body of P. Not long after "P" was completed, probably in the 5th

century B.C., the whole, consisting of "JE" and Deuteronomy, was combined with it; and the existing Hexateuch was thus produced.

For a detailed discussion of the remaining books of the Old Testament reference must be made to the relevant articles. Here some general observations must suffice. Judges consists substantially of older narratives arranged together not earlier than c. 600 B.C. by a compiler in harmony with a theory of the religious history of the period derived from Deuteronomy, and provided by him, where he deemed it necessary, with introductory and concluding comments and chronological notes. The books of Samuel consist of a series of narratives dealing with the lives of Samuel, Saul and David, some apparently almost contemporary with the events they describe, while others are later. We have two different views of the monarchy in I. Sam., in ix. 1-x. 16, xi. 1-11, 15, it is viewed as God's gracious gift to His people; in viii., x. 17-27, xii. which reflect the feeling of a much later date, it is viewed unfavourably and represented as granted by God unwillingly. Kings resembles Judges in its structure. Prophetic narratives and notices derived from official annals have been placed in a framework by the compiler who was greatly influenced by Deuteronomy, especially with reference to worship at the high places or local sanctuaries.

The Latter Prophets.—Isaiah, Jeremiah, Ezekiel, the Twelve. The activity of the Prophets was largely called for by national crises. They were moral reformers, religious teachers, political advisers. They held up before a backsliding people the ideals of human duty, religious truth and national policy. They expanded and developed, and applied to new situations, the truths which in a germinal form they had inherited. The nature and attributes of God; His gracious purposes towards man; man's relation to God and the consequences it involves; the true nature of religious service; the call to repentance as a condition of God's favour; the ideal of character and action which each should strive to realize; the responsibilities of office and position; the claims of mercy and philanthropy, justice and integrity; indignation against the oppression of the weak and the unprotected; ideals of a blissful future, when the troubles of the present will be over, and men will bask in the enjoyment of righteousness and felicity—these, and such as these, are the themes which are ever in the prophets' mouths and on which they enlarge with unwearied eloquence and power.

Isaiah.—This book falls into two parts i.-xxxix. and xl.-lxvi. In the former it is generally admitted that xiii. 1-xiv. 23, xxi. 1-10, xxiv.-xxvii., xxxiv.-xxxv. are later than Isaiah; and several critics would considerably enlarge the area of non-Isaianic material. The latter falls into two divisions (a) xl.-lv. and (b) lvi.-lxvi. The former is the work of a prophet (the Second Isaiah) who wrote about 540 B.C., assuring the exiles that Cyrus would overthrow Babylon and restore them to their own land. Opinion is divided as to whether the poems on "The Servant of Yahweh" are to be assigned to him or to another prophet. In lvi.-lxvi. we have a number of oracles, written probably about the time of Nehemiah, possibly the work of one man, but probably of more than one.

Jeremiah.—Jeremiah received his call in 626 B.C., and his latest prophecy (xlv.) was delivered in Egypt soon after the Fall of Jerusalem in 586. His was a sensitive and tender nature; he laments with great pathos and emotion his people's sins, the ruin to which his country was hastening and the persecutions provoked by his predictions of disaster. The biographical narratives were probably written by Baruch, who also wrote in 604 B.C. at the prophet's dictation the prophecies delivered from the time of his call. But the book was certainly not compiled in its present form by Baruch; and it contains a certain amount of later matter, though much less than some recent scholars (e.g., N. Schmidt, Duhm and Holscher) have asserted.

Ezekiel.—Ezekiel taken captive to Babylonia with Jehoiachin in 597 began his ministry in 592. He denounced the sin of Judah and steadily predicted the Fall of Jerusalem which took place in 586 (1-xxiv.). Prophecies on foreign nations follow in xxv.-xxxii.; and the book closes with prophecies of restoration (xxxiii.-xlvi.). In xl.-xlvi. he describes minutely the organisation of the restored community. His book has generally been thought to bear throughout the stamp of a single mind; but recently this has been denied, especially by Holscher, who regards the book as

for the most part of a later date, but probably without justification.

The Twelve Prophets.—The two earliest, Amos and Hosea, prophesied in the Northern Kingdom about 760 and 740 B.C. respectively. The former the prophet of God's inexorable righteousness, the latter the prophet of His inexhaustible love, saw the approaching ruin of Northern Israel and vainly exhorted the nation to reform. Approximate dates may be assigned to the other Minor Prophets as follows: Micah 725–680, Zephaniah 625; Nahum shortly before the destruction of Nineveh in 612; Haggai 520; Zechariah i.–viii. 520 and 518; Malachi 460–450; Joel 5th century; Jonah 4th century. The date of Habakkuk is very uncertain; it has generally, but perhaps wrongly, been assigned to the reign of Jehoiakim. Obadiah was written in its present form after the destruction of Jerusalem, but its relation with Jer. xlix. 7–22 raises complex problems. Zech. ix.–xiv. perhaps belongs to the period beginning with the conquests of Alexander, between 332 and c. 300 B.C.

The Psalms.—In the Psalter devotion receives its fullest expression; in lyrics of exquisite tenderness and beauty the most varied emotions find utterance—despondency and distress, penitence and resignation, hope and confidence, jubilation and thankfulness, adoration and praise. The Psalter is composed of five books all compiled after the return from captivity. Independent collections have been incorporated in it. It is an exaggeration to say that there are no pre-exilic Psalms; yet the Psalter, as a whole, is the expression of the deeper spiritual feeling which marked the later stages of Israel's history. Most of the Psalms presuppose the historical conditions, or the religious experiences, of the ages that followed Jeremiah. Its compilation can hardly have been completed before the 3rd century B.C.; if, as is probable, it contains Psalms of the Maccabean period, it cannot have been completed till after 165 B.C.

The Book of Proverbs.—The Wisdom-books of the Old Testament are Proverbs, Job and Ecclesiastes. The wisdom of the Hebrews dealt with the philosophy of human nature, sometimes also of physical nature; its writers observed human character, studied action in its consequences, laid down maxims for education and conduct, and reflected on the moral problems which human society presents. The book which consists of eight distinct portions was formed gradually. A small nucleus of the Proverbs may be Solomon's, but the great majority no doubt represent the generalisations of a long succession of sages. The book will not have reached its present form before the 4th century B.C. But recent discovery of Egyptian parallels to one section of the book suggests that a considerably larger section of it may be pre-exilic than has often been supposed.

Job.—The outline of the story was probably borrowed from tradition; but the poet has used it as a vehicle for expressing his own new thoughts on the suffering of the righteous and the prosperity of the wicked, and especially to indicate the sufferer's own reaction to his trial as it affected his relation to God. The speeches of Elihu are a later insertion; but the prologue, epilogue and the speech of Yahweh are probably integral parts of the original work. Its date may most plausibly be assigned to about the close of the 5th century.

The Megilloth.—The five Megilloth or rolls are the Song of Songs, Ruth, Lamentations, Ecclesiastes and Esther. The Song of Songs (*see* CANTICLES) in exquisite poetry extols the power and sweetness of pure and faithful human love. In spite of features which suggest that it was written in North Israel at an early date, it is probably as late as the 4th or 3rd century B.C. The view that it contains the story of a country maiden who remains true to her rustic lover in spite of the blandishments of Solomon should probably be set aside. It seems to be a collection of wedding songs. The graceful and tender idyll of Ruth probably belongs to the 5th century. The Lamentations were written after the Fall of Jerusalem, the second and fourth soon after the catastrophe, the first and fifth presumably nearer the end of the exile, while the third is perhaps post-exilic. It is unlikely that any of them were composed by Jeremiah. Ecclesiastes must be one of the latest books in the Hebrew Canon, written probably towards the end of the

3rd century. Its tender-hearted author is in despair as he contemplates the futility of existence and the misery of his fellows. Progress is impossible, God has deliberately concealed from men the real scheme of things knowing which they could have ordered their lives aright; nor from the present can we take refuge in the future and hope for a blessed immortality. The Book of Esther will not be earlier than the 3rd century B.C., it is not improbable indeed that it belongs to the latter half of the 2nd century.

The Book of Daniel.—This book was written to encourage the pious Jews in the persecution of Antiochus Epiphanes 168–165 B.C. It is possible that the narrative section ch. i.–vi. may belong to the 3rd century. Ch. vii.–ix. describe events from Alexander through the lines of the Ptolemies and the Seleucidae, culminating in the persecution of Antiochus Epiphanes and predicting his speedy fall.

Chronicles, Ezra and Nehemiah.—These books are the work of a single compiler who has drawn on canonical and uncanonical sources, sometimes without substantial change, sometimes with material alteration. His additions, especially in Chronicles, placed the old history in a new light; he invests it with the associations of his own day, and pictures pre-exilic Judah (of the schismatic Northern Kingdom he says very little) as already possessing the fully developed ceremonial system, under which he lived himself, and as ruled by the ideas and principles current among his contemporaries. Much in his representation of the past cannot be historical. From historical allusions in the Book of Nehemiah it may be inferred that he wrote about 300 B.C. (S. R. D.; A. S. P.)

2. TEXTS AND VERSIONS

Text.—The form in which the Hebrew text of the Old Testament is presented to us in all mss. and printed editions is that of the Massoretic text, the date of which is usually placed somewhere between the 6th and 8th centuries. It is probable that the present text became fixed as early as the 2nd century A.D., but even this earlier date leaves a long interval between the original autographs of the O.T. writers and our present text. Since the fixing of the Massoretic text the task of preserving and transmitting the sacred books has been carried out with the greatest care and fidelity, with the result that the text has undergone practically no change of any real importance; but before that date, owing to various causes, it is beyond dispute that a large number of corruptions were introduced into the Hebrew text.

Massoretic Text.—An examination of the extant mss. of the Hebrew O.T. reveals two facts which at first sight are somewhat remarkable. The first is that the oldest dated ms., the *Codex Babylonicus Petropolitanus*, only goes back to the year A.D. 916, though it is probable that one or two mss. belong to the 9th century. The second fact is that all our Hebrew mss. represent one and the same text, viz., the Massoretic. This text was the work of a special guild of trained scholars whose aim was not only to preserve and transmit the consonantal text which had been handed down to them, but also to ensure its proper pronunciation. To this end they provided the text with a complete system of vowel points and accents. Their labours further included the compilation of a number of notes, to which the term *Massorah* is now usually applied. These notes for the most part constitute a sort of index of the peculiarities of the text, and possess but little general interest. More important are those passages in which the Massoretes have definitely adopted a variation from the consonantal text. But many even of these readings merely relate to variations of spelling, pronunciation or grammatical forms; others substitute a more decent expression for the coarser phrase of the text, though in some instances the suggested reading really affects the sense of the passage. These last are to be regarded either as old textual variants or, more probably, as emendations corresponding to the *errata* or *corrigenda* of a modern printed book. They do not point to any critical editing of the text; for the aim of the Massoretes was essentially conservative. Their object was not to create a new text, but rather to ensure the accurate transmission of the traditional text which they themselves had received. Their work may be said to culminate in the vocalized text which resulted from the labours of Rabbi Aaron ben

Asher in the 10th century. But the writings of Jerome in the 4th and of Origen in the 3rd century both testify to a Hebrew text practically identical with that of the Massoretes. Similar evidence is furnished by the Mishna and the Gemara, the Targums, and lastly by the Greek version of Aquila, which dates from the first half of the 2nd century A.D. Hence it is hardly doubtful that the form in which we now possess the Hebrew text was already fixed by the beginning of the 2nd century. On the other hand, evidence such as that of the Book of Jubilees shows that the form of the text still fluctuated considerably as late as the 1st century A.D., so that we are forced to place the fixing of the text some time between the fall of Jerusalem and the production of Aquila's version. Nor is the occasion far to seek. After the fall of Jerusalem the new system of biblical exegesis founded by Rabbi Hillel reached its climax at Jamnia under the famous Rabbi Aqiba (died c. 132). The latter's system of interpretation was based upon an extremely literal treatment of the text, according to which the smallest words or particles, and sometimes even the letters of scripture, were invested with Divine authority. The inevitable result of such a system must have been the fixing of an officially recognized text, which could scarcely have differed materially from that which was finally adopted by the Massoretes. That the standard edition was not the result of the critical investigation of existing materials may be assumed with some certainty. Indeed, it is probable, as has been suggested, that the ms. which was adopted as the standard text was an old and well-written copy, possibly one of those which were preserved in the Court of the Temple. (W. Robertson Smith, *Old Testament and the Jewish Church*, p. 69.)

It is, however, certain that before the 2nd century A.D. the various mss. of the O.T. differed very materially from one another. Sufficient proof of this statement is furnished by the Samaritan Pentateuch and the Versions, more especially the Septuagint. Indications also are not wanting in the Hebrew text itself to show that in earlier times the text was treated with considerable freedom. Thus, according to Jewish traditions, there are 18 passages ("corrections of the scribes"), in which the older scribes deliberately altered the text on the ground that the language employed was either irreverent or liable to misconception. Of a similar nature are the changes introduced into proper names; e.g., Ishbosheth (II. Sam. ii. 8) and Mephibosheth (II. Sam. ix. 6), for the older forms Eshbaal and Merib-baal (I. Chron. viii. 33, 34); the use of the verb, "to bless," in the sense of cursing (I. Kings xxi. 10, 13; Job i. 5, 11, ii. 5, 9; Ps. x. 3); and the insertion of "the enemies of" in I. Sam. xxv. 22, II. Sam. xii. 14. These intentional alterations, however, only affect a very limited portion of the text, and though it is possible that other changes were introduced at different times, it is very unlikely that they were either more extensive in range or more important in character. At the same time it is clear both from internal and external evidence that the archetype from which our mss. are descended was far from being a perfect representative of the original text. For a comparison of the different parallel passages which occur in the O.T. (e.g., I. and II. Sam., I. and II. Kings and I. and II. Chron.; II. Kings xviii. 13-xx. 19 and Isaiah xxxvi-xxxix; II. Sam. xxii. and Ps. xviii.; Ps. xiv. and liii., etc.) reveals many variations which are obviously due to textual corruption, while there are many passages which in their present form are either ungrammatical, or inconsistent with the context, or with other passages. Externally also the ancient versions, especially the Septuagint, frequently exhibit variations from the Hebrew which are not only intrinsically more probable, but often explain the difficulties presented by the Massoretic text. Our estimate of the value of these variant readings, moreover, is considerably heightened when we consider that the mss. on which the versions are based are older by several centuries than those from which the Massoretic text was derived; hence the text which they presuppose has no slight claim to be regarded as an important witness for the original Hebrew.

Versions.—In point of age the Samaritan Pentateuch furnishes the earliest external witness to the Hebrew text. It is not a version, but merely that text of the Pentateuch which has been

preserved by the Samaritan community since the time of Nehemiah (Neh. xiii. 23-31), i.e., about 432 B.C. It agrees with the Septuagint version in many passages, but its chief importance lies in the proof which it affords as to the substantial agreement of our present text of the Pentateuch, apart from certain intentional changes (e.g., Ex. xx. 17, 19 ff; Num. xx. f.; Deut. xxvii. 4), with that which was promulgated by Ezra. Its value for critical purposes is considerably discounted by the late date of the mss., upon which the printed text is based.

The Targums, or Aramaic paraphrases of the books of the O.T. (see TARGUM), date from the time when Hebrew had become superseded by Aramaic as the language spoken by the Jews, i.e., during the period immediately preceding the Christian era. In their written form, however, the earlier Targums, viz., those on the Pentateuch and the prophetic books, cannot be earlier than the 4th or 5th century A.D. Since they were designed to meet the needs of the people and had a directly edificatory aim, they are naturally characterized by expansion and paraphrase, and thus afford invaluable illustrations of the methods of Jewish interpretation and of the development of Jewish thought. The text which they exhibit is virtually identical with the Massoretic text.

The earliest among the versions as well as the most important for the textual criticism of the O.T. is the Septuagint (*q.v.*). This version probably arose out of the needs of the Greek-speaking Jews of Alexandria in the 3rd century B.C. The name Septuagint, strictly speaking, only applies to the translation of the Pentateuch, but it was afterwards extended to include the other books of the O.T. as they were translated. That the interval which elapsed before the Prophets and the Hagiographa were also translated was no great one is shown by the prologue to Ecclesiasticus, which speaks of "the Law, the Prophets and the rest of the books," as already current in a translation by 132 B.C. The date at which the various books were combined into a single work is not known, but the existence of the Septuagint as a whole may be assumed for the 1st century A.D., at which period the Greek version was universally accepted by the Jews of the Dispersion as Scripture, and from them passed on to the Christian Church.

In the 2nd century A.D. three new translations of the O.T. into Greek were made by Aquila, Symmachus and Theodotion. Aquila was a Jewish proselyte of Pontus whose version may be assigned to the first half of the 2nd century. It is characterized by extreme literalness, and clearly reflects the peculiar system of exegesis which was then in vogue among the Jewish rabbis. Its slavish adherence to the original caused the new translation to be received with favour by the Hellenistic Jews, among whom it quickly superseded the older Septuagint. For what remains of this version, which owing to its character is of the greatest value to the textual critic, we have until recently been indebted to Origen's *Hexapla* (see below). Fragments, however, of two codices were discovered (1897) in the *genizah* at Cairo, which illustrate more fully the peculiar features of this version.

The accounts given of Theodotion are somewhat conflicting. On the whole it is probable that Irenaeus has preserved the most trustworthy account, viz., that he was a Jewish proselyte whose translation preceded that of Aquila. Theodotion's version was not an independent translation, but rather a revision of the Septuagint on the basis of the current Hebrew text. He retained, however, those passages of which there was no Hebrew equivalent, and added translations of the Hebrew where the latter was not represented in the Septuagint. A peculiar feature of his translation is his excessive use of transliteration, but, apart from this, his work has many points of contact with the Septuagint, which it closely resembles in style; hence it is not surprising to find that later mss. of the Septuagint have been largely influenced by Theodotion's translation. In the case of the book of Daniel, the translation of Theodotion was definitely adopted by the Church, and is accordingly found in the place of the original Septuagint in all mss. and editions. It is interesting to note in this connection that renderings which agree in the most remarkable manner with Theodotion's version of Daniel are found not only in writers of

the 2nd century but also in the New Testament. The most probable explanation of this phenomenon is that these renderings are derived from an early Greek translation, differing from the Septuagint proper, but closely allied to that which Theodotion used as the basis of his revision.

Symmachus, according to Eusebius and Jerome, was an Ebionite. He is not mentioned by Irenaeus and his date is uncertain, but probably his work is to be assigned to the end of the 2nd century. His version was commended by Jerome as giving the sense of the original, and in that respect it forms a direct contrast with that of Aquila. Indeed Dr Swete thinks it probable that "he wrote with Aquila's version before him (and that) in his efforts to recast it he made free use both of the Septuagint and of Theodotion."

As in the case of Aquila, our knowledge of the works of Theodotion and Symmachus is practically limited to the fragments that have been preserved through the labours of Origen. This writer (*see* ORIGEN) conceived the idea of collecting all the existing Greek versions of the O.T. with a view to recovering the original text of the Septuagint, partly by their aid and partly by means of the current Hebrew text. He accordingly arranged the texts to be compared in six parallel columns in the following order: (1) the Hebrew text; (2) the Hebrew transliterated into Greek letters; (3) Aquila; (4) Symmachus; (5) the Septuagint; and (6) Theodotion. In the Septuagint column he drew attention to those passages for which there was no Hebrew equivalent by prefixing an obelus; but where the Septuagint had nothing corresponding to the Hebrew text he supplied the omission, chiefly but not entirely from the translation of Theodotion, placing an asterisk at the beginning of the interpolation; the close of the passage to which the obelus or the asterisk was prefixed was denoted by the metobelus. That Origen did not succeed in his object of recovering the original Septuagint is due to the fact that he started with the false conception that the original text of the Septuagint must be that which coincided most nearly with the current Hebrew text. Indeed, the result of his monumental labours has been to impede rather than to promote the restoration of the genuine Septuagint. For the Hexaplar text which he thus produced not only effaced many of the most characteristic features of the old version, but also exercised a prejudicial influence on the mss. of that version.

The *Hexapla* as a whole was far too large to be copied, but the revised Septuagint text was published separately by Eusebius and Pamphilus, and was extensively used in Palestine during the 4th century. During the same period two other recensions made their appearance, that of Hesychius which was current in Egypt, and that of Lucian which became the accepted text of the Antiochene Church. Of Hesychius little is known. Traces of his revision are to be found in the Egyptian mss., especially the *Codex Marchalianus*, and in the quotations of Cyril of Alexandria. Lucian was a priest of Antioch who was martyred at Nicomedia in A.D. 311 or 312. His revision (to quote Dr Swete) "was doubtless an attempt to revise the κοινή (or 'common text' of the Septuagint) in accordance with the principles of criticism which were accepted at Antioch." To Ceriani is due the discovery that the text preserved by codices 19, 82, 93, 108, really represents Lucian's recension; the same conclusion was reached independently by Lagarde, who combined codex 118 with the four mentioned above. As Field (*Hexapla*, p. 87) has shown, this discovery is confirmed by the marginal readings of the *Syro-Hexapla*. The recension is characterized by the substitution of synonyms for the words originally used by the Septuagint, and by the frequent occurrence of double renderings, but its chief claim to critical importance rests on the fact that "it embodies renderings not found in other mss. of the Septuagint which presuppose a Hebrew original self-evidently superior in the passages concerned to the existing Massoretic text." (Driver)

Latin Versions.—Of even greater importance in this respect is the Old Latin version, which undoubtedly represents a Greek original prior to the *Hexapla*. "The earliest form of the version" (to quote Dr Kennedy) "to which we can assign a definite date, viz., that used by Cyprian, plainly circulated in Africa." In the

view of many authorities this version was first produced at Carthage, but recent writers are inclined to regard Antioch as its birthplace, a view which is supported by the remarkable agreement of its readings with the Lucianic recension and with the early Syriac mss. Unfortunately the version is only extant in a fragmentary form, being preserved partly in mss., partly in quotations of the Fathers. The non-canonical books of the Vulgate, however, which do not appear to have been revised by Jerome, still represent the older version. It was not until after the 6th century that the Old Latin was finally superseded by the Vulgate or Latin translation of the O.T. made by Jerome during the last quarter of the 4th century. This new version was translated from the Hebrew, but Jerome also made use of the Greek versions, more especially of Symmachus. His original intention was to revise the Old Latin, and his two revisions of the Psalter, the Roman and the Gallican, the latter modelled on the *Hexapla*, still survive. Of the other books, which he revised according to the Hexaplar text, that of Job has alone come down to us. For textual purposes the Vulgate possesses but little value, since it presupposes a Hebrew original practically identical with the text stereotyped by the Massoretes.

Syriac Versions.—The Peshito (P'shitta) or "simple" revision of the O.T. is a translation from the Hebrew, though certain books appear to have been influenced by the Septuagint. Its date is unknown, but it is usually assigned to the 2nd century A.D. Its value for textual purposes is not great, partly because the underlying text is the same as the Massoretic, partly because the Syriac text has at different times been harmonized with that of the Septuagint.

The Syro-Hexaplar version, on the other hand, is extremely valuable for critical purposes. This Syriac translation of the Septuagint column of the *Hexapla* was made by Paul, bishop of Tella, at Alexandria in A.D. 616–617. Its value consists in the extreme literalness of the translation, which renders it possible to recover the Greek original with considerable certainty. It has further preserved the critical signs employed by Origen as well as many readings from the other Greek versions; hence it forms our chief authority for reconstructing the *Hexapla*. The greater part of this work is still extant; the poetical and prophetic books have been preserved in the *Codex Ambrosianus* at Milan (published in photo-lithography by Ceriani, *Mon. Sacr. et Prof.*), and the remaining portions of the other books have been collected by Lagarde in his *Bibliothecae Syriacae*, etc.

Of the remaining versions of the O.T. the most important are the Egyptian, Ethiopic, Arabic, Gothic and Armenian, all of which, except a part of the Arabic, appear to have been made through the medium of the Septuagint. (J. F. S.)

3. TEXTUAL CRITICISM

The aim of scientific Old Testament scholarship is to obtain a full appreciation of the Old Testament literature, of the life out of which it grew, and the secret of the influence which these have exerted and still exert. For this many things are needed, among which criticism is prominent. Of criticism there are several branches. First, the errors which have crept into the text must be detected and the text be restored as far as possible to its original form; this is the task of Textual or Lower Criticism. Exegesis must interpret the text thus recovered so as to bring out the meaning intended by the authors. The attempt must then be made to determine the scope, purpose and character of the various books, the times in and conditions under which they were written, whether they are severally the work of one or of more authors, at what date they reached their present form, whether they embody earlier sources, and, if so, to reconstruct these and assign dates to them. This is the province of Higher Criticism, so called to distinguish it from Lower Criticism. A further task is to estimate the value of this literature as evidence for the history of Israel; to determine, as far as possible, whether such parts of the literature as are contemporary with the time described present correct, or whether in any respect one-sided or biased or otherwise incorrect descriptions; and again, how far the literature that relates the story of long past periods has drawn upon trustworthy

records, and how far it is possible to extract historical truth from traditions (such as those of the Pentateuch) that present, owing to the gradual accretions and modifications of intervening generations, a composite picture of the period described, or from a work such as Chronicles, which is written on the assumption that the institutions and ideas of the present must have been established and current in the past. This is sometimes assigned to the province of Higher Criticism, but it is desirable to limit this term to the problems of authorship, date and literary analysis and to use the term "Historical Criticism" to cover the questions as to the historical value of the sources themselves and the historicity or otherwise of the narratives they tell. It must use all available and well-sifted evidence, whether derived from the Old Testament or elsewhere, to reconstruct the history of Israel. The supreme aim of the Old Testament student is to trace the growth and determine the character of the religion of Israel. Since revelation is a process in history, the history must be known that the revelation may be understood. For this all types of criticism are necessary; the lower that the text may as far as possible be exactly determined; the higher that the documentary sources may be ascertained and placed in their chronological order; the historical that the trustworthiness of the documents and the historicity of the stories they relate may be ascertained. In this section we are concerned with the textual or lower criticism. This, like all other branches of criticism, is very largely of modern growth.

At the basis of all sound study of the literature is the construction of a text as accurate as criticism can make it; and for a long time this first essential was lacking. Jewish study was exclusively based on the official Hebrew text, fixed probably in the 2nd century A.D. and thereafter scrupulously preserved. But it is obvious that this text already contained certain corruptions. This is clear from various considerations. Certain passages cannot be translated without violence as they stand. Passages occur more than once with variations, sometimes perhaps deliberate, but in other cases only to be reasonably accounted for on the theory that one of the variations is due to corruption. The translations of the Old Testament, notably the Septuagint, frequently present a different and in many instances undeniably a superior text. The official Hebrew text had probably suffered more corruption than can now, or perhaps ever will be, detected with certainty. While Jewish scholars who worked on the Hebrew text were placed at a disadvantage by its corruptions, Jewish Alexandrian and Christian scholars were more seriously hampered because they were dependent upon translations, especially the Septuagint. Although this earliest of the Greek versions was rendered from an earlier and purer form of the Hebrew text than that now preserved, those who were restricted to it were in a much worse position than those who could read Hebrew, partly because it was a translation, and partly because the translation was so defective. In his *Hexapla*, Origen placed in parallel columns the Hebrew, the Septuagint and certain later Greek versions, and thus brought together the chief existing evidence to the text. This, unhappily, is preserved only in fragments. Latin-speaking scholars were dependent on a Latin translation of the Greek translation, and thus studied the Old Testament at a double remove from the original. Jerome made a fresh Latin translation direct from the received Hebrew text. Though greatly opposed at first, this version (the Vulgate) subsequently became the basis of western Biblical scholarship. Thus the uncritical text of the original and the common use, not of the original, but of a version, reacted unfavourably on critical study. And this was aggravated by unsound methods of interpretation, legal or dogmatic or allegorical.

Critical method was not invented by biblical scholars and it was not applied to the Bible in order to discredit it. Biblical scholars adopted it from the students of other ancient literatures; the textual criticism of the classical literatures prepared the way for the textual criticism of the Old Testament; Bentley's *Phalaris* (1699) preceded any thorough or systematic application of higher criticism to any part of the Old Testament; Niebuhr's *History of Rome* (1811) preceded Ewald's *History of Israel* (1853-1859).

The fundamental principles of the textual criticism of the Old Testament are the same as those which apply to any other ancient

text, and need not be described here (*see* TEXTUAL CRITICISM). But there are conditions peculiar to the text of the Old Testament which must be briefly described. The earliest Hebrew mss. of the Old Testament are not earlier than the 9th century A.D., or nearly 1,000 years after the latest parts of the Old Testament were written. These mss. and the ordinary Hebrew Bibles contain the text of the Old Testament itself, consisting only of consonants accompanied by vowels and accents which constitute a later Jewish interpretation. The Hebrew alphabet, like that of the Moabites, Aramaeans and Phoenicians, contained no vowels. Vowel signs and accents were invented by Jewish scholars between the 5th and 9th centuries A.D. After a prolonged and bitter conflict it was recognized by the end of the 17th century, thanks especially to the French Protestant scholar, Louis Capell, and the English Protestant scholar, Brian Walton, that the vowels were a later addition to the text. Yet the influence of tradition lingered long after it had been proved to be false. Thus the R.V. is intended to translate the vocalized text; and legitimate translations of the consonantal text are frequently, though unjustifiably, described as emendations if they depart from the Jewish interpretation as expressed in the vowels. Even before the vowel signs were invented certain consonants which had come to be employed for vowel sounds had been inserted into the original text. The biblical authors themselves had occasionally employed them, but in most cases they were inserted by transcribers and editors. There was probably in most cases no clear division of the consonants into words. The first requisite for a critical treatment is, accordingly, to consider the consonants by themselves, to treat every vowel-consonant as possibly not original, and the existing divisions of the text into words as original only in those cases where they yield a sense better than any other possible division (or, at least, as good). This involves much ambiguity and demands increased skill, but anything short of it falls short also of strict critical method. The perception of this is even now none too general.

The text, like all ancient texts, has suffered from accidents of transmission, from the mistakes of copyists. This was demonstrated, in spite of opposition, by Capellus. To cure corruptions and establish a critical text many things were needed: a complete collation of existing mss. of the Jewish text and of the Samaritan text of the Pentateuch, the establishment of a critical text of the Septuagint, a careful study of several versions directed to determining when real variants are implied and what they are. Not a little has been accomplished but much remains to be done. The Hebrew mss. were collated by Kennicott and De Rossi at the close of the 18th century with sufficient thoroughness to justify the important conclusion that all existing mss. reproduce a single recension. The Samaritan mss. are still imperfectly collated; the same is true of the Syriac and other versions except the Septuagint. For the Septuagint much has been done. Holmes and Parsons prepared an edition with a magnificent critical apparatus (1798-1827); a rather smaller but more careful collation by Cambridge scholars is in process of publication. Neither edition constructs a critical text. Lagarde's contributions to right critical method have been conspicuous. While the value of the Septuagint has been recognized, it has been uncritically used and the correctness of its Hebrew original, while perhaps generally underestimated, has also been exaggerated.

What, then, is the position when we have used all our available resources? So far as we can detect the Hebrew text which underlies the Septuagint, we can recover a Hebrew text of the Pentateuch current about 280 B.C. and for most of the rest of the Old Testament current about 100 B.C. The text we can recover, from comparison with the Hebrew mss., differed but slightly from that officially established before the end of the 2nd century A.D. Comparing these two lines of evidence, we can reach a text current about 300 B.C. or later, but not errors which had already affected the common source of both. Accordingly, errors lurk even where no variants now exist, which can be corrected, if at all, only by conjectural emendation. The dangers of this method are well known and many such emendations have been ill advised; but frequently the textual critic who is at once competent and honest must either offer such emendations or indicate that such passages

are corrupt and the means of restoring them lacking. Conjectural emendation was practised on a modest scale by earlier critics but far more extensively by critics from the closing decades of the 19th century onwards. Frequently this has been in the interests of restoring the metre where the critic has rightly or wrongly detected the presence of a particular rhythm. Wellhausen and Cornill, Bickell and Duhm, Cheyne and Driver may be specially mentioned for their contributions to textual criticism. A valuable conspectus of results may be seen in Kittel's *Biblia Hebraica*. The Hebrew edition of P. Haupt's *Sacred Books of the Old Testament* presents a critical text of the books included in it with critical notes. (G. B. Gr.; A. S. P.)

4. HIGHER AND HISTORICAL CRITICISM

Down to the time of the Reformation doubt was scarcely raised, either among Jews or Christians, as to the traditional beliefs about the date and authorship of Old Testament books. Porphyry, the Neoplatonist philosopher, discerned that Daniel was not written in the Babylonian captivity but in the time of Antiochus Epiphanes four centuries later. The great Jewish scholar Ibn Ezra in a cryptic note on Deut. i. 1 collects several indications which point, as he seems to perceive, to the post-Mosaic origin of the Pentateuch. He also appears to question the authorship of Isa. xl.-lxvi. The reformers were concerned with the authority of ecclesiastical tradition in the interpretation and use of scripture, but not specially so in literary and historical criticism. Yet Luther exercised considerable freedom, especially as to the extent of the Canon, but also as to several questions of higher criticism. Thus for Luther it is a matter of indifference whether or not Moses wrote the Pentateuch; Chronicles he definitely pronounces less credible than Kings, and he considers that Isaiah, Jeremiah and Hosea probably owe their present form to later hands. Carlstadt definitely denied the Mosaic authorship of the Pentateuch, for Moses could not have related his own death; yet Deut. xxxiv. cannot be separated from the rest of the Pentateuch. The later scholastic Protestant doctrine of verbal infallibility necessarily encouraged critical reaction and proved a widely extended retarding force down into the 19th century. Nevertheless, criticism advanced by slow degrees among individuals, now in the Roman Church, now in the number of those who sat loosely to the restrictions of either Roman or Protestant authority, and now among Protestant scholars and theologians.

Thomas Hobbes in his *Leviathan* (1651) expressed a number of views on the Old Testament suggested to him by a critical study of it. The Pentateuch was written later than the time of Moses, but incorporated all that Moses is said to have written—for example, the law contained in Deut. xi.-xxvii., which is to be identified with the lost law discovered by Hilkiah and sent to Josiah. The historical books are considerably later than the history which they relate. The Psalter and Proverbs are in their present form late, though Ecclesiastes and the Song of Solomon are the work of Solomon. The whole Scripture assumed its present form after the return from Exile and before the time of Ptolemy Philadelphus. He insisted that, in default of external evidence, the critical problems must be solved by evidence drawn from the books themselves. Spinoza in his *Tractatus Theologico-politicus* (1671) drew attention in particular to the confused mixture of law and narrative in the Pentateuch, the occurrence of duplicate narratives and chronological incongruities. Father Simon in his *Histoire critique du Vieux Testament* (1682) also argues that the Pentateuch is the work of more than one author, and makes an important advance towards a systematic analysis by observing that the style varies, being sometimes very curt and sometimes very copious, "although the variety of the matter does not require it."

The first attempt at a continuous analysis was made by a French Roman Catholic physician, Jean Astruc. In a work published anonymously in 1753 under the title *Conjectures sur les mémoires originaux dont il paroît que Moïse s'est servi pour composer le livre de la Genèse*, he argued that in Genesis and Exod. i. 2 Moses had used different documents, and that of these

the two chief were distinguished by their use of different Divine names—Elohim and Yahweh; by the use of this clue he gave a detailed analysis of the passages belonging to several documents. His criteria were too slight to give to all the details of his analysis anything approaching finality; but his criteria, so far as they went, were valid, and his results, broadly speaking, sound though incomplete. In particular they have abundantly justified his really important fundamental theory that the documents used by the compiler have been incorporated so much as they lay before him that we can get behind them to the earlier sources and thus carry back the evidence beyond the date of compilation to the earlier date of the sources. In identifying the compiler with Moses he failed to profit from some of his predecessors; and his adhesion to the Mosaic origin of the Pentateuch presumably blinded him to the similar phenomena which justify an analysis of the remaining books.

The same year saw the publication of Lowth's *De Sacra poesi Hebraeorum*; he issued a translation of Isaiah with notes in 1778. Both were translated into German and exerted considerable influence in Germany. Lowth's contribution to a more critical appreciation of the Old Testament lies in his perception of the nature and significance of parallelism in Hebrew poetry, in his discernment of the extent to which the prophetic books are poetical form, and in his treatment of the Old Testament as the expression of the thought and emotions of a people—in a word as *literature*.

In spite of these earlier achievements it is J. G. Eichhorn who has, not without reason, been termed the founder of modern Old Testament criticism. The publication of his *Einleitung (Introduction to the Old Testament)* in 1780-83, is a landmark in the history of Old Testament criticism. A friend of Herder, and himself keenly interested in literature, he treats the Old Testament as literature—like Lowth, but more thoroughly; himself an Oriental scholar, he treats it as an Oriental literature. His work is the first comprehensive treatment of the entire Old Testament in this manner. While much of the voluminous detail is provisional, most of the broad conclusions of literary criticism which emerge have passed after more than a century of keen and sometimes hostile examination, into the number of historical certainties or high probabilities. On linguistic grounds he argues that Ecclesiastes is as late as the Persian period 538-332 B.C. and that the Song of Solomon does not belong to the Solomonian age. He argues that "in our Isaiah are many oracles not the work of this prophet." Parts of Daniel belong to the exile, other parts are later. Moses was the author of the Pentateuch, but Genesis is analysed on lines similar to Astruc's analysis. He distinguishes the priests' code of the middle books of the Pentateuch and Deuteronomy the people's law book; and admits that even the books which follow Genesis consist of different documents, many incomplete and fragmentary (hence the title "Fragment-hypothesis"), but all the work of Moses and some of his contemporaries.

In his incomplete critically annotated translation of the Old Testament A. Geddes (1792-1800), a Scottish Romanist priest, argued that the Pentateuch rests on a variety of sources, partly written, partly oral, but was compiled in Canaan probably in the reign of Solomon. He rejected the clue from the variation in the divine names used by Astruc and Eichhorn. K. D. Ilgen in 1798 anticipated later criticism by pointing out that in Genesis two documents employed the divine name Elohim and consequently criticism had to reckon with three main sources. The fragment-hypothesis was elaborated by J. S. Vater (1802-05). A new stage opens with De Wette's early and exceedingly influential work, *Die Beiträge zur Einleitung in das Alte Testament* (1806-07). He carried criticism beyond literary analysis and appreciation to the determination of the worth to be attached to the documents as records. He gave a detailed proof of the untrustworthiness of Chronicles and thus cleared the way for that truer view of the history and religion of Israel which the treatment of Chronicles as trustworthy hopelessly obscured. His most influential and enduring contributions to Pentateuchal criticism were his proof that Deuteronomy belongs to the 7th century B.C. and his insistence that the theory of the Mosaic origin of all the institutions

described in the Pentateuch is incompatible with the history recorded in Judges, Samuel and Kings.

Strong in historical criticism, De Wette was weak in historical construction. But what he failed to give, Ewald supplied; and if more of De Wette's than Ewald's work still stands to-day, this is but an illustration of the melancholy fact that in history negative criticism is surer than positive construction. Ewald's *History of the People of Israel* (1843-59) was the first attempt on the grand scale to synthesize the results of criticism and present Israel's history as a great reality of the past. By the force of his wide learning, and even more of his personality, he long exercised an all-pervading and almost irresistible influence; and Stanley's *Lectures on the History of the Jewish Church* (1863-76) is among the fruits. He closes one epoch of Old Testament criticism: by his influence he retards the development of the next.

The criticism of the Pentateuch is concerned first with the discovery of the documentary sources and their delimitation, secondly with their arrangement in chronological order and their dates. It must be remembered that it was not till 1853 that Hupfeld in his *Sources of Genesis* demonstrated, what Ilgen had half a century earlier affirmed, that two documents used Elohim as a proper name. The modern documentary analysis was thus established which recognized four documents: the Yahwist (J), the two Elohist documents (P and E) and Deuteronomy (D). It was generally held that P was the earliest and D was the latest. But the Grafian theory put forward in 1865 by K. H. Graf, though at the outset with an indefensible partition of P into early narrative and late legal material, assumed under Kuenen's influence its true form and affirmed that P as a whole was later than Deuteronomy and Ezekiel. In this, however, Graf had been largely anticipated by his teacher E. Reuss in his lecture room (1833-34), and by two Hegelian scholars, Vatke and George. In its final form it asserted that the order of the documents was JE, D, P, the legislation in Ezek. xl-xlviii. forming the transition from D to P. Vatke had the merit of first bringing out the essential character of the movement. Its fundamental peculiarity lies in the fact that it is a criticism of what is supreme in Israel—its religion—and that it has rendered possible a true appreciation of this by showing that, like all living and life-giving systems of thought, belief and practice, the religion of Israel was subject to development. It seized on the prophetic element, and not the ceremonial, as containing what is essential and unique in the religion of Israel.

It was in the field of religious institutions, however, that the demonstration of the Grafian arrangement of the documents was most decisively given. The older view that P, with its exact details and developed ceremonial and sacerdotal system, was at once the earliest portion of the Pentateuch and the Grundschrift or foundation of the whole was maintained by Ewald and his school. The delay in the triumph of the Grafian criticism was due partly to the hostility of Ewald and his school, but in large part to the development of his theory by Vatke on *a priori* grounds in accordance with the principles of Hegel's philosophy of history. It was only after a fresh and keener observation of facts that the new theory made rapid progress. Graf was a pupil of Reuss. The master's divination that the true order was not Law, Psalms, Prophets, but Prophets, Law, Psalms, was reasoned out by his pupil. The famous Dutch scholar Kuenen accepted Graf's demonstration in a revised form, made it the basis of his masterly *Religion of Israel* (1869-70) and supported it by a long series of brilliant essays in the *Theologisch Tijdschrift*. Colenso, though he never entirely accepted the theory, contributed by his searching analysis of the unreality of P's narrative to the formation, or ratification, of the judgment on that document which is fundamental to it. It was J. Wellhausen who decisively changed the current of critical opinion by his *Geschichte Israels*, vol. i. (1878), known in its subsequent editions as *Prolegomena zur Geschichte Israels*. It was translated into English in 1885, with a preface by W. Robertson Smith (*q.v.*), who, with S. R. Driver (*q.v.*), was among the leading exponents of the new standpoint in the English-speaking world.

The Grafian theory found adherents in Holland and Great

Britain, but only hostility in Germany till, in 1875, B. Duhm in his *Theologie der Propheten* "broke the consensus of German critics" (Kuenen). Wellhausen's history of Israel was, once more to quote Kuenen, "the crowning fight in the long campaign." From that time the theory became so widely accepted, though some very eminent scholars held out against it, that it remained for many years the orthodox critical view. Recently, however, from various sides the position has been attacked. Those who stand for the traditional view have argued that the distinction in the use of the divine names cannot be relied upon in the documentary analysis because the Hebrew text is in this respect frequently shown to be an insecure basis, owing to the variations in the Septuagint. This has been urged not simply by defenders of tradition such as Dahse and Wiener, but also by Eerdmans, who has formulated a new critical theory. But this has not had the far-reaching results anticipated by its advocates. The distinction in the divine names was actually the starting point for the analysis. It is not the foundation on which it rests, and it is only one clue to analysis among a number. It is in fact easier for critics to separate P from E where the divine names are identical than to separate E from J in which they are distinct. Moreover the investigation of the textual transmission of the divine names, especially by J. Skinner, *The Divine Names in Genesis* (1914), has resulted in the vindication of the general correctness of the Hebrew where the Greek differs from it. But some of those who accept the documentary analysis have shown a tendency to move from the Grafian position, sometimes in a more conservative, sometimes in a more radical direction. This has in both instances been connected with an attack on the generally accepted date of Deuteronomy. This has been the pivot on which the criticism of the Pentateuch has largely turned. It was the unquestioned belief of Grafians and pre-Grafians alike that the Law Book of Josiah's Reformation was to be identified with some form of Deuteronomy. Deuteronomy was supposed by the pre-Grafians to represent the final stage of legislation, but by the Grafians to initiate with the centralization of the worship, a process which had its sequel in Ezekiel and culminated in the priestly code. It has recently been argued that Deuteronomy was really very much earlier than the 7th century. A. C. Welch has put forward the view that, apart from the opening section of the legislation in Deut. xii-xxvi., the detailed regulations contemplate a plurality of high places. The current view has been occasioned simply by the opening law which demands centralization. This he takes to be a late prefix against which Jeremiah protested in the words, "the false pen of the scribes hath wrought falsely" (Jer. viii. 8). On the other hand a late date of Deuteronomy has been urged by R. H. Kennett (since 1905-06), and more recently G. Holscher has argued that Deuteronomy was really written about 500 B.C. He recognizes the correctness of the view that the Book of Ezekiel is post-Deuteronomical and, since the prophet himself flourished in the first quarter of the 6th century, he regards the larger part of the book as not written by him. It is accordingly not surprising that the priestly legislation is relegated by Holscher to a later date than that commonly assigned to it and that the whole story of Ezra and his reformation is treated as suspicious. It is scarcely likely that a reconstruction which involves so drastic and negative a criticism will prove acceptable. But the significant thing is that Holscher adheres to the *Grafian sequence* of documents—Deuteronomy, Ezekiel, P.

On the detailed criticism of the other books reference must be made to the special articles devoted to them. But some general observations are necessary here. At a quite early date in the history of modern criticism it was recognized that Isaiah xl-lxvi. and several sections in the earlier part of the book, could not be the work of Isaiah himself. Similarly Zech. ix-xiv., it was seen, could not have been written by Zechariah, the contemporary of Haggai. Doubt was felt as to the authorship of Micah vi. vii. but till the closing decades of the 19th century the criticism of the prophets was on the whole conservative. This is excellently illustrated by the commentary on *Jeremiah* (1862) issued by so advanced a critic as Graf. In 1892 Wellhausen's *Minor Prophets* and Duhm's *Isaiah* fully initiated the more advanced criticism

of the prophets. The range of non-authentic prophecies was enlarged and the text more freely handled, interpolations in authentic prophecies were recognized on a larger scale and the addition of happy endings. Duhm brought down not a little in Isa. i.-xxxv. into the Maccabean period. Marti followed up his criticism in a more thorough-going fashion. Duhm's handling of Jeremiah and the minor prophets gave a further illustration of his general principles. In particular the belief that eschatology was a late development created, as Wellhausen argued, by the literary study of the earlier prophets, resulted in the belief that nearly all the predictions of a happy future should be relegated to a period later than Ezekiel, with whom the movement had begun. The more recent development has been characterized by a reaction with which the names of Sellin in one way, Gunkel and Gressmann in another, have been associated. This has not been limited to the criticism of the prophets, it has affected most of the Old Testament books. It has been specially due to the feeling that the history, literature and religion of Israel must be placed far more fully in their international context. Israel was a very young people; great civilizations and cultures had been developed, millenniums before its birth, especially in Babylonia and Egypt. To these Israel owed a great debt. The earliest legislation of the Hebrews drew on much more ancient law and custom. The stories of the Creation and the Deluge go back to myths and legends of a far older time. The eschatological scheme found in the prophets is asserted to be of foreign origin. The Hebrews themselves were in contact with various civilizations outside of Palestine, while in Palestine itself layer after layer of foreign culture had been deposited. The general result has been to reverse the radical direction of criticism. Not that there is any widespread tendency to rehabilitate the traditional view of the Pentateuch; the Grafian theory is probably that still generally accepted. But in the case of the Psalms not only would such extravagances as Duhm's view that the bulk of the Psalter belongs to the 2nd and 1st centuries B.C. be generally rejected; but there would be much greater willingness to admit a substantial pre-exilic element in the Psalter. It must, of course, be recognized that all pre-exilic prophecy has come down to us in the works of post-exilic editors, so that the problem is not what elements in the books are later than the prophets whose name they bear, but, from these post-exilic collections, how are the pre-exilic elements to be extracted?

(G. B. Gr.; A. S. P.)

BIBLIOGRAPHY.—Only a few works on the Old Testament can be mentioned. S. R. Driver's *Introduction to the Literature of the Old Testament* (1891, 9th ed. 1913) is the standard work, and like all his writings (see especially his *Genesis in the Westminster series*), cautious, exact and judicial. Steuernagel, *Einleitung in das Alte Testament* (1912), is the most comprehensive recent German work; Cornill, *Introduction to the Canonical Books of the Old Testament* (1907), represents a more radical, Sellin, *Introduction to the Old Testament* (1922), a more conservative movement in the critical camp. The points at issue are discussed in Cornill, *Zur Einleitung in das Alte Testament* (1912), and Sellin's reply published under the same title and in the same year; see also J. E. McFadyen, "The Present Position of Old Testament Criticism" in *The People and the Book* (ed. Peake). For the most recent developments see Meinhold's useful *Einführung in das Alte Testament* (2nd ed. 1926), G. Hölscher, *Geschichte der Israelitischen und Jüdischen Religion* (1922), radical, and indeed revolutionary. W. Robertson Smith's *The Old Testament in the Jewish Church* (2nd ed. 1892) is perhaps still the best fitted to initiate the student into the subject; J. Orr, *The Problem of the Old Testament* (1905), the best conservative statement. On special parts of the field: Kuenen, *The Hexateuch* (1886) and Wellhausen, *Prolegomena to the History of Israel* (1885), are great classics. Valuable also are J. E. Carpenter, *The Composition of the Hexateuch* (1902); Cheyne, *Job and Solomon* (1887), *The Origin and Religious Contents of the Psalter* (1891), and *Introduction to the Book of Isaiah* (1894). On the history of Criticism, see Cheyne, *The Founders of Old Testament Criticism* (1893); J. E. Carpenter, *The Bible in the 19th Century* (1903). Recent bibliographies are provided in *A Commentary on the Bible* (1919), and *The People and the Book* (1925), both edited by A. S. Peake; Sellin's *Introduction to the Old Testament* (1923); *The Cambridge Ancient History*, vol. iii. (1925), pp. 729-740, vol. vi. (1927), pp. 578-579; N. Baynes, *Israel among the Nations* (1927); *A Scripture Bibliography* (with annotations); A. Dufourcq, *Les Religions Païennes et la Rel. Juive* (Paris, 6th ed., 1923), and see HEBREW RELIGION; JEWS; PALESTINE and other relevant special articles. (A. S. P.)

3. CHRONOLOGY

The importance of a fixed standard of chronology was only gradually felt in the history of the world. When the feeling arose, events were probably at first dated by the regnal years of kings; the reigns of successive kings were then arranged in order and grouped, if necessary, in dynasties, whereby a standard by degrees was constructed. Particular states frequently introduced fixed eras, which obtained a certain currency, as that of the Seleucidae at Antioch (312 B.C.), which the Jewish author of I. Maccabees follows. Some of the oldest documents, like the early Babylonian contract-tablets, are dated by the year in which some noticeable event occurred; examples of this method are found even in the Old Testament (e.g., in Isa. vi. 1; xx. 1; Amos i. 1). During and after the exile, however, dating by the regnal year of the king became general, after the later Babylonian custom (e.g., Isa. xxxvi. 1). The Babylonians and Assyrians were probably the first to employ fixed chronological standards; and numerous contract-tablets and lists of kings and yearly officials attest their precision in noting chronological details. Biblical chronology is in many respects uncertain. Before the monarchy conditions for securing an exact and consecutive chronology did not exist; the dates in the earlier history, though apparently often precise, were in fact added long after the events described and often rested upon an artificial basis, so that the precision is in reality illusory. Even after its establishment, although the required conditions existed, errors by various means crept into the figures, so that the dates as recorded frequently err by two to three decades of years. The exact dates of biblical events can be determined only when the figures in the Old Testament can be checked or corrected by the contemporary monuments of Assyria and Babylonia, or by the independent chronology of the Persian and Seleucid kings.

I. In the period from the creation of man to the Exodus the chronology, in so far as it consists of definite figures, depends upon the so-called "Priestly Narrative" of the Pentateuch. The figures are mostly, if not always, artificial, although the means now fail of determining upon what principles they were calculated. It is also noteworthy that in the Samaritan text as in the Greek version of the Pentateuch the figures, especially from the Creation to the birth of Abraham, differ considerably from those of the Hebrew text, yielding in the Samaritan a lower, but in the Greek a much higher, total (*cf.* Skinner, *Genesis*, pp. 234-235).

To the period from the Creation to the Flood the Hebrew text assigns 1656 (Samaritan, 1307; Greek, 2262) years. The names obviously belong to the prehistoric age and equally with the figures are as destitute of historical value as those of Babylonian mythology (S. R. Driver, *Genesis*, pp. 79-80 and 432).

To the period from the Flood to the call of Abraham, the Hebrew writer allows 365 (Samaritan, 1015; Greek, 1145) years. The ages of the patriarchs show that these figures are mythical; yet the age of each at the birth of the next might in itself be historical (S. R. Driver, *op. cit.*, pp. 137-138). The figures conceivably go back, through Berossus, to a Babylonian source; but they possess no historical value: accepting even Ussher's date of the Exodus, 1491 B.C., which is earlier than is probable, we should thereby obtain for the creation of man 4157 (Greek, 5328) B.C. and for the confusion of tongues 2501 (Greek, 3066) B.C. But Egyptian and Babylonian monuments prove that man appeared upon the earth long before either date for the Creation; and numerous Egyptian, Sumerian and Babylonian inscriptions of an age considerably earlier than either date of the confusion of tongues are preserved. The figures of Gen. v. and xi. merely indicate the manner in which the priestly writer—and probably to some extent tradition—pictured the course of these early ages. The lives of the patriarchs (except Enoch) in Gen. v. are much longer than those of the patriarchs in Gen. xi., and similarly the ages in Gen. xi. 10-18 are higher than those in Gen. xi. 19-26; it is thus a collateral aim of the author to exemplify a supposed gradual diminution in the length of life.

The patriarchs' sojourn in Canaan, from the call of Abraham to the Exodus, is reckoned at 215 years and the Israelites' sojourn in Egypt at 430 years. Thus from the Creation to the Exodus the total is 2,666 years. Now the 4th year of Solomon is equated with

the 480th year from the Exodus (I. Kings vi. 1); Ussher, therefore, dating Solomon's reign 1014-975 B.C.—at least 50 years too soon—placed the Exodus in 1491 B.C., the call of Abraham in 2501 B.C. and the Creation in 4004 (which should rather be 4157) B.C. (S. R. Driver, *op. cit.*, pp. xxvii.-xxviii.).

These figures raise suspicions; for the fact that 2,666 is just two-thirds of 4,000 has suggested the inference that it was reached by artificial computation. Further, the various documents composing the early narratives are mutually inconsistent. For example, the plain intention of Exod. xii. 40-41 is to describe the Israelites as having dwelt in Egypt for 430 years, which substantially agrees with Gen. xv. 13. It does not, however, accord with other passages, which assign only four generations from Jacob's children to Moses (Exod. vi. 16-20; Num. xvi. 5-9; cf. Gen. xv. 16), or five to Joshua (Josh. vii. 1); and therefore, no doubt, the Samaritan and Greek read in Exod. xii. 40 that "the sojourning of the children of Israel in the land of Egypt, and in the land of Canaan, was 430 years," reducing the period in Egypt to half of that stated in the Hebrew text; viz., 215 years. This computation attained currency among the later Jews, e.g., Josephus amongst others (cf. St. Paul's "400 years" in Gal. iii. 17); and the unnatural rendering of Exod. xii. 40 in the A.V. (as contrasted with R.V.), which Ussher followed, was intended to make it possible. The facts here briefly noted make it clear how precarious and in parts impossible the chronology of this period is.

Can any of these dates be fixed by external evidence? Several attempts, based on Gen. xiv. have been made to date Abraham. Thus Amraphel, "king of Shinar," has been identified with Khammurabi, 6th king (c. 2067-2025 B.C.) of the 1st Babylonian dynasty, although the equation of Shinar with Babylonia is doubtful (*ibid.*, p. 445), and Tidal, "king of Goiim," has been identified with several Hittite kings, preferably with Tudkhialia I. (c. 1650 B.C.), who founded the Hittite empire (*ibid.*, pp. 448-450). All that can be said is that the second is perhaps more probable than the first suggestion, if one is held to exclude the other; for to accept both identifications requires the assumption that 400 years of history have been "telescoped" into one generation. It is best to admit the truth, that our knowledge is still too uncertain to settle the question. The date of the Exodus is almost equally doubtful; for example, it has been associated with the Hyksos dynasty (c. 1800-1600 B.C.) with Amenhotep III. and IV. (c. 1411-1360 B.C.) with Rameses II. and Merneptah (c. 1292-1198 B.C.) and even with the 20th dynasty (c. 1205-1100 B.C.). In spite of the shortening of the period between it and the founding of the kingdom, the age of Merneptah seems best to satisfy the conditions (S. R. Driver, *Exodus*, pp. viii. and xxx.-xlii.; see *Exodus*).

II. The period from the Exodus to the foundation of the Temple in the 4th year of Solomon is reckoned at 480 (Greek, 440) years (I. Kings vi. 1); but, if the number of years given for the various events by the Hebrew writers is added, the total is 534, or with the addition of the uncertain 20 years of Samuel's judgeship (I. Sam. vii. 2 and 15) 554 years; to this must be added the unknown number of years under Joshua and the elders (Judges ii. 7) and Saul (I. Sam. xiii. 1).

This period might be reduced to 480 years by the supposition, in itself not improbable, that some of the judges were local and contemporaneous; it has also been suggested that, after the Oriental fashion, the years of foreign domination were omitted, each judge's rule being reckoned not from the victory which brought him into power but from the death of his predecessor; we should thus obtain for this period $440 + x + y$ years—viz., 40 in the wilderness; x for Joshua and the elders; 40 for Othniel; 80 for Ehud; 40 each for Barak and Gideon; 76 for Jephthah and the 5 minor judges; 40 for Eli; 20(?) for Samuel; y for Saul; 40 for David, and 4 of Solomon's reign—which, if 30 years be assigned conjecturally to Joshua and the elders and 10 years to Saul, would amount to 480 years. The terms used, however—viz., "the land had rest forty years" in Judges iii. 11; and similarly in iii. 30; v. 61, and viii. 28—hardly admit of the latter supposition; and, if they did, the correctness of the 480 years could scarcely be maintained. It is difficult to harmonize with the most probable date of the Exodus; it is, moreover, open to the suspicion of having been

formed artificially, upon the assumption that the period in question consisted of 12 generations of 40 years each. In the years assigned to the judges, also, the frequency of the number 40 (which was seemingly regarded as a round number) is suspicious. On the whole no certain chronology of this period is yet attainable (cf. Burney, *Judges*, pp. 1-54).

III. From the foundation of the Temple to the captivity of Judah the dates are more abundant and more nearly correct than in any earlier period; nevertheless in details there is much uncertainty and difficulty. The Books of Kings were compiled about the beginning of the exile, and one object of the compiler was to give a consecutive and complete chronology of the period embraced by it. He therefore both noted carefully the length of each king's reign in both kingdoms, and (as long as the northern kingdom existed) correlated the history of the two by equating the commencement of each reign in the one with the year of the reign of the contemporary king in the other kingdom.

In these notices the lengths of the reigns were derived, it may be supposed, either from tradition or from official annals—the "book of the chronicles of Israel" or "Judah"; but the "synchronisms"—i.e., the corresponding dates in the contemporary reigns in the other kingdom—were derived, it is practically certain, by computation from the lengths of the successive reigns. In some cases, perhaps, in the lengths of the reigns themselves, in other cases in the computations based upon them, errors which have vitiated more or less the entire chronology have crept in. The existence of these errors can be doubly demonstrated: (i.) the chronology of the two kingdoms is not consistent with itself; (ii.) the dates of various events as calculated by Ussher seriously disagree with the dates as fixed by contemporary Assyrian monuments which mention them.

(1) After the schism the first year of Jeroboam in Israel must coincide with the first year of Rehoboam in Judah; and after the death of Jehoram of Israel and Ahaziah of Judah in battle with Jehu the first year of Jehu in Israel must coincide with the first year of Athaliah in Judah: there are thus two fixed synchronisms. Now the regnal years of the kings of Israel from Jeroboam to Jehoram, when added together, amount to 98, while those of the kings of Judah from Rehoboam to Ahaziah, when added together, amount only to 95. This discrepancy alone would not be serious. But, when the regnal years in the two kingdoms from the division after Solomon's death to the fall of Samaria in the sixth year of Hezekiah are added, the total in the southern kingdom is 260 years, and in the northern kingdom only 241 years 7 months. This is a formidable discrepancy. Again, the length of the reigns of the various kings is not the same according to the traditional and the synchronistic figures. Since, however, it is clear on various grounds that these synchronisms are not original, any attempt to base a chronological scheme on them may be disregarded.

(2) The Assyrian method of chronological computation was particularly exact. A special officer was annually appointed who held office for and gave his name to the year; and lists of these eponymous officers have been discovered, running from 911 to 659 B.C. The accuracy of these "eponym canons" can frequently be checked by the royal annals. Thus throughout this period Assyrian chronology is certain; and the dates so established can be reduced to those of the modern calendar by calculations based on the record of an eclipse of the sun on June 15, 763 B.C. (G. Smith, *The Assyrian Eponym Canon*, pp. 29-41 and 82-83). By these means certain events in Hebrew history to which the Assyrian annals allude can be fixed. Such contacts are established in the reigns of Ahab (Rogers, *Cuneiform Parallels to the Old Testament*, pp. 294-297), Jehu (*ibid.*, pp. 303-304), Menahem (*ibid.*, pp. 313-316), Ahaz (*ibid.*, p. 322), Pekah and Hoshea (*ibid.*, pp. 320-321), Hezekiah (*ibid.*, pp. 341-345) and Manasseh (*ibid.*, pp. 355-357; cf. Schrader, *Keilinschriftliche Bibliothek*, vol. ii., pp. 160-161 and 238-241). There are similar references to the captures of Damascus (Rogers, *op. cit.*, pp. 317-320), Samaria (*ibid.*, pp. 326 and 331-332), and Ashdod (*ibid.*, pp. 328-331). The Babylonian chronology, though resting on a different principle, is equally accurate. Events in Babylonia were reckoned by the regnal years of each king; these can be dated with certainty from

animals separate these events by more than 20 years. If, therefore, his first year is put in 728 B.C., the length of Ahaz's reign must be reduced; if it is placed in 715 B.C. the reigns of the following kings must be shortened. These are the most important, but not all, the discrepancies in the chronology of the kings, especially in the 8th century B.C., but they prove that, unless Assyrian or Babylonian records touch those of Israel and Judah, no certainty is possible; nor, in spite of the ingenuity expended on the problem, have scholars reached any agreement. The presence of errors in the Biblical figures is patent, but it is not equally clear where the errors lie nor how the available years ought to be redistributed. Working backwards, however, from the few fixed points available, we may safely put the rise of the monarchy under Saul about 1025 B.C., the division of the kingdom about 937 or 933 B.C., and the beginning of the reigns of Omri and Ahab about 887 and 876 B.C. respectively. So unsatisfactory, however, is the evidence and so diverse the results obtained by scholars, that the remaining dates are left to be approximately calculated from the information already given.

Events in Jewish History

538	Edict of Cyrus II. (546-529 B.C.) permitting Jews to return to Palestine; return of many with Zerubbabel.
516-515	Completion of second Temple in sixth year of Darius I. (522-485 B.C.).

The Gospell off
the Sancte John.
The first Chapter.

In the beginning
was the word: and
the word was with
God, and the word
was God. The same
was in the beginning
with God. All things
came to be by him,
and without him
nothing came to be.
In him was life,
and the life was
the light of men.
The light shined
in darkness, and
the darkness
comprehended
it not. The same
came in the world,
and the world
knew him not.
He came to his
own, and his
own received
him not. But as
many as received
him, to them gave
he power to become
the sons of God,
which were born
not of blood, nor
of the will of men,
but of God.
That which was
made flesh, and
dwelt among us,
and we saw his
glory, as the
glory of the only
begotten son of
the father.

The Gospell of S. Matthew. 90. i.
The first Chapter.

Jesus is the son
of the generation off
David, the son of
the house of David,
the son of the
house of David.
Jesus began to
teach, and he
said, Blessed be
thou, O Israel:
for thou hast
said, Blessed be
he that putteth
his trust in the
Lord. For thou
hast said, Blessed
be the man that
will not see, nor
feel, nor touch,
nor taste, nor
smell, nor hear,
nor think, nor
understand, nor
know, nor feel,
nor taste, nor
smell, nor hear,
nor think, nor
understand, nor
know.

<i>Events in Jewish History—continued</i>	
458 B.C.	Return of exiles with Ezra in seventh year of Artaxerxes I. (464-425 B.C.).
445	Nehemiah's first visit to Jerusalem.
432	Nehemiah's second visit to Jerusalem.
c. 350	Deportation of many Jews to Hyrcania and Babylonia, probably for revolt against Persians.

V. The Persian empire fell before Alexander the Great in 333 B.C.; thenceforth the chronology securely depends at first on the Persian and afterwards on the Seleucid era. Among the principal events from the submission of the Jews to Alexander until the capture of Jerusalem by Pompey mention may be made of the following:

332	Submission of Jews to Alexander the Great.
320	Palestine conquered by Ptolemy I. Lagus, king of Egypt (322-285 B.C.).
198	Palestine wrested from Ptolemy V. Epiphanes, king of Egypt (205-182 B.C.), by Antiochus the Great, king of Syria (223-187 B.C.).
168	Attempt of Antiochus Epiphanes, king of Syria (175-164 B.C.), to suppress Jewish religion; suspension of public worship in Temple for three years.
167	Rise of Maccabees.
166-165	Victories of Judas Maccabaeus over generals of Antiochus.
165	Re-dedication of Temple.
160	Death of Judas Maccabaeus.
160-142	Jonathan, younger brother of Judas.
142-135	Simon, elder brother of Judas.
135-105	John Hyrcanus, son of Simon.
105-104	Aristobulus I., son of Hyrcanus.
104-78	Alexander Jannaeus, brother of Aristobulus I.
78-69	Salome (Alexandra), widow of Alexander Jannaeus.
69	Aristobulus II., son of Alexandra.
63	Capture of Jerusalem by Pompey and incorporation of Palestine in Roman province of Syria.

In these last two periods, although there are events in Biblical history which are not fully or unambiguously dated, there is otherwise no difficulty through the help of the "Ptolemaic Canon" and the fullness of the records of the surrounding nations.

(S. R. D.; G. R. D.)

NEW TESTAMENT

1. CANON

The expansion of the Christian Church in Europe during the 1st century stands for us as the beginning of a new era in history. But the movement wore a different aspect to those who shared in it: to them it was an end rather than a beginning. "The ends of the ages" had come upon them, and the consummation, they believed, could not be long delayed. The literature of the apostolic age, written as it was for the most part under this conviction, was not intended by its writers to be the permanent authority of a Church which was to remain for ages "militant here upon earth." It was called forth by the needs of a generation which expected to survive to see the end of history and the inauguration of God's kingdom. Thus the New Testament, as a collection of Scriptures, was an undesigned and unforeseen product of the apostolic age. The fervour of the first age cooled, as the fulfilment of its early hope was deferred, but it left a large and widespread body of believers who still continued, though in a changed world and with a changed emphasis, to cherish the faith and the ideals which they had learned from their first evangelists. The formation of the New Testament shows us how the Christian Society protected itself from dissolution by appeal to a recognized collection of apostolic writings.

We are not here concerned to trace the original circumstances which called forth the various books included in the New Testament. Information on this subject will be found under the headings of the various books. Our present concern is to show—as far as can be shown—how these books came to be collected and finally to be compacted into a single corpus of Christian Scripture—a New Testament, which took its place beside the Scriptures of the Old Testament inherited from the Jewish Church. Our enquiries will show us that by the end of the 2nd century the New Testament was already complete in idea, though it was not till the 4th century that the exact limits of the Canon were

finally and firmly drawn. But first we must turn to the Apostolic Church itself.

The Christians of the first age had, as we have seen, no idea of adding to Scripture. Many of them were Jews, and all of them, like the Jews, recognized the authority of the Old Testament: they differed from unconverted Jews—and sometimes also between themselves—only as to its interpretation and application. The Lord was the Messiah whom the prophets had foretold, and Christians found in the Old Testament the justification for their faith. But in addition to the Old Testament the Church had authorities of its own which from very early days existed in written form. These provided the materials for the New Testament of the 2nd century.

(1) *Sayings of Jesus Christ*.—A natural authority attached itself to the sayings and instructions of Jesus. Collections of sayings of Jesus, which in part or in whole have been embodied in the later "biographical" form of Gospel, must date back to very early times. Paul quotes a "word of the Lord" as indisputably authoritative (I. Thess. iv. 15; I. Cor. vii. 10; x. 14).

(2) *Apostolic Letters*.—Authority attached to the Twelve and also to other Apostles. God has set the Apostles first in the Church (1 Cor. xii. 28). By word when present, and by epistle when absent, Paul claimed—though not without opposition—to direct the Churches he had founded. His Epistles were intended to be read in public to the assembled congregation, and in some cases at any rate were preserved and treasured by the Churches to which they were addressed.

(3) *Prophecies*.—Perhaps the nearest approach to a Christian Scripture in the apostolic age was the prophecy, one example of which was finally embodied in the Canon. The author of the Apocalypse claims direct inspiration for his work, and he pronounces a curse on any who shall diminish or add to the words he has written (ch. xxii. 18).

(4) *Church Order*.—Lastly we may note a work which claims to give the teaching of the Lord through the 12 Apostles, the *Didache*. This work contains a summary guide to Christian morals and instructions with regard to the chief institutions of the Church. Its exact date and its exact place of origin are uncertain, but it appears to date from the later years of the 1st century when the leadership of the Church was passing from the enthusiastic missionaries of the first age to the local ministers, and was probably composed either in Syria or Palestine. The *Didache* is the forerunner of the later Church Orders—a class of writing which is not represented in the Canon of Scripture.

In the writings of the sub-apostolic age there is a marked decline in spiritual power, of which the authors themselves were not unconscious. Thus Ignatius of Antioch, though he can claim "to speak with God's own voice, give ye heed to the bishops and the presbyters and deacons" (Philadelph. vii. 1), yet clearly feels himself to hold a lower position than his apostolic predecessors: "I do not enjoin you, as Peter and Paul did. They were Apostles, I am a convict; they were free, but I am a slave to this very hour" (Rom. iv. 3). In these circumstances it was natural that the Church should cling jealously to the Gospels and to the apostolic writings which it had inherited, and this tendency was strengthened by the increasing pressure of heretical movements.

We have no certain knowledge as to how or where the fourfold Gospel Canon came to be formed. It is to be noted that Clement of Rome (c. A.D. 97) and Polycarp (c. 112) both quote sayings of the Lord in a form which is independent of any of the Gospels which afterwards became canonical. It is probable that each of the four canonical Gospels gained currency and prestige through being adopted by some one of the great Churches. Thus there is strong reason for associating Mark with Rome, whence it probably obtained currency in other Churches. Matthew—a revised and expanded Mark—appears to have been in use at Antioch at the beginning of the 2nd century. John is connected with Ephesus. Some think that the fourfold Gospel originated in Asia Minor, where we have evidence of comparative study of the merits of some of the Gospels early in the 2nd century. Others think it more likely that the fourfold Gospel came from Rome. In any case it probably represents concerted action to

standardize the Gospel which had been committed to the Church. Perhaps the apocryphal Gospel of Peter (not later than 140 and perhaps considerably earlier) provides our earliest testimony for the currency of the fourfold Gospel, for the writer appears to depend upon all of the four. Somewhat later (c. 170) Tatian at Rome undertakes in his Diatessaron to combine the four into a single harmony, while to Irenaeus (c. 185) it was as natural that there should be four Gospels as that there should be four winds and four quarters of the earth (*adv. Haeres.* iii. 11, 8). We may conclude that the fourfold Gospel had then been long established.

A collection of Pauline Epistles, including the Pastoral Epistles, dates from the beginning of the 2nd century at latest. Ignatius (c. 112) shows acquaintance with six Pauline Epistles, including I Tim and Tit., while the Epistle of Polycarp shortly afterwards refers to nine Epistles including I. and II. Timothy. The Pauline Epistles were also held in high estimation by the gnostic heresiarchs. Marcion (c. 140) acknowledged a collection of ten Pauline Epistles which did not include the Pastoral Epistles. It is perhaps more probable that this represented an earlier Pauline Corpus, than that Marcion deliberately rejected the Pastoral Epistles.

By the middle of the 2nd century the two chief component parts of the New Testament had taken shape, and the practice of reading apostolic writings in public worship together with the lections from the Old Testament Scriptures was preparing the way for the conception of a Canon of Scriptures of the New Testament. But the New Testament was not yet. Justin (c. 150) is familiar with the four Gospels—though some think that the infrequency of his citations from the Fourth Gospel is not accidental—and with the Pauline Epistles, but when he speaks of Scriptures he means the Old Testament. That Christ has fulfilled the prophecies of the Old Testament is Justin's chief apologetic argument. The full recognition of the Gospels and Epistles as Scripture was hastened by the pressure of heretical movements. Marcion appears to have been the first definitely to conceive the idea of a collection of Christian Scriptures. This was a corollary to his rejection of the Old Testament for which he substituted as a doctrinal authority a mutilated edition of St. Luke's Gospel and of ten Pauline Epistles (not including the Pastorals). The Church was determined to adhere to its inheritance of the Old Testament, but it could not allow itself to fall behind a heretic in the authority it ascribed to the apostolic writings. The reply to Marcion was the construction of a fuller and more authentic collection of apostolic writings, which could be set alongside the Old Testament Scriptures. Another force which by the reaction it occasioned fostered the idea of a fixed Canon of apostolic scripture was the Montanist revival of primitive Christian prophecy. This anti-ecclesiastical and anti-clerical movement with its unregulated and enthusiastic claim to present inspiration was countered by an appeal to apostolic tradition and thus a higher conception of the apostolic writings was encouraged.

It is not improbable that the compilation of the New Testament Canon is due to the deliberate action of the Roman Church. In any case it is certain that by the end of the 2nd century a collection of apostolic documents is generally recognized as authoritative Scripture, and from this time forward the idea of a body of Authoritative Christian Scripture is a presupposition of all theologians. Our most important document for this period is the fragment on the Canon published by Muratori in 1740 and generally known after him as the Muratorian fragment. It is written in Latin and probably emanates from the Church of Rome about the end of the 2nd century. The writer acknowledges a collection of Scripture consisting of the four Gospels, the Acts of the Apostles, 13 Epistles of Paul, two Epistles of John, the Epistle of Jude, the Apocalypse of John and the Apocalypse of Peter. The last is said however to be contested by some. Another prophetic work—the *Shepherd* of Hermas—is excluded from public reading on account of its late date. Writings connected with Marcion, Valentinus, Basilides and Montanus are condemned.

The Christian literature of the end of the 2nd century and the beginning of the 3rd shows widespread agreement as to the nucleus of the Canon: the four Gospels, Acts, 13 Pauline Epistles, and usually Jude, I John or I. Peter are widely attested, though the

last is not found in the Muratorian fragment and was perhaps not in the earliest Canon of the African Church. The Apocalypse of John was generally accepted in the West as being of apostolic authorship, but not accepted in the East. Hebrews and the Epistle of James were usually held to be apostolic and canonical in the East, but not in the West. Alexandria recognized a wider selection: Clement of Alexandria allowed apostolic status to the Epistle of Barnabas, the Apocalypse of Peter, the Epistle of Clement of Rome, and he quotes the *Didache* as Scripture. On the other hand he appears not to have received the Epistle of James, II. Peter and III. John. An important exception to the general practice of the Church is found in the Syriac-speaking Church of Edessa and Mesopotamia. This Church accepted as its Canon the Diatessaron of Tatian with the Acts and the Pauline Epistles. At an early date the Diatessaron was supplemented by a version of the four "separated" Gospels, but the Diatessaron, it seems, retained its place in public worship.

During the 3rd century the great influence of Origen encouraged a wider Canon. He shows acquaintance with all the Epistles which were later recognized, though he expresses hesitation in regard to James, II. Peter and II. and III. John.

The Canon assumed its final form in the course of the 4th century. At the beginning of that century there was still much uncertainty. Eusebius (H. E. iii. 25. 1) describes the situation and divides the books into three classes: (i.) Those which are generally acknowledged, (ii.) those which are disputed but widely recognized, and (iii.) those which are rejected. To the first class belong the four Gospels, Acts, the Epistles of Paul, I. Peter, I John, and, if it is wished (*εἴγε φανεῖν*), the Apocalypse of John; to the second, James, Jude, II. Peter, II. and III. John; and to the last the Acts of Paul, the Shepherd of Hermas, the Apocalypse of Peter, Barnabas, the *Didache*, and, according to some, the Apocalypse of John. Others also reckon the Gospel according to the Hebrews in this class.

The Canon which finally won acceptance first appears in the 39th Festal Letter of Athanasius, A.D. 367. There was great laxity and uncertainty in Egypt as to the exact contents of the New Testament and Athanasius sets out to restore order. His great influence both in East and West secured the victory for his Canon along with the victory of Nicene Christianity. Other traditions held their own for a time. Thus the School of Antioch in general accepted only three Catholic Epistles—James, I. Peter, I. John, while one of its most illustrious representatives, Theodore of Mopsuestia, rejected the whole of this section of the Canon. The Eusebian Tradition represented by Cyril of Jerusalem and Gregory of Nazianzum, was already in virtual accord with Athanasius except that there was hesitation as to the recognition of the Apocalypse.

The West followed the lead of Athanasius. In 382 a synod was held at Rome under Pope Damasus at which the influence of Jerome secured the adoption of a list of books answering to that of Athanasius. This was ratified by Pope Gelasius at the end of the 5th century. The same list was confirmed independently for the province of Africa in a series of synods at Hippo Regius in 393 and at Carthage in 397 and 419 under the leadership of Augustine. It may be noted that though Augustine accepted the canonicity of Hebrews, his manner of quotation shows that he still felt doubts as to its Pauline authorship.

The second Canon of the second Trullan Council of 692, the Quinisextum, may be taken to have formally closed the process of the formation of the Canon for East and West.

The Syriac-speaking Churches had had, as we have seen, a different tradition from that of the rest of the Church. This was superseded by the creation of the Peshittā version, which Prof. Burkitt has shown to have been almost certainly the work of Rabbula, Bishop of Edessa, 411–433. This set aside the Diatessaron and added the three Catholic Epistles, James, I. Peter and I. John. The Philoxenian version of 508 added the other four Catholic Epistles and the Apocalypse, and these were retained in the Harklean revision of 616. These latter versions, however, were confined to the Monophysite Churches, and the Nestorians continued to use the Peshittā.

By the creation of the Canon of the New Testament the Church secured its connection with the creative movement in which it originated. The results have been mixed. The appeal to the classical authority of the apostolic age went along with a depreciation of the sense of present inspiration; and the transformation of the apostolic literature into apostolic scripture entailed an artificial exegesis similar to that which the Jews had already learned to apply to the Old Testament. This often obscured the original meaning of the text in its historical content and it was only after the idea of the Canon had received systematic criticism in the 18th century that a scientific historical exegesis could arise. For the ancient Church, Old and New Testament together came to form "one book" (Origen). But the Church was preserved from some of the most serious evils that wait upon a religion of a book; for the retention of the Old Testament as authoritative Scripture introduced "a wholesome element of complication" into the idea of the Canon. Once formed, the New Testament took precedence of the Old Testament, yet the Old Testament retained its place and its prestige. Lastly, it has been an inestimable gain that through the New Testament Canon the personality of Jesus Christ and the teaching of His greatest apostle have been placed in permanent authority over the Christian Church.

BIBLIOGRAPHY.—B. F. Westcott, *General Survey of the History of the Canon of the New Testament* (first ed. 1855; important revision and additions in 4th ed. 1874, 7th ed. 1896); T. von Zahn, *Geschichte des neutestamentlichen Kanons* (Erlangen 1888-92), an exhaustive examination of the evidence bearing on the history of the use and reception of the books of the New Testament; and *Grundriss der Geschichte des neutestamentlichen Kanons* (1904), a summary statement of the conclusions of the foregoing, with a useful collection of documents; F. C. Burkitt, *Early Eastern Christianity* (1904), Lect. II., The Bible in Syriac; J. Leipoldt, *Geschichte des neutestamentlichen Kanons* (Leipzig, 1907), a full and clear study of the history; A. Souter, *The Text and Canon of the New Testament* (1913); A. Harnack, *The Origin of the New Testament* (trans. by J. R. Wilkinson, 1925), a very suggestive study of the forces which led to the creation of the Canon, containing a criticism of Zahn's presentation of the history.

2. TEXTS, VERSIONS, EDITIONS

(a) **Greek MSS.**—The original autographs of the New Testament books have long since perished, and (except for a few fragments, all from Upper Egypt) the same fate has overtaken all the mss used by Christians in the ante-Nicene period. When in the 4th century the empire became Christian and the Church established, copies of the Scriptures were multiplied in a substantial form—that of the *codex*, i.e., book, on vellum. Two such, dating from the 4th century itself, and each originally containing what was regarded as a whole Bible, survive. Before the 4th century most Christian mss were written on papyrus, and in the earliest times were in the form of a roll (*liber*), or a one-quire book (*uolumen*) like modern booksellers' catalogues. Such mss would contain no more than a single Gospel; rolls were kept with others in a box (*capsa*).

Whole Bibles, even New Testaments (with or without the Apocalypse), were always rather uncommon. Generally the Four Gospels made one volume, the Pauline Epistles another: Acts (with the other Epistles) is sometimes found bound up with the Pauline Epistles, sometimes separate. Counting fragments, there must be some 4,000 Greek mss whose existence has been reported, dating from the 4th century to the invention of printing, the greater number coming from the 11th to the 14th centuries.

The nomenclature of this vast series of books offers many problems. From the 9th century onward most Greek mss. were written in minuscules, i.e., in a character more or less like the Greek of a printed book; before that "uncials" were used, i.e., something like Greek capitals but more rounded (e.g., C, not Σ, Ω not Ω). Since 1751 it has been customary to denote the uncials by capital letters, and the minuscules (also called "cursives") by arabic figures. A much more scientific but very complicated notation has been invented by von Soden, and is used in his edition (*see below*), but it has not come into general use. Yet the old notation has grave defects: the arabic figures are arbitrary, giving no index of the character of the minuscules to which they belong, while the number of uncials has outrun the letters of the

Latin and Greek alphabets, so that the Hebrew alphabet has had to be used. But there is a good case for retaining the old notation, at least for the more important mss. These are not very numerous, and so much has been written about some of them, such as "B" and "D," that it is inconvenient to rebaptize them.

The following are the most important mss. of the New Testament. There is no space here to give descriptions, except where really new information is to be given: for details the reader should consult the editions of Tischendorf or von Soden. von Soden's new numbers are given in brackets.

BIBLES.—

B—Vaticanus (δ1): 4th century.

[Phototype ed., Rome, 1889-90 and 1905.]

Ⲙ—Sinaiticus (δ2): 4th century.

[Phototype ed. by K. and H. Lake, 1911.]

A—Alexandrinus (δ4): 5th century.

[Phototype ed., London, 1879 and 1906.]

C—*Codex Ephraemi Rescriptus* (δ3): 5th century.

[Edit. by Tischendorf (1843).]

GOSPELS AND ACTS:—

D—*Codex Bezae Cantabrigiensis* (δ5): 5th century (*sic*).

[Edit. by F. H. Scrivener (1864); phototype ed. (Cambridge, 1899). The immense literature on this Graeco-Latin ms and its history is admirably discussed by J. H. Ropes in *The Text of Acts* ("The Beginnings of Christianity," vol. iii, London, 1926), pp. lvi-lxxxiv. D was at Lyons in the 9th century, but before that it was used as a Greek Gospel-book. Ropes (pp. lix and lxvii) gives reasons for thinking Sicily a likely place of origin.]

GOSPELS —

W—*Washingtonianus* (εσ14) 5th century.

[Facsimile, Michigan, 1912: full collation and introduction by H. A. Sanders, *The NT mss in the Freer Collection*, part 1 (New York, 1912). W was bought in Egypt by Mr. C. L. Freer (from whom it is sometimes called the Freer Codex) in 1906. Its great interest is its very curious "Western" text in Mark.]

Θ—*Codex Koridethi* (Gregory's 038, v. Soden's 050): 9th century.

[Now at Tiflis. Edit. by G. Beermann and C. R. Gregory, *Die Koridethi Evangelien* (Leipzig, 1913). Θ was written after 873 by a scribe, ignorant of Greek, somewhere in Pontus or Lesser Armenia (*see on cod 565*), with a valuable text, especially in Mark.]

L—*Cod. Regius* at Paris (ε56): 8th century. Various fragments from Upper Egypt, all labelled T. [Noteworthy as showing that Alexandrian texts survived in Egypt long after the Byzantine text was elsewhere dominant.]

PAULINE EPISTLES —

D^{Paul}—*Claramontanus* (Hort's D2, v. Soden's α1026) 6th century.

[Edit. by Tischendorf (1852). Graeco-Latin.]

G^{Paul}—*Boernerianus* (Hort's G3, v. Soden's α1028) 9th century.

[Edit. by C. F. Matthaei (1791). Graeco-Latin, Hebrews omitted.]

H^{Paul}—Fragments at Athos, Paris, etc. (α1022). 6th century.

[Edit. by H. Omont (Paris, 1890); J. A. Robinson, *Euthaliana* (Cambridge, 1895). Oldest witness to the "Euthalian" edition of the Epistles and Acts.]

Minuscules.—Of Greek mss. in minuscules the following are the most important. Certain mss. agree so closely in rare readings that they must be direct or indirect copies of the same earlier codex; they are therefore best cited in groups, e.g., 1, etc., or *fam*¹, stands for the whole group of which codex 1 is the chief representative. The age of the ms. is not given except for special reasons; v. Soden's notation where necessary is added in brackets. 1 etc., or *fam*¹ (*I*⁹ in v. Soden's apparatus, *H*^r in his Introduction) = 1-22-118-131-209-1582-2193. Of these the two most important are 1 (δ 254) and 1582 (ε183). Note that the would-

be decisive list of readings in v. Soden I., p. 1059, is full of serious errors.) Edit. by K. Lake, *Codex 1 of the Gospels* (Cambridge, 1902), but before 1582 was discovered. In any case Codex 1 remains the best member of the family.

28 (ε 168): readings in Tischendorf.

69 etc., or *fam*¹⁸, or "the Ferrar Group" (*It* in v. Soden's apparatus, *J* in his Introduction)=13-69-124-346-543-788-826-828-983-1689-1709. Edit. by T. K. Abbott from W. H. Ferrar's collations (Dublin, 1877); see also Streeter, *Four Gospels*, p. 80. This group must have descended from a very old ms. brought to Calabria before the 12th century. 124 (ε 1211), and after it 69 δ505), are specially valuable within the group.

565 (ε93), Tischendorf's 2nd, Hort's 81: 9th century This splendid ms., written in gold minuscules on purple vellum for (or by) the Empress Theodora, wife of Theophilus (842-56), is textually akin to Θ, with which it is practically contemporary. It also comes from the same region, viz., Kumish-Khane, south of Trebizond. Edit. by J. Belsheim, 1885, corrected by H. S. Cronin (ed. of Cod. N., Cambridge, 1899).

700 (ε133), Scrivener's 604: full collation and Introduction in H. C. Hoskier's *Full Account . . . of Codex 604* (London, 1890).

Other minuscules, such as 33 (δ48), 157 (ε207), 579 (ε 376), are worthy of mention as having a text akin to κ and B, but the list here given has been selected to include the codices which have ancient elements of text not preserved elsewhere.

A few words must be said on the early Papyrus fragments of N.T. books discovered in the past 40 years. They all come from Upper Egypt, mostly from Oxyrhynchus, where the soil is dry enough to preserve perishable material. Most, of course, are so small in size that they present little textual material. The following stand out as of special interest:—

1. *Oxyrhynchus Pap.* 2: Matt. i. 1-9, 12, 14-20 (late 3rd century).

2. *Oxyrhynchus Pap.* 208 and 1228: fragg. of John i., xv., xvi., xx. (3rd century).

3. *Michigan Pap.* 1578: Matt. xxvi. 19-52 (3rd century).

4. *Michigan Pap.* 1571: Acts xviii. 27-xix. 6, 12-16 (3rd century).

5. *Oxyrhynchus Pap.* 405: Irenaeus, *c. Haer* iii. 9 (early 3rd century).

No 2 is probably the oldest surviving Christian *uolumen*, i.e., it contained the Gospel of John arranged in a single quire, like a bookseller's catalogue. Nos. 1 and 2 give general support to the κ B text, No. 3 seems to have a greater tendency towards "Western," i.e., D, readings, but neither 1, 2 or 3 have Byzantine readings. No. 4 is specially noteworthy, in that it was published and dated before its connection with Irenaeus was perceived. Irenaeus wrote in A.D. 180, so this scrap comes from a ms. written only 30 or 40 years later (see the revised text in *Ox. Pap.*, vol. iv. p. 264). The fragment gives Irenaeus's quotation of Matt. iii. 16 f. in a text that agrees with D and α against other mss., and against the Latin translation of Irenaeus.

Quite distinct from these fragments is the Papyrus Book, containing Acts and some O.T. Books in Sahidic, dating from about A.D. 300 (edited by Sir E. W. Budge, London, 1923). The text is incorporated in Horner's ed. (see below).

BIBLIOGRAPHY.—See the editions given above under each item.

(b) **Versions.**—For about 80 years, from A.D. 70 to 150, almost all Christians were Greek-speaking subjects of the Roman empire. At the close of the period Christianity reached the Latin-speaking regions of Roman Africa and the little independent principality of Edessa (*q.v.*), beyond the Euphrates. Very soon afterwards Latin and Syriac versions of the newly collected New Testament Scriptures appear. These versions stand in a class by themselves for antiquity and critical importance, for in other countries (such as Egypt and Palestine) Christianity long remained a Greek-speaking cult and no written versions were made into what was regarded as the barbarous patois of provincials.

1. **Latin Versions.**—No tradition about the date, place or authorship of the first Latin versions survives. It is possible that the first rendering of any part of the New Testament into Latin was a Harmony of the Gospels, an early form of Tatian's Diates-

saron (see **TEXTUAL CRITICISM**); what is certain is that the Scillitan Martyrs at Carthage (A.D. 180) had in their box of rolls "letters of Paul, the just man," which were not likely to be in anything else but Latin. By Tertullian's day, whose writings are dated from 20 to 40 years later, the whole Bible seems to have been extant in Latin, but Tertullian himself often translated directly from the Greek: he never shows that respect for the Latin text usually accorded to a vernacular rendering of some age. Cyprian, on the other hand, writing between 240 and 250, quotes the Latin Bible consistently and accurately. It may therefore be inferred that the New Testament was rendered into Latin, probably at Carthage, in the last third of the 2nd century.

Fragments of the Latin version used by Cyprian survive in Cod. Bobiensis (*k*), now at Turin, which contains the latter half of Mark followed by the first half of Matthew; and in the Fleury Palimpsest (*h*), now at Paris, which contains fragments of the Apocalypse and of Acts. Cod. Palatinus (*e*), formerly at Vienna, now restored to Trent, containing the latter half of Matthew, nearly all of John and Luke, and fragments of Mark, is of the same family but more assimilated to the European standard. (The class mark of *k* is G vii. 15: it was much damaged by damp in the great fire of 1904: phototype ed., Turin, 1913.)

In Cyprian's correspondence some letters come from Rome. The Biblical quotations in these differ perceptibly from those of Cyprian himself, and approach those of 4th-century writers such as Lucifer of Cagliari. By the middle of the 3rd century, therefore, the Church of Rome, now become a Latin-speaking community, had a version of its own. To this version, commonly called the "European Latin" to distinguish it from the "African," i.e., Cyprianic, text, are assigned the remaining "Old-Latin" codices; of the Gospels there are some dozen, not counting small fragments (list below), including the Latin side of D. Only one fragmentary ms. of the Pauline Epistles survives besides the Latin sides of D^{Paul} and G^{Paul}, but Acts and Apocalypse are represented, and there are some late non-Vulgate texts of most of the Catholic Epistles.

The mss. of the "European"-Latin differ much among themselves, but all seem to descend from the same stock, which is more like a revision of the "African"-Latin than a fresh independent translation. These differences were noted late in the 4th century and Pope Damasus commissioned the great scholar Jerome to draw up a standard revision. The Gospels were completed in A.D. 383 and the new revision rapidly found favour, even in Africa: at Hippo under Augustine in 404 the Gospels were publicly read from Jerome's revision, while for Acts the unrevised "African"-Latin was retained. In other countries, notably north Italy and parts of Gaul, the revised version made much slower progress. By the time of Gregory the Great (d. 604), however, Jerome's revision was everywhere used, except in so far as Old-Latin readings survived in imperfectly corrected codices. From its use ever since the 7th century Jerome's revision is known as the Vulgate, in contradistinction to the new renderings made from the Greek in the 16th century.

Short list of Old-Latin mss. of the Gospels, with dates, with the regions they may be held to represent, and the name of their editors.

a	Vercellensis, iv	N. Italy	Irico, 1748
b	Veronensis, v or vi	"	Bianchini, 1749
c	Colbertinus, xii.	(mixed text)	Belsheim, 1888
d	Latin side of D, v.	? Sicily	Scrivener, 1864
e	Palatinus, v.	Africa, N. Italy	Tischendorf, 1847
ff	Corbiensis II., v.	Gaul	E. S. Buchanan, 1907
f	Brixianus, vi.	Gothic Lombardy	Bianchini, 1749
h	Claromontanus, vi.		
	(Matt.)	Gaul	Belsheim, 1892
i	Vindobonensis, v. or vi	? Lombardy	Belsheim, 1885
	(Luke, Mark)		
k	Bobiensis, iv.		
	(Mark, Luke)	Africa	Sanday, 1886
l	Rehdigeranus, viii.		
	(Luke) Matt.	Lombardy	Haase, 1865-66
n	S. Gallensis, v. (fragg.)	N. Italy	H. J. White, 1886
q	Monacensis, vii	? Gothic Italy	H. J. White, 1888
r	Usserianus I., vi. or vii	Ireland	T. K. Abbott, 1884

There are several other smaller fragments. *f* is much influenced by the Gothic version, *q* occasionally so. *h* only contains Matthew. *l* contains all four Gospels but is only Old-Latin in Luke: the same is nearly true of *i*. The late ms. *c* is European in Matthew: there are many Vulgate readings throughout, especially in John, but in Mark and Luke *c* has a large African element.

The mss. from the rest of the N.T. are mentioned in the text. Add: D. de BRUYNE, *Les Fragments de Freising (r)* (Rome, 1921).

BIBLIOGRAPHY.—P. Sabatier, *Bibl. Sacror. Lat. Versiones Antiquae*, vol. iii. (Paris, 1751); a collection of Latin Patristic quotations, still indispensable. J. Wordsworth and H. J. White, *N.T. . . . Latine* (Oxford, 1889-); the only critical edition, with various readings, of the Vulgate N.T., still in preparation by Dean White. 1. For the early history of the Vulgate: S. Berger, *Histoire de la Vulgate* (Paris, 1893); J. Chapman, *Notes on the early History of the Vulgate Gospels* (Oxford, 1908). 2. For the Old-Latin: W. Sanday, *Old-Latin Biblical Texts*, No. II. pp. xlii-clxvi., 1-53 (fundamental); F. C. Burkitt, *The Old Latin and the Itala* (Cambridge, 1896); see also *J. Theol. Studies*, xi., pp. 258-268, 447-458 (1910), also *Miscellanea Amelii*, pp. 25-41 (Montecassino, 1920); D. de Bruyne, *Quelques Documents (Sommaries africains)*, *Revue Bénédicte*, pp. 221-227, April 1911. 3. For Codex Bezae: J. H. Ropes, *The Text of Acts* (London, 1926). 4. For the Latin Diatessaron: E. Ranke, *Codex Fuldensis* (1868); J. Bergsma, *Bibliothek van middelnederlandsche Letterkunde* 54, 55, 61 (Leyden, 1895-98); D. Plooij, *A Primitive Text of the Diatessaron* (Leyden, 1923); F. C. Burkitt, *Tatian's Diatessaron and the Dutch Harmonies*, *J. of Theol. Studies* xxv., pp. 113-130 (Jan. 1924).

2. **The Diatessaron and Early Syriac Versions.**—The Gospel, according to Syriac tradition (*Doct. of Addai* 36), came to Edessa at the hands of Addai in the form of the Diatessaron, and the extant remains of early Syriac literature show that it was in a Harmony that the Gospel chiefly circulated among Syriac-speaking Christians prior to A.D. 411. The compiler of the Diatessaron, according to Eusebius, was Tatian, a disciple of Justin Martyr: after Justin's death Tatian returned to his native Mesopotamia and there evangelized (Epiphanius, *Haer.* xlii. 1). It is in the opinion of the present writer probable that the *Addai* of Syriac tradition, who evangelized Edessa and introduced the Diatessaron, and the *Tatianos* of Eusebius and Epiphanius, who compiled the Diatessaron and returned to his native Mesopotamia before A.D. 170 are one and the same, Addai being Tatian's native Semitic name as Shā'ul was St. Paul's.

Besides the Diatessaron the four separate Gospels were translated into Syriac, probably about A.D. 200. Of this translation two mss. survive: the Sinai Palimpsest (4th century), discovered by Mrs. A. S. Lewis at the Convent of St. Catharine on Mount Sinai in 1892, quoted as Syr. S; and Cureton's ms. (early 5th century) from the Nitrian collection in the British Museum, quoted as Syr. C. These mss. differ considerably in reading, and each has certainly been influenced by the Diatessaron, so that in Syriac-speaking lands about A.D. 400 the Gospel was extant as a Harmony and as "separated Gospels" (in Syriac *Evangelion da-Mepharreshē*), the single copies having many discordant readings, just as had been the case in Latin before Jerome. To remedy this, Rabbūla, bishop of Edessa from 411 to 435, prepared a revised edition of the "Separated Gospels," freely correcting the text from Greek mss. such as were then current at Antioch: this edition he established by authority and suppressed the Diatessaron, with such success that no Syriac copy of the Diatessaron survives, and of the unrevised version only Syr. S and C. Rabbūla's revision is now used by both the great divisions of the Syriac-speaking Church (the Jacobites and Nestorians): to distinguish it from the elaborate later revision of the (Jacobite) Old and New Testament it is usually called Pēshittā, i.e., the simple version. For modern criticism Syr. S and Syr. C are among the half-dozen primary authorities; the Pēshittā has only the value of a post-Nicene revision.

An Arabic translation of the Diatessaron survives, translated from a form of the Syriac in which the wording had been almost completely assimilated to the Pēshittā, whereas the quotations of Ephraim (d. 373) show that the wording in ancient time had been more like that of Syr. S and C: in the processes of revision and of translation into Arabic many characteristics of the original must have disappeared. But the general arrangement of the Gos-

pel mosaic has been well preserved, as we see from agreements in order with Ephraim's Commentary on the Diatessaron (extant in an Armenian translation only), which are enough to demonstrate that this Syriac Harmony is distinct from the Latin form of the same work, though akin to it (see further on TEXTUAL CRITICISM).

No ms. of the pre-Pēshittā Syriac of the Acts or Epistles survives. For the Acts we have the Armenian translation of Ephraim's "Commentary," which is little more than an abridged paraphrase, almost worthless for textual purposes. For the Pauline Epistles we have many quotations in Aphraates (A.D. 345) and the Armenian translation of Ephraim's Commentary, which contains some valuable information, though the Armenian translator in too many cases has rendered Ephraim's quotations by the equivalent words of the Armenian vulgate. The only Catholic Epistles received in the Syriac-speaking Church before Rabbūla's revision were I. John and I. Peter, to which Rabbūla added James.

The Pēshittā N.T. is extant in many mss., some actually of the 5th century. All present the same text with hardly any various readings.

BIBLIOGRAPHY.—F. C. Burkitt, *Evangelion da-Mepharreshē*, 2 vols. (Cambridge, 1904) [contains the texts of Syr. C and S, with full introduction]; A. S. Lewis, *The Old Syriac Gospels* (London, 1910) [contains the text of Syr. S with apparatus, etc.]. For the Pēshittā, G. H. Gwilliam, *Tetraeuangelium Sanctum* (Oxford, 1901) [Gospels, with apparatus of mss.]; *The N.T. in Syriac*, Bible Society (London, 1905-20) [Syriac text only]; N.T. with Psalter, in Nestorian type (New York, 1886 and often reprinted) [almost as good]. For the Arabic Diatessaron, A. Ciasca, *Tatiani Evang. Harm. Arabice* (Rome, 1888); J. Hamlyn Hill, E. Trans. in *The earliest Life of Christ* (Edinburgh, 1894).

3. **Other Versions.**—*Egyptian* (or "Coptic") versions date from the last half of the 3rd century: before that Christianity appears to have been confined to Alexandria and a few Greek-speaking towns, such as Oxyrhynchus. There are two main versions, Sahidic, i.e., that current in *es-Sa'id*, Upper Egypt, and Bohairic, i.e., that current in the *Behēra*, S.E. of Alexandria. Mss. in other dialects (Fayyumic, Akimic) are found, but textually belong to the Sahidic. The Bohairic version dates from the Coptic revival of the 7th century, when the Greeks had been turned out by the Arabs: it seems to have been based on old Coptic materials, and is one of the purest representatives of the "Alexandrian" text. The Sahidic is of much the same character, but here and there a "Western" element comes into view, that may belong to the most ancient stratum of the Coptic versions.

BIBLIOGRAPHY.—G. Horner, *N.T., Bohairic*, 4 vols. (Oxford, 1898-1905), *Sahidic*, 7 vols. (Oxford, 1911-24). For the date of the Egyptian versions see I. Guidi, *Nachrichten von der K. Ges. der Wissenschaften*, pp. 49-52 (Göttingen, 1889); also *Ency. Biblica*, col. 5,008 f.

The Armenian nation, together with its king, Tiridates III., became Christian about the year 300: somewhere about that date the first Armenian version seems to have been made, apparently from the Old-Syriac. This original version was revised from the Greek by Mesrob about 400, but traces of the Syriac are still evident (see J. A. Robinson, *Euthaliana*, pp. 76-91). It was from this earlier Armenian version that the Georgian (or Iberian or Grusinian) version was made, the oldest codex of which (dated 897) is said to present it in a very pure form.

The critical value of both the Georgian and Armenian versions is therefore the help they give towards better knowledge of the Old-Syriac version: when the Georgian N.T. has been critically edited it is likely to take a high rank for that purpose. Most Armenian mss. represent substantially the same text, viz., the mixed one resulting from Mesrob's revision. The most interesting ms. known is the Etchmiadzin codex of A.D. 989 discovered by F. C. Conybeare, which contains the Longer Conclusion to Mark (omitted by most old Armenian mss.) with the heading *Ariston Eritzu* ("of the Presbyter Arist[i]on"), and a peculiar recension of the *Pericope de Adultera* ([John] viii. 1-11).

BIBLIOGRAPHY.—J. Zohrab, *New Test.* (in Armenian) (Venice, 1789, reprinted with O.T., 1805). On the Armenian version, see J. A. Robinson, *Euthaliana*, pp. 72-98 (Cambridge, 1895). On Georgian Literature (including the N.T.) see R. P. Blake, *J. Theol. Studies* for Oct. 1924, vol. xxvi., pp. 50-64.

The *Gothic* version was made by Ulphilas (*Wulfila*), the apostle of the Goths, in the 4th century. It is the earliest surviving literature in any Teutonic language, and at the same time the earliest witness for the Byzantine text. Of the N.T. the Gospels and the Pauline Epistles (without Hebrews) survive, but with many gaps. Ulphilas worked among the Goths of the Danubian Provinces, but the surviving documents all belong to north Italy and the times of the Ostrogoths and Lombards. The chief critical importance of the Gothic version is the influence it had on certain codices usually reckoned as Old-Latin, notably *f*, and perhaps *g*.

A fragment of a bilingual Gothic-Latin codex containing a few verses of Luke xxiii. and xxiv. turned up at Antinoë in Egypt in 1908 and is now at Giessen (see *Streitberg*, vol. ii., p. 312).

Ethiopic is the name given to Ge'ez, the classical language of the Abyssinians. Abyssinia became a Christian nation in the 4th century, and the Ethiopic version of the N.T. undoubtedly goes back to that period, but the existing mss. which are all late, have been much revised, chiefly from the Arabic version current in Egypt in the 13th century, when the Abyssinian Church was reorganized. It is this late revised text which has been printed, the only ancient piece of the older form being Matt. i.–x. as edited by Hackspill. Even in the revised text many relics of ancient readings are found, some possibly reflecting an early stage of Syriac-speaking Christian missionaries, but all readings agreeing with the (printed) Arabic version must be held to have little authority.

[A very good translation from the text in the London Polyglot of 1657.] I. Guidi, *Le Traduzione degli Evangelii in Arabo e in Etiopico* (Rome, 1888); L. Hackspill, *Z. für Assyriologie*, xi., pp. 117 ff. and 367 ff. (1896).

The *Harclean Syriac* was made in A.D. 616 by Thomas of Harkel (or Heraclea), bishop of Mabbog and one of the Monophysite exiles who lived in Egypt after the deposition of Severus of Antioch. Like other writings of the same school of translators Thomas follows the Greek with pedantic literalness, so that it is particularly easy to ascertain what Greek text he followed. For the most part this is the ordinary Byzantine vulgate, but in Acts he used in addition to his usual authority another exemplar which was full of very valuable "Western" readings, which he inserted sometimes in his text, sometimes in the margin (see Ropes's *Acts*, especially pp. clvi. n., clxxviii. f.). Thomas's work was based on a revision of the Syriac N.T. by Philoxenus of Mabbog, the greater part of which (if it really consisted in more than additional tables of contents, etc.) is no longer extant. What survives is the text of those parts of the N.T. not included in the Peshittā, viz., the four minor Catholic Epistles and the Apocalypse, all of which have been edited by J. Gwynn.

BIBLIOGRAPHY.—J. White, *Versio Philoxeniana (sic, i.e., "Harclean")*, Oxford, 1778–1803 (all the N.T. except Apocalypse; the missing end of Hebrews was supplied by R. L. Bensly, Cambridge, 1889). J. Gwynn, *The Apocalypse in Syriac, i.e., the true Philoxenian* (Dublin, 1897); *Remnants of the Later Syriac Versions*, Minor Epistles, etc. (London, 1909). Ordinary modern editions of the Peshittā give these Minor Epistles (II. Peter, II and III. John, Jude) from the Philoxenian as first published by E. Pococke in 1630, and the Apocalypse from the Harclean as first published by L. de Dieu in 1627.

Palestinian Syriac (or "Jerusalem" Syriac) is the name given to the Christian ecclesiastical literature in the vernacular Aramaic of Palestine. This literature is not old. It seems to owe its origin to the efforts of Justinian in the 6th century to root out paganism and Judaism from the country districts of the Orient. The surviving documents reflect the usages of the Greek-speaking Church of Jerusalem: they include a Lectionary of the Gospels, and another from other books; also fragments of the continuous text of most N.T. books. The text attested is a curious variety of the Byzantine, with some elements due to the Peshittā, and perhaps some relics of the ancient text of Caesarea.

BIBLIOGRAPHY.—A. S. Lewis and M. D. Gibson, *The Palestinian Syriac Lectionary of the Gospels* (London, 1899); and *A Pal. Syriac Lect. cont. Lessons from the Pentateuch*, etc. (London, 1897); J. P. N.

Land, *Anecdota Syriaca*, vol. iv. (Leyden, 1875); H. Duensing, *Texte und Fragmente* (Göttingen, 1906). See also F. C. Burkitt, *Christian Palestinian Literature*, *J. Th. Stud.* ii., pp. 174–185 (Jan. 1901), and *The Old Lectionary of Jerusalem*, *J. Th. Stud.* xxiv., pp. 415–424 (July 1923).

Arabic versions must be noted at the end, though none of them are older than the 8th century: their only critical importance is the influence they have exercised since the 13th century upon the much older Ethiopic version.

(c) **Editions.**—The editions of the Greek Testament here listed are those which for one reason or other were landmarks in the study of the text.

Erasmus (Basle, 1516): the actual first edition.

Complutensian Polyglot, printed 1514–17; published 1520.

Stephanus (i.e., Robert Étienne), ed. 3 (Paris, 1550). This edition, which in all essentials follows Erasmus, gave what was till the time of Lachmann the received text (hence the symbol *σ*, i.e., *σ* for Stephanus). The Elzevir editions of 1624 and 1633 are reprints of Stephanus with a few errors and corrections. Full details of the minute differences between these editions are given in H. C. Hoskier's *Full Account of Cod. 604 (= 700)* (London, 1890).

J. Mill (Oxford, 1707): the first large collection of various readings.

J. J. Wetstein (Amsterdam, 1751): a still larger collection of readings, and a very valuable collection of illustrative parallels, especially from classical authors.

K. Lachmann (Berlin, 1842–50): the first thoroughgoing attempt to construct a text from ancient authorities alone, uninfluenced by printed editions. It took a scholar of Lachmann's calibre to make this, to us obvious, advance. Karl Lachmann is the famous editor of Lucretius: it was his study in *Studien und Kritiken* for 1835 (repeated in the Preface to vol. ii of his N.T., 1850) that set the doctrine of the priority of Mark to Matthew and Luke on a firm philological foundation.

C. Tischendorf (8th ed., Leipzig, vol. i., 1869; vol. ii., 1872; vol. iii. [Prolegomena by C. R. Gregory], 1894). This edition was, until v. Soden's appeared, the largest collection of various readings. Tischendorf's text is rather capricious, but his notes are a model of clearness and compression combined, so that the work is still indispensable to the textual student.

Westcott and Hort (London, 1881–82). Vol. ii., containing the Introduction (reprinted 1896), was written by Dr. F. J. A. Hort, but the work is usually quoted by the symbol WH. Hort recognized three main families: the *Antiochian* or Constantinopolitan, to which belong most Greek mss. and the later versions (Gothic, Slavonic, etc.); the *Western*, to which belong D, the Old-Latin and the Old-Syriac versions; and the *Alexandrian*, to which belong many of the older Greek mss. (especially such as seem to have an Egyptian origin), and also the Egyptian versions, particularly the Memphitic (now called Bohairic). The Western family represents the careless, unrevised and often interpolated state of the text in ante-Nicene times; the Antiochian family is a smooth and plausible revision, made probably by the martyr Lucian of Antioch and adopted by the Church in the new royal city of Constantinople; the Alexandrian family is a comparatively pure form of text approved by the more careful Alexandrians, and is characterized mainly by minute scholastic emendations. Besides these a few very old documents exist, which attest a text not indeed perfect, but belonging to neither of the three main families: this text (or texts) Hort calls *Neutral*. Its most consistent representatives are B and *Δ*, particularly B, so that Hort's text in the main is not unlike a corrected transcript of "Codex Vaticanus," which he refused to the end to regard as specially connected either with Alexandria or Caesarea.

The weak point in Hort's theory is the failure to incorporate B and *Δ* into the Alexandrian phalanx, to which they obviously belong, whether or no we connect B and Alexandrians, as Bousset

(1894) and v. Soden do, with the recension of Hesychius (about which we know nothing but the name). In this connection it should be borne in mind that the actual attestation of the text approved by Hort is only rarely that of * or B alone: it usually has support from the Old Syriac or Old Latin documents, *i.e.*, from some of the "Western" group, and so Hort called B "Neutral," meaning unlocalized.

For modern views, including B. H. Streeter's, *see* below on *Textual Criticism*, where note that what is there called "Byzantine" is Hort's Antiochian and what is called "Alexandrian" is Hort's Alexandrian and Neutral.

The edition of *Hermann v. Soden* (Berlin, vol. i. [Introduction], 1902-10; vol. ii. [Text and full Apparatus], 1913): this was an ambitious attempt to supersede Tischendorf in giving a complete conspectus of variants, including the newest discoveries, together with a new textual theory which necessitated a totally new notation for the documents. The new notation is almost incomprehensible in actual use, except to specialists, the textual theory has not commended itself to scholars, either in Germany or elsewhere, and there are grave inaccuracies in certain parts of the work, *e.g.*, vol. i., p. 1,059, which destroy confidence in statements about readings which otherwise cannot be controlled. It is therefore a work for specialists alone. Tribute must be paid to the immense industry of the large staff of workers, who have at least examined all the known Greek mss. whether in Europe or the Orient. Little of first-rate importance indeed has been brought to light in v. Soden's pages alone, for the full and most accurate presentation of new discoveries such as W and Θ must be sought elsewhere in separate publications. The outstanding merit of the work consists in this, that the investigator is never quite confident that he has mustered all the evidence for and against a given reading until he has verified his statements by consulting "von Soden."

3. TEXTUAL CRITICISM

The Textual Criticism of the New Testament has for its primary object the reconstruction of the original text from the Greek mss. versions and quotations in early writers described above. A secondary object is to trace the history of the text, to identify and characterize the various editions or recensions current in different times or localities. It is noteworthy that till the invention of printing neither in the original Greek nor in Latin was a complete uniformity of text arrived at, notwithstanding the authority ascribed to the words by ecclesiastical theory. Only in Syriac was uniformity reached.

A leading cause of this remarkable state of things must be sought in the very extensive variations which were current in early times, particularly in the Gospels. Apart from some half-dozen remarkable readings (such as the omission of "in Ephesus" in Eph. i. 1) the text of the Pauline Epistles resembles that of most ancient works: there are plenty of scribes' errors, etc., and the mss. fall into groups as is natural, but the variations are of small account and are mostly explicable from the context. In a word, the variations are *accidental*. In the Gospels, on the other hand, the characteristic variations are *intentional*, such as the addition or insertion of whole passages, some of which must certainly have been supplied from an external source. The longest is the whole story of the Woman taken in Adultery, inserted between John vii. 52 and viii. 12; others are a long insertion after Matt. xx. 28 (61 words), the saying about the Face of the Sky in Matt. xvi. 2-3 (31 words), the story of the Angel and the Bloody Sweat in Luke xxii. 43-44 (26 words), and many other shorter passages. No satisfactory palaeographical explanation has ever been found for these variants; they are evidently made on purpose, by persons who had new matter to insert into the text and felt themselves at liberty to do so. The fact of the occurrence of these longer interpolations (as they are usually called) prepares us to find that very many of the shorter variants are of the same nature, *i.e.*, that they did not arise through scribal errors but by intentional efforts to improve or enrich the original. It is further evident, from the general course of ecclesiastical sentiment, that such violent modifications of what was regarded as Sacred Scripture must have

taken place very early. Blunders may occur at any time, with whatever reverence a text is regarded; efforts to remove minor stumbling blocks, such as differences in parallel narratives, may have been made in later times, with the naive idea that the less familiar wording was itself a scribal error. But the longer insertions, whether genuine additions to the Gospel History or not, must have come from sources literary or oral of which there is no trace in later times. In other words, both the longer and the shorter texts must go back into the 2nd century.

This is certainly true of the most important variations of all, *viz.*, those connected with the end of the Gospel of Mark. The two oldest Greek mss. (A and B), the better ms. of the Old-Syriac version (Syr. S), and some other authorities, end at xvi 8 (ἐφοβούμετο γὰρ); the oldest and best Latin text (K), with some secondary support, adds a short sentence evidently intended to round off this abrupt conclusion; the great majority of our authorities, including W (5th century) and also Irenaeus (A.D. 180), possibly also Justin Martyr, *Apol.* i. 42 *fin.*, 45 (A.D. 153), attest the Longer Conclusion (Mk.) xvi. 9-20. The sentence (the so-called Shorter Conclusion) runs as follows: "But all the things which they had been commanded they also declared shortly to those with Peter. After these things Jesus himself also appeared, and from the East even to the West sent by them the holy and incorrupt tidings of eternal salvation. Amen." It is obvious that these variations imply a mutilated archetype, preserved in some branches of transmission with singular fidelity, and edited in others to supply an obvious defect.

The Gospels.—The *Gospels* thus form a textual problem by themselves. The few statements about the history of the text and various readings in early Christian writers being obscure and perhaps inaccurate, the best critical weapon is what is called the evidence of groups. In the last resort the appeal is to internal evidence: the groups or even single authorities which in repeated instances give the fresher, less conventional, readings are to be trusted in cases where the originality is less obvious.

A text formed by choosing intelligently between the readings attested by AB, by K, and by Syr. S—neglecting all other authorities—would differ little from the best that can be constructed. But if we are to get an idea of the history of the text, and the forms in which it was read in various regions in ancient times we must make a wider induction. If all the readings of all our authorities be tabulated it soon becomes evident that they fall into three main groups, for which the most convenient names are Byzantine, Alexandrian and "Western." The *Byzantine* group is that of the majority of the Greek mss. if you construct a text of the Gospels by always accepting the reading of the majority, the result would be the Byzantine text. With it would generally agree the later versions, such as the Slavonic and the Gothic; the Latin Vulgate (A.D. 383) and the Syriac Peshitta (A.D. 411) would often, but not consistently, agree also. The *Alexandrian* group contains A and B, sometimes with a few other Greek mss., and often with the Egyptian versions. The most consistent support of the *Western* group comes from the Old-Latin versions (K, C, A, B, F, etc.) together with D, a codex certainly written in the West; the two Old-Syriac mss. (Syr. SC) also very often support characteristic "Western" readings, and they are often attested by some later Greek mss.

The *Byzantine* text is found in the quotations of the Greek ecclesiastical writers from Chrysostom (400) onwards, the *Alexandrian* text in Egyptian writers as early as Origen (c. 215); it is of fundamental importance to observe that in all earlier Greek writers, including Clement of Alexandria, the Gospel quotations are (a) generally allusive and inaccurate, (b) "Western" in character.

It must further be remarked that while the Byzantine and Alexandrian texts are definite entities, easily constructible by the general agreement of their most consistent supporters, the "Western" texts differ widely among themselves. Moreover, the triple division above spoken of coalesces in most variations into two texts. That the three groups do exist as groups is proved by the occurrence of "ternary variations," *i.e.*, where there are three readings attested severally by the Byzantine, the Alexandrian and

the "Western" groups, e.g., Matt. xxii. 13. To this class belong Hort's "conflate" readings, where an Alexandrian and a Western reading is combined in the Byzantine text (*Hort* § 134-149), e.g., the last words in Luke. But very often Byzantines and Westerns stand together against the Alexandrians, also Byzantine and Alexandrians against Westerns; not infrequently also the Alexandrian group attesting a given reading is reinforced by important "Western" authorities.

The chief inferences to be drawn from these facts are:—(1) The Byzantine text is a recension properly so called, the form in which the Gospel was introduced into the new Christian metropolis of Constantinople; it was an eclectic fusion of texts previously current, and contains hardly any ancient element not better preserved elsewhere. (2) The Alexandrian text seems to have some connection with the great Christian scholar Origen, who (so far as we know) was the first to pay attention to the exact wording of the Gospels and to make any comparison of mss. (3) The "Western" text is not exclusively Western in the geographical sense, nor is it a single definite recension; it is more accurate to say that "Western" readings represent the variegated and uncorrected state of the text in the ante-Nicene period, especially from about A.D. 150 (when the Gospels were first collected together into a common corpus) until the time of Constantine.

Modern textual investigation is mostly connected with this mixed crop of "Western" readings, so as to sort them out into significant groups, whereby we may not only have better criteria for ascertaining the original in cases of doubt, but also get some idea of the kind of text current in various regions in early times. The most fruitful of these investigations in the last few years has been that of B. H. Streeter, whose book, *The Four Gospels* (London, 1924), treats of textual criticism at length. Dr. Streeter recognizes three divisions in the so-called "Western" group: there is the true Western text (=D W^{mk} lat-afr lat-eur), the Old-Antiochian text (=Syr. S and C), and what he has called the Caesarean text (Θ-565, 1 etc., 69 etc., 28, 700). It should be noted that Streeter recognizes that all the witnesses to his Caesarean text have often been assimilated to the Byzantine standard. Strictly speaking, therefore, the attestation consists of the readings of Θ etc. which differ from the Byzantine. The cornerstone of his construction is his demonstration that whereas Origen in the earlier parts of his Commentary on John, written in Alexandria, is a consistent witness to the text of α B, nevertheless in the latter parts of the same work and in his Commentary on Matthew, written after he had removed to Caesarea in Palestine, his quotations attest a text more like that of Θ and its allies. Streeter concludes from this that B represents the local text of Alexandria about the year 200, while the non-Byzantine readings of Θ and its allies represent the text current at Caesarea early in the 3rd century.

In the opinion of the present writer the weak point in Streeter's attractive theory is that the "interesting" readings of Θ-565, 1 etc., 69 etc., 28, 700, are regarded as fragments of *one* text, which nevertheless is separated from the Old-Syriac version with which they (particularly 1 etc., and 28) have much in common. (See e.g., Mark ii. 27, iii. 17, vi. 22 f., x. 11 f.; viii. 10 [τὸ ὄρος W 28=Syr. S]). It is noteworthy that the whole "Western" phalanx does occasionally go wrong together, as when in Mark vi. 53 καὶ προσωμίσθησαν is omitted by D W Θ-565, 1 etc., 28, 700, 983, α b c ff i q r, Syr. S vg arm: see *J. Theol. Studies*, xvii p 19 (Oct. 1915). It seems better to take the readings of Θ, etc., together with those of Syr. S C, as representing variants current in the East, just as the often discordant but yet very nearly connected readings of D and the various branches of the Old-Latin represent the state of the text in the West about A.D. 200 in its considerable but not unlimited variety. Some errors were very widely spread, others (though ancient) seem to have had always a limited circulation. It is a vain hope to imagine that we can arrive at the original text by constructing the Alexandrian, the Old-Western, and the Old-Eastern texts, and then accepting the agreement of either two against the other.

Two special points may be noticed here. For those who are convinced that Mark is the actual source of Matthew and Luke

there is a difference of interest between the various readings in the text of Mark and those in the parallel passages of Matthew and Luke. A change of text in Mark may conceivably alter our view of the thing narrated: if "to the other side" in Mark vi. 45 be omitted (so W 1 etc., Syr. S), or "through Sidon" be read instead of "and Sidon" in Mark vii. 31, the whole course of the itinerary of Jesus is altered. On the other hand the omission or retention of Matt. xvi. 2-3 is a matter of merely literary interest: the authority for what happened on the occasion in question, both for ourselves and for "Matthew," is Mark viii. 10-13, and whether it was Matthew or a later editor who thought that the Saying about Weather could be introduced at that particular place is a secondary consideration. The other point is very well treated by Dr. Streeter in chap. xi. of *The Four Gospels*: it concerns the few and relatively insignificant agreements of Matthew and Luke against Mark, in which Streeter shows that almost all the cases not otherwise accounted for may be reasonably explained as harmonistic scribal alterations in the text, from which either the Old-Latin or the Old-Syriac, or both, have generally escaped.

Some Continental scholars, notably v. Soden, regard Tatian's Diatessaron (see above) as a prime cause of harmonistic readings: we know of this Gospel Harmony in two forms, (a) in Latin, (b) in Syriac. In Syriac, as explained above, it certainly played a great part; according to tradition the Gospel reached Edessa in the form of the Diatessaron, and the extant remains of Syriac literature before A.D. 411 show that the separate Gospels were much less used than this Harmony. It is not surprising, therefore, that the text of Syr. S and C, the two surviving mss. of the pre-Peshitta Syriac, should often exhibit harmonistic readings, many of which were no doubt due to the influence of the Diatessaron. In Latin there survives Codex Fuldensis (a ms. corrected in the year 546 by Victor, bishop of Capuá), and also four Dutch Harmonies of the 13th and 14th centuries, their Latin original being closely connected with *Fuld* in text but not apparently derived directly from it. The wording in all these has been almost entirely assimilated to the Vulgate, but there are sufficient relics of Old-Latin renderings to show that the Harmony must have existed in pre-Vulgate times in Latin, with a text akin to lat-eur. There is little sign of its use by Latin Fathers, and its connection with Tatian is only inferred from a learned guess of Victor's, probable in itself but not traditional. The arrangement of the Gospel mosaic in the Latin and Syriac texts is so much alike as to demonstrate their kinship, but sufficiently different to make it improbable that the Old-Latin parent of *Fuld* was a translation from the Syriac. No tangible evidence of a Greek Diatessaron has appeared.

It is not likely, therefore, that this Harmony was ever widely used, or that it exerted any influence on the text of the Gospels, except in Syriac. To the present writer it seems probable that it never did exist in Greek, and that in both forms, Latin and Syriac, it was in origin a missionary substitute for a translation of the complete text of the Canonical Four. The Latin form, the arrangement of which though not the original wording is well preserved in *Fuld*, must have been the earlier: what "Tatian" took back with him to his native land (Epiphanius, *Haer.* xli. 1), where it became "The Gospel" to his converts, was a revised and improved edition.

Acts.—The text of *Acts* is connected with that of the Gospels, but the problem is in some ways different, as (except in the case of the great Bibles, which can hardly have existed in ante-Nicene conditions) the transmission of *Acts* has been separate from that of the Gospels. We have in *Acts* an Alexandrian and a Western text as in the Gospels. The Byzantine text is little more in *Acts* than a modification of the Alexandrian, with a few minor Western readings taken up here and there. But the Western text, as read in D and the Old-Latin texts (very little information in detail about the Old-Syriac of *Acts* survives), differs considerably from the Alexandrian, so much indeed as to have suggested to various scholars, notably Blass, that the Western was the original form and the Alexandrian a "second edition revised and corrected," perhaps by the author himself. The important "West-

TITLE PAGES FROM EARLY BIBLES OF THE ENGLISH REFORMATION

As it came to passe, that
as the people pressed by
our him to heare the word
of God, hee stood by the
lake of Genesareth.

2 And saw two ships standing by the lake: but the fishermen were gone out of them, and were washing their nets.

3 And he entred into one of the ships,
which was Simons, and prayed him,
that hee would thrust out a little from
the land: and he sat down, and taught
the people out of the ship.

4. **Now** when he had left speaking, he said unto Simon, Launch out into the deepe, and let downe your nets for a while.

* **O** my soule magnifyth **o** Lord. And my
heart hath reioyced in God my Saviour. **o**
For he hath looked on the lowe degree of my
haire mayden: for lo: now from hence forth
shall all generations call me blessed. Because
he is in mydder, hath done to me greates
things, & helpe is his name. And his mercie
is on the that feare him, from generation to
generation. he hath shewed strength with
his arme, he hath scattered the that are proud
in the magnificacion of their deite. * he
hath putte downe the mydder from their
seates, and exalted them of lowe degree. he
hath fylled the hungry with good thynges: and
sent a waye the rich emptye. he hath helpe
his seruunt Israel, in remembrance of his
mercie.

B Though prophecies sayle, or tunces
ceasse, or knowlege perishe, yet loue sallerch
neuer awaie. For oure knowlege is vnpar-
fecte, and oure prophesiege is vnparfecte.
But reha that which is perfect, commeth,
then shal the vnparfecte be done awaie.
When I was a childe, I spake as a childe,
I vnderstode as a childe, I imagined as a
childe. But as soone as I was a man, I put
awaie childishnes. Now we se thour a
glasse in a darke speat ynge, but the shal we
se face to face. Now I knowe vnperfectly:
but the shal I knowe eu as I am knowne.
Now abyderth faith, hope, loue, these thie:
11 but the greatest of these is loue.

ern readings" preserved in the Harklean Syriac version are derived from Greek mss. and are not a survival from the lost Old-Syriac (Ropes, ccxvii.). The objections to Blass's theory are to be found in J. H. Ropes, *The Text of Acts* (especially p. ccxxviii. ff.). Ropes regards the Western form as a text rewritten in accordance with the reviser's own literary taste, "which was somewhat different from that of the author" (p. ccxxxi.), and inferior to the original in dignity, force and charm. But here and there, as in the Gospels, this early corrupt recension preserves isolated good readings lost elsewhere, most of which will be found in the marginal variants marked J.H.R. below Prof. Ropes's transcript of codex B. The two most important various readings in Acts are at xv. 29 and at the beginning of the book. In xv. 29 the Western phalanx omits "and from things strangled" from the list of things to be avoided by Gentile Christians, whereby it was possible to interpret the Apostolic Decree as a moral standard (forbidding idolatry, murder and unchastity) rather than as a food-law. Prof. Ropes, though he is inclined to omit *καὶ πνικτῶν* with the Westerns, shows clearly that the Decree must even so have been intended as a food-law: the only doubt that remains, after his careful discussion, is whether *καὶ πνικτῶν* be not original after all. The opening sentence of Acts is best preserved in the African Latin as quoted by Augustine: it points back, according to Ropes, p. 257, to a form like the ordinary text, but without *οὗς* and *ἀνελημφῶν*, so that the true text would run "The former treatise have I made . . . of all that Jesus began . . . what time he gave commands to the apostles by holy Spirit and chose them . . . to whom he showed himself alive, etc."

It is appropriate to notice here that the last chapter of the Gospel of Luke contains in the ordinary text (including B) some eight or nine interpolations omitted by D and the best Old-Latin texts. These are all obviously one series, made at the same time, and they include the reference to the Ascension of Jesus in Luke xxiv. 51^b. It is likely that both these interpolations and the re-writing of Acts i 1 ff. were made at the same time and under the same circumstances, viz., when the two volumes of "*Lucas ad Theophilum*" were separated, the one to form a constituent member of the Canon of Four Gospels, the other to circulate as an independent account of the early days of the Church. In the original undivided work the actual Ascension will only have been chronicled in Acts i. 9-12.

Pauline Epistles.—The *Pauline Epistles* are a collected edition of the Apostle's correspondence, due in the first place (so it seems) to Marcion, and afterwards enlarged by the inclusion of the "Pastoral Epistles" to Timothy and Titus, and of the "Epistle to the Hebrews." Romans, 1 Corinthians and Ephesians seem from the evidence of the "Apostolic Fathers," especially Ignatius and Clement, never to have been forgotten, but the others (notably II. Corinthians and Galatians) seem, at least to the present writer, to have been rescued by Marcion from oblivion.

The words "in Ephesus" in Eph. i. 1 are omitted by κ^* B, by Origen, and apparently by the Old-Syriac (as appears from the Commentary of Ephraim). Marcion called this Epistle "To the Laodiceans." Probably, therefore, it was originally a circular letter, with a blank left for the name in the opening address. This explanation may also be held to account for the diverse forms in which the Epistle to the Romans has been handed down. It is known that Marcion's text wanted chaps. xv. and xvi.; the great doxology at the end (xvi. 25-27) is given after chap. xiv. in most Byzantine documents, many of them repeating it at the end as well, while on the other hand G^{msl} and some other Western texts omit it altogether; further G^{msl} (and apparently also the text underlying D^{msl}) omits all mention of "Rome" in i. 7 and 15. It seems likely, therefore, that "Romans" was an earlier circular letter of St. Paul's, a dogmatic *épître* suitable for any early Christian community that the Apostle had not yet visited, which was turned into a letter to the Roman Church by the addition of chaps. xv. and xvi., when he had made his plan to go there after his final visit to Jerusalem.

It should be noted that Hebrews comes before the Pastoral Epistles in the best Greek tradition; in the Sahidic it comes after II. Corinthians (a rearrangement of the Epistles more or less ac-

cording to length); in the West, before the Vulgate appeared, Hebrews was hardly included at all. Philemon, though in Marcion's collection, comes after Timothy and Titus.

There is little special to say about the text of the *Catholic Epistles* which are usually found bound up with mss. of Acts. The *Apocalypse* has a textual history of its own. Apart from the great Bibles it is generally found separate, or in volumes of miscellaneous content. Sometimes Apocalypse-Acts-Catholic Epistles together form one volume, as in the African Latin *h* (6th century). The true grouping of our authorities in the Apocalypse is still obscure, but for the most part the variants are of minor importance. It may be noted that in xiii. 18 the Number of the Beast, given as 666 in most documents, is 616 in the 5th century uncial C, a curious variant current in the West as early as Irenaeus.

BIBLIOGRAPHY.—B. F. Westcott and F. J. A. Hort, *The New Testament in the Original Greek* (vol. ii. is Hort's *Introduction*) (1881 and 1896). From the very large mass of specialist literature, some of which is named in the preceding paragraphs, the following will be found useful by the student: B. H. Streeter, *The Four Gospels* (London, 1924); J. H. Ropes, *The Text of Acts* (London, 1926); K. Lake and R. P. Blake, *The Text of the Gospels and the Koridethi Codex*, Harvard Theol. Rev. xvi., pp. 267-286 (July, 1923); F. C. Burkitt, *W and O*, J. Theol. Studies, xvii., pp. 1-21, 139-152 (Oct. 1915).

4. HISTORY OF HISTORICAL CRITICISM

The New Testament is a series of early Christian writings which the Church came to regard as canonical, *i.e.*, they were placed in the same category as the Old Testament, the writings which the Christian had inherited from the Jewish Church. Just as the ancient Scriptures were considered to be the Word of God, and therefore that what they contained was the true and inspired doctrine, so also the New Testament was available for proving the Church's dogma. The assured canonicity of the whole New Testament resulted in its use by the mediaeval theologians, the Schoolmen, as a storehouse of proof-texts. Thus the New Testament seemed to exist in order to prove the Church's conclusions, not to tell its own tale.

Erasmus.—The *Novum Instrumentum* published by Erasmus in 1516 (*see above*) was accompanied with a Latin rendering of his own, in which he aimed at giving the meaning of the Greek without blindly following the Latin Vulgate, the only form in which the New Testament had been current in western Europe for centuries. This rendering of Erasmus, together with his annotations and prefaces to the several books, make his editions the first great monument of modern Biblical study. Mediaeval Bibles contain short prefaces with stereotyped information; Erasmus distinguishes, *e.g.*, between the direct statements in the Acts and the inferences which may be drawn from incidental allusions in the Pauline Epistles, or from the statements of ancient non-canonical writers. (For example, from the preface to the Acts: "Dionysius, bishop of the Corinthians, a very ancient writer, quoted by Eusebius, writes that Peter and Paul obtained the crown of martyrdom by the command of Nero on the same day." And again: "Some industrious critics have added [to the narrative of Acts] that Paul was acquitted at his first trial by Nero. . . . This conjecture they make from the 2nd Epistle to Timothy. . . .") This discrimination of sources is the starting point of scientific criticism.

The Reformers.—The champions of Church reform in the beginning of the 16th century found in the Bible their most trustworthy weapon. The New Testament picture of Apostolical Christianity offered indeed a glaring contrast to the papal system of the later middle ages. Moreover, some of the "authorities" used by the Schoolmen had been discovered by the New Learning of the Renaissance to be no authorities at all, such as the writings falsely attributed to Dionysius the Areopagite. When, therefore, the struggle between reformers and conservatives within the undivided Church was transformed into a struggle between Protestants and Romanists, the authority which in previous centuries had been ascribed to the Church was transferred by the Reformed Churches to the Bible. "The Bible, the Bible alone, is the religion of Protestants" did really express the general theory of the anti-Romanist parties. (The phrase is Chillingworth's [1637], who may be described as a Broad High-Churchman.) At the begin-

ning of the movement the New Testament itself had been freely criticized. Luther judged the contents of the New Testament by the light of his leading convictions; and in his German translation, which occupies the same place in Germany as the Authorized Version of 1611 does in English-speaking lands, he even placed four of the books (Hebrews, James, Jude, Apocalypse) in an appendix at the end, with prefaces explanatory of this drastic act of criticism. But Luther's discriminations were in the 17th century ignored in practice.

Influence of Textual Criticism.—From cover to cover the whole New Testament was regarded at the beginning of the 18th century by almost all Protestants as the infallible revelation of the true religion. The doctrines of Christianity, and in many communities the customs of the Church, were held to be inferences from the inspired text of the Scriptures. The first serious blow to this view came from the study of textual criticism. The editions of Mill (1707) and of Wetstein (1751) proved once for all that variations in the text, many of them serious, had existed from the earliest times. It was evident, therefore, that the true authority of the New Testament could not be that of a legal code which is definite in all its parts. More important still was the growing perception of the general uniformity of nature, which had forced itself with increasing insistence upon men's minds as the study of the natural sciences progressed in the 17th and 18th centuries. The miracles of the New Testament, formerly regarded as bulwarks of Christianity, now appeared as difficulties needing explanation. Furthermore, the prevailing philosophies of the 18th century supposed that a real divine revelation would express itself in a form convincing to the reason of the average plain man, whatever his predisposition might be; it was obvious that the New Testament did not wholly conform to this standard.

Rationalists.—But if the New Testament be not itself the direct divine revelation in the sense of the 18th century, the question still remains, how we are to picture the true history of the rise of Christianity, and what its true meaning is. This is the question which has occupied the theologians of the 19th and 20th centuries. Perhaps the most significant event from which to date the modern period is the publication by Lessing in 1774-77 of the "Wolfenbüttel Fragments," i.e., H. S. Reimarus' posthumous attack on Christianity (see A. Schweitzer, *Quest of the Historical Jesus*, pp. 13-26). Lessing's publication also helped to demonstrate the weakness of the older rationalist position, a position which really belongs to the 18th century, though its best-remembered exponent, Dr. H. E. G. Paulus, died only in 1851. The characteristic of the rationalists was the attempt to explain away the New Testament miracles as coincidences or naturally occurring events, while at the same time they held as tenaciously as possible to the accuracy of the letter of the New Testament narratives. The opposite swing of the pendulum appears in D. F. Strauss: in his *Leben Jesu* (1833) he abandons the shifts and expedients by which the rationalists eliminated the miraculous from the Gospel stories, but he abandons also their historical character. According to Strauss the fulfillments of prophecy in the New Testament arise from the Christians' belief that the Christian Messiah must have fulfilled the predictions of the prophets, and the miracles of Jesus in the New Testament either originate in the same way or are purely mythical embodiments of Christian doctrines.

Tübingen School.—The main objection to the presentation both of Strauss and the rationalists, is that it is very largely based not upon the historical data, but upon pre-determined theory. Herein lies the permanent importance of the work of Ferdinand Christian Baur, professor of theology at Tübingen from 1826 to 1860. The corner-stone of his reconstruction of early Christian history was derived not so much from philosophical principles as from a fresh study of the documents. Starting from Galatians and I Corinthians, which are obviously the genuine letters of a Christian leader called Paul to his converts, Baur accepted II. Corinthians and Romans as the work of the same hand. From the study of these contemporary and genuine documents, he elaborated the theory that the earliest Christianity, the Christianity of Jesus and the original apostles, was wholly Judaistic in tone and practice. Paul, converted to belief in Jesus as Messiah after the Crucifixion,

was the first to perceive that for Christians Judaism had ceased to be binding. Between him and the older apostles arose a long and fierce controversy, which was healed only when at last his disciples and the Judaizing disciples of the apostles coalesced into the Catholic Church. This, according to Baur, happened early in the 2nd century, when the strife was finally allayed and forgotten. The various documents which make up the New Testament were to be dated mainly by their relation to the great dispute. The Apocalypse was a genuine work of John the son of Zebedee, one of the leaders of the Judaistic party, but most of the books were late, at least in their present form. The Acts, Baur thought, were written about A.D. 140, after the memory of the great controversy had almost passed away. All four Gospels also were to be placed in the 2nd century, though that according to Matthew retained many features unaltered from the Judaistic original upon which it was based.

Later Views.—The Tübingen school founded by Baur dominated the theological criticism of the New Testament during a great part of the 19th century. Baur's main position was not so much erroneous as one-sided. The quarrel between St. Paul and his opponents did not last so long as Baur supposed, and the great catastrophe of the fall of Jerusalem effectually reduced thoroughgoing Judaistic Christianity into insignificance from A.D. 70 onwards. Moreover, St. Paul's converts do not seem to have adopted consistent "Paulinism" as a religious philosophy. St. Paul was an emancipated Jew, but his converts were mostly Greeks, and the permanent significance of St. Paul's theories of law and faith only began to be perceived after his letters had been collected together and had been received into the Church's canon. All these considerations tend to make the late dates proposed by Baur for the greater part of the New Testament books unnecessary; modern investigators, notably Harnack of Berlin, accept dates not far removed from the ancient Christian literary tradition.

Literary criticism of the Gospels points to a similar conclusion. A hundred years' study of the synoptic problem, i.e., the causes which make the Gospels according to Matthew, Mark and Luke at once so much alike and so different, has resulted in the demonstration of the priority of Mark, which "was known to Matthew and Luke in the same state and with the same contents as we have it now." (J. Wellhausen, *Einkl. in die drei ersten Evangelien*, p. 57 [1905]). This Gospel may be dated just before A.D. 70. Luke and Matthew appear to have been published between 80 and 100. If Luke used Josephus, as F. C. Burkitt and others believe, the later date must be taken; but in any case it should be within the lifetime of a companion of St. Paul. Besides the Gospel of Mark these Evangelists made use of another document, now lost, which contained many sayings of Jesus and some narratives not found in Mark. This document was by many scholars identified with the "Logia," mentioned by Papias (Eusebius, *Ch. Hist.* iii. 39) as being the work of Matthew the Apostle, but the identification is not certain, and since Wellhausen it has been commonly dubbed Q (for *Quelle* "Source").

The Johannine writings, i.e., the Fourth Gospel and the three Epistles of John, represent the view of Christ and Christianity taken by a Christian teacher, who seems to have lived and written in Asia Minor at the close of the 1st century A.D. The value of the Fourth Gospel as a narrative of events is a matter of dispute, but the view of the personality of Jesus Christ set forth in it is unquestionably that which the Church has accepted.

The discoveries of papyri in Upper Egypt during recent years, containing original letters written by persons of various classes and in some cases contemporary with the Epistles of the New Testament, have immensely increased our knowledge of the Greek of the period, and have cleared up not a few difficulties of language and expression. More important still is the application of Semitic study to elucidate the Gospels. It is idle indeed to rewrite the Gospel narratives in the Aramaic dialect spoken by Christ and the apostles, but the main watchwords of the Gospel theology—phrases like "the Kingdom of God," "the World to come," the "Father in Heaven," "the Son of Man,"—can be more or less surely reconstructed from Jewish writings, and their meaning gauged apart from the significance which they received in

Christian hands. This line of investigation has been specially followed by G. Dalman in his *Worte Jesu*.

BIBLIOGRAPHY.—See the separate bibliographies to the separate articles on the books of the New Testament. The selection here given of the vast literature of the subject has been drawn up with the idea of setting the student on his way. 1. General and Historical.—Jerome's *Prefaces* (to be found in any R.C. edition of the Vulgate); Luther's *Prefaces* (to be found in German-printed editions of Luther's Bible); F. Seeböhm, *The Oxford Reformers* (3rd ed., London, 1887)—for Erasmus; M. Creighton, "Chillingworth" in the *Dict. of Nat. Biogr.*; Chr. Schrempf, *Lessing als Philosoph* (Stuttgart, 1906); J. Estlin Carpenter, *The Bible in the 19th century* (London, 1903); A. Schweitzer, *Von Reimarus zu Wrede* (Tübingen, 1906): see next section. 2. For the Synoptic Gospels.—W. G. Rushbrooke, *Synopticon* (London, 1880); Sir J. C. Hawkins, *Horae Synopticae* (Oxford, 1899; 2nd ed., 1909); Julius Wellhausen, *Entstehung in die drei ersten Evangelien* (Berlin, 1905; 2nd ed., 1911); *Das Evangelium Marci* (1903; 2nd ed., 1909); *Das Ev. Matthaei* (1904), *Das Ev. Lucae* (1904)—these four books make one work. 3. For the Fourth Gospel.—K. G. Bretschneider, *Probabilia* (Leipzig, 1820); Matthew Arnold's *God and the Bible*, chaps. v., vi. (still the best defence in English of a Johannine kernel, new ed. 1884); W. Sanday, *Criticism of the Fourth Gospel* (Oxford, 1905); A. Loisy, *Le Quatrième Évangile* (Paris, 1903); P. W. Schmiedel, *Das vierte Evangelium gegenüber den drei ersten* (Halle, 1906). 4. For the Semitic Elements in the N.T.—G. Dalman, *Die Worte Jesu* (Leipzig, 1898) (Eng. trans. *The Words of Jesus*, 1905); Johannes Weiss, *Die Predigt Jesu vom Reiche Gottes* (1st ed., 1892, 2nd ed., 1900). The Protestant view of the New Testament in A. Harnack, *Das Wesen des Christentums* (Berlin, 1900) (Eng. trans. *What is Christianity?* London, 1901) may be compared with the Liberal Catholic view in A. Loisy, *L'Évangile et l'Église* (2nd. ed., 1903).

5. MODERN CRITICISM

Modern critical work on the New Testament is so enormous in bulk that all that can be noticed here is a small selection of things which seem to the present writer particularly characteristic and significant. The subjects treated of may be grouped under three heads: Eschatology, Attempts to Reconstruct "Q," and the Historicity of Mark.

Eschatology.—Belief in a second advent of Christ has always been an article of the official creed of Christendom. It has further been commonly held that the New Testament contains indications of the signs of the approaching End, and from time to time enthusiasts have identified the approaching End with their own time or that immediately ahead. Nevertheless the End has not arrived; and indeed even if it did come now it would not be a real fulfilment of what is written in the New Testament, for what is expected there is a *then* immediate End. In II. Peter iii. 8 *seq.*, the "Day of the Lord" is extended to a period of 1,000 years, but experience has long shown that even that does not suffice. Moreover, the advance of knowledge in modern times about the configuration of the universe has demonstrated that the whole picture of the expected consummation is inconceivable if taken literally.

For a long time, therefore, the tendency of "enlightened" scholarship was to ignore or to explain away the clearly eschatological passages of the New Testament, or else to make distinctions between the "spiritual" ideas of Jesus and the "materialistic superstition" of the early disciples. Much effort was expended in the attempt to make the message and teaching of Jesus into something like the "liberal" ideas of religion current in the 19th century. The history of this attempt and its failure is brilliantly written in Albert Schweitzer's *Von Reimarus zu Wrede* (1906), called in the English translation "The Quest of the Historical Jesus" (1910).

The effect of Schweitzer's book has been very marked, and it is generally now acknowledged that the New Testament is a collection of writings by persons who, much as they differed in other things were agreed in this, that they lived in a world that was rapidly coming to an end, a world in which men and women might indeed rear children, but no one could look forward to a next generation. The effective reason for not taking thought for the morrow was the improbability that to-morrow would ever arrive. Hence the discouragement of marriage, the little care for the training of children, and the absence of public spirit and interest in the affairs of the world, manifested in the New Testament. It should be added that, although the writer of I John ii. 18

declares it was then "the last hour," it is in the Johannine writings that we see the beginnings of a tendency to reinterpret the earlier Christian expectations of an immediate conclusion of world-history.

A further development, which has gone side by side with the full recognition of the fact that Jesus and His disciples were expecting the near approaching End, is a more thorough study of Jewish popular beliefs in the age between that of the Maccabees (from 168 B.C.) and that of the 1st century A.D. It was no special superstition of the Christians, but the general expectation of the Jewish people that "the Kingdom of God was immediately to appear" (Luke xix. 11). This belief sent them to war with Rome in A.D. 66, a war which ended with the extinction of the Jewish state and the destruction of Jerusalem in A.D. 70. The belief had been engendered by two centuries of peculiar history, and it is only just to Jews and Christians alike to remember that this belief was the form in which they expressed faith in God's providential government of the world and in the ultimate triumph of justice. These ideas are best studied in the series of Jewish Apocalypses—Enoch, Assumption of Moses, Baruch, "Second Esdras" (= 4 Ezra)—which have all received their due measure of attention in the last 20 years.

Attempts to Reconstruct "Q."—That Matthew and Luke made use of Mark is now generally recognized. Besides Mark they must also have used another document, now generally spoken of as Q, which formed the basis of their accounts of John the Baptist, the Temptation of Jesus, the "Sermon on the Mount" (*i.e.*, a collection of Sayings beginning with Beatitudes and ending with the simile of the Two Houses), the Story of the Centurion's Boy, Sayings of Jesus about John, some Parables, some Sayings about the End. Many efforts, notably Harnack's, have been made to reconstruct Q in detail, but all that is really assured about it is contained in the above description. We do not know what it did *not* contain, and we do not know its more striking peculiarities (which neither Matthew nor Luke saw fit to incorporate). It is therefore hazardous to estimate its historical and theological tendencies as a whole, *e.g.*, as compared with Mark, a document actually before us. Moreover, Matthew and Luke each contains single Sayings and Parables which it is difficult not to regard as genuine reminiscences of Jesus, and yet there is no literary reason to suppose that they came from Q, *e.g.*, Luke xi. 5-8, xviii. 1-14; Matt. xiii. 44-52, xx. 1-16. Each of the three synoptic Gospels, therefore, contains an element which must not be neglected: it is simply unscientific to regard Sayings of Jesus labelled "Q" as authentic and those not so labelled as unauthentic.

Nevertheless the arguments which establish the fact of Q remain, and an attractive attempt to restate the problem has been made in B. H. Streeter's *The Four Gospels* (1924). Streeter believes in the fact of Q (his reconstruction is to be found on p. 291 of his book); as used by Matthew and Luke it was a Greek document, current probably at Antioch. But both Matthew and Luke had a special source. In the case of Matthew it seems to come from the tradition of the Christians of Jerusalem (Matt. xxvii. 8, xxviii. 15), mere legend so far as narrative is concerned, but preserving genuine Sayings of Jesus. These legends and Sayings, together with "Q," the Evangelist has worked into his main source, which is Mark, so that the Gospel of Matthew may be described as a "second edition of Mark, revised and enlarged." The place of writing was almost certainly Antioch, and the point of view is not that of the conservative Church of Jerusalem which had James for its leader, but the more liberal and catholicizing Church of Antioch which looked to Peter (Matt. xvi. 18 *seq.*: Streeter, p. 515). Streeter's view of the sources of Luke is more complicated. He sees that the Gospel of Luke is not so much a narrative based on Mark as one into which detached blocks of Mark have been inserted. He supposes, therefore, that the Evangelist had drawn up a narrative based on Q and his own researches, possibly conducted when a companion of St. Paul during his two years' imprisonment at Caesarea (Acts xxiv. 27); this may be represented graphically as Q+L, and is called by Streeter "Proto-Luke." Some years later Luke came across the Gospel of Mark: he saw its value and published a second edition of his former

work, incorporating long sections of Mark into it and at the same time prefixing his story of the Infancy of Jesus. (This is inferred from Luke iii. 1, "surely . . . written as the opening section of a book," p. 209.)

The attraction of this ingenious theory lies in its historical possibility, its explanation of the actual literary phenomena of the Third Gospel and also of the large amount of fresh matter there found, for on this hypothesis the peculiar matter of Luke is the tradition of Caesarea, a distinct centre of the earliest Christianity. But if accepted it shows all the more clearly how little we know of the public career of Jesus, apart from the narrative of Mark. The present writer has compiled a *précis* of the career of Jesus drawn from Luke alone in *Beginnings of Christianity*, vol. ii., p. 486: any one who reads that *précis* or makes a similar one for himself will see the total inadequacy of this framework, and if we withdraw from it the details supplied by Mark it comes to no more than that Jesus first preached in Galilee and then proceeded to Jerusalem. Of the course of His ministry or the train of circumstances that led up to His visit to Jerusalem there is no intelligible picture in "Proto-Luke." (A line of investigation might be pursued, enquiring whether the evidence does not suggest that Q, as known to Luke and Matthew, was itself composite, viz., a set of Sayings, originally in Aramaic, and a Greek set dealing particularly with John the Baptist and his relation to Jesus. It is in sections about John the Baptist that verbal coincidences between Matthew and Luke chiefly occur.)

The Historicity of Mark.—The whole tendency of modern critical investigation has been to emphasize the priority of the Gospel of Mark. The old conception that from earliest times there had been a coherent oral tradition of the career of Jesus, of which the written Gospels are slightly individual embodiments, has dissolved. Investigation into the written Gospels has revealed glimpses of earlier documents such as Q or "Proto-Luke," but they are not "Lives" of Jesus in the sense that Mark is a Life of Jesus. As far as we can see it was the writer of "Mark" who turned the Gospel into a Biography. That, in fact, was his great achievement. But in proportion as Mark is regarded as the unique source for the Biography the question of its historical value becomes acute.

History is not a deductive science and there are no generally recognized rules for detecting fact. There are rules for detecting fiction, but that is a different thing altogether. It is not surprising, therefore, that very different views of the value of Mark as an historical document have been put forward in recent times.

There are a few writers who disbelieve altogether in the existence of Jesus as an historical personage, who regard Jesus as a dogma personified. For most people it will suffice to say of this theory with C. G. Montefiore: "Without Jesus, no Mark" (*The Synoptic Gospels*, i. 169). But a good answer at length and from a rationalistic standpoint is to be found in *The Historical Christ*, by F. C. Conybeare (London, 1914). More important is the scepticism about all details exhibited by Loisy in France and by Bultmann in Germany. Prof. R. Bultmann of Marburg is one of the most influential of the younger theologians in Germany; his literary analysis of the sources is to be found in his *History of the Synoptic Tradition* (1921) and his view of the Gospel Sayings in his "Jesus" (1926). In Bultmann's opinion the Sayings are all that is historical: the tales of Jesus, together with the general framework of the Gospel History, he regards as a product of the missionary needs of early Hellenistic Christianity. Jesus was an eschatological prophet, a herald of the coming kingdom or rule of God: no doubt He was crucified and believed by disciples to have been alive again, but that is all we know about Him for certain, according to Bultmann.

The discussion of this radical scepticism belongs to another department of study: it is given prominence here, because it is a characteristic result of the literary criticism of the Gospels, which has ended in tracing the authority for the Gospel narrative to the work of Mark. The present writer is very far from sharing Bultmann's views. When the theological beliefs of the early Christians are considered, their belief in the Lord Jesus over

whom death had no power, who was now sitting in heaven at God's right hand and was shortly to come again to judge all mankind, living and dead, it seems difficult to believe that an account of the career of Jesus like that in Mark can be due to anything but somebody's reminiscences, or at least that somebody's reminiscences are an important constituent part of it. Not only the poignant scene in Gethsemane and the cry of despair from the Cross, but many minor touches, such as the tame ending to the Entry into Jerusalem (Mark xi. 11), or the boat that waited on Jesus because of the crowd (Mark iii. 9), betray the eyewitness. What should we think of these things if they had recently for the first time been disinterred from a newly-discovered papyrus?

What is really valuable and edifying in Bultmann's historical scepticism—and the same may be said of Loisy—is that it points out real historical difficulties in the Gospel History, real inconsequences which require a sound historical view if the whole narrative is not to fall to pieces. It may be said with little exaggeration that scholars regard Mark as serious history according as they take Mark vii. 31 to be historical or not, i.e., according as they think it probable that a whole summer and autumn were spent by Jesus practically in retirement outside the land of Israel (see K. L. Schmidt, *Rahmen*, p. 200, note). It is not only the "miracles" which require explanation, it is the whole historical situation, and if we have a false idea of that situation or no idea at all, as is more often the case, the tale becomes incoherent and we ask, with Bultmann and Loisy, why we are expected to believe it. "At the same time, the more we study the special aims and tendencies of the Synoptic Evangelists, the greater the gap appears between the theories which they themselves elaborate and the circle of ideas in which the Sayings of Jesus move. Again and again we find ourselves in the presence of something which may or may not be authentic historical reminiscence, but is in any case totally unlike the other remains of early Christian literature. We cannot tell whether the tale be well remembered, or how many steps there may have been in its transmission, but the difference of spirit is unmistakable, and we take knowledge of the Evangelists that they have been with Jesus" (quoted by Montefiore, *The Synoptic Gospels*, vol. i., p. 82).

6. CHRONOLOGY

The subject of the chronology of the New Testament falls naturally into two distinct sections: the chronology of the Gospels, that is, of the life of Christ; and the chronology of the Acts, that is, of the apostolic age.

The Chronology of the Gospels.—The data group themselves round three definite points and the intervals between them: the definite points are the Nativity, the Baptism and the Crucifixion; the age of Christ at the time of the Baptism connects the first two points, and the duration of his public ministry connects the second and third. The results obtained under the different heads serve mutually to test, and thereby to correct or confirm, one another.

1. The date of the Nativity as fixed according to our common computation of Anno Domini (first put forward by Dionysius Exiguus at Rome early in the 6th century) has long been recognized to be too late. The fathers of the primitive church had been nearer the truth with the years 3 or 2 B.C. (see Irenaeus, *Haer.* III. xxi. 3 [xxiv. 2]; Clement of Alexandria, *Strom.* i. 21, p. 147; Hippolytus, in *Dan.* iv. ed. Bonwetsch, p. 242; [Tertullian], *adv. Jud.* 8). What may be called the received chronology during the last two centuries has pushed the date farther back to 4 B.C. But the considerations now to be adduced make it probable that the true date is earlier still.

(a) *Evidence of St. Matthew's Gospel* (i. 18-ii. 22).—The birth of Christ took place before the death of Herod, and the evidence of Josephus fixes the death of Herod with some approach to certainty. His various calculations are not indeed quite easy to harmonize, but the extent of choice for the year of Herod's death is limited to the years 4 and 3 B.C., with a very great preponderance of probability in favour of the former. How long before this the Nativity should be placed the Gospel does not enable us to say precisely.

(b) *Evidence of St. Luke's Gospel* (ii. 1-8).—The birth of Christ took place at the time of a general census of the empire ordered by Augustus: "it was the first census, and was made at the time when Quirinius was governor of Syria." Against this account it has been urged that we know that the governorship of Syria from 10 or 9 B.C. down to and after Herod's death was held successively by M. Titius, C. Sentius Saturninus, and P. Quintilius Varus; and further, that when Judaea became a Roman province on the deposition of Archelaus in A.D. 6, Quirinius was governor of Syria, and did carry out an elaborate census. The notice in the Gospel, it is suggested, grew out of a confused recollection of this later operation. But the confusion in question would only be likely, if there really was a census at the time of the Nativity; and it is no more improbable that Herod should have held, or permitted to be held, a local census than that Archelaus of Cappadocia in the reign of Tiberius (Tacitus, *Ann.* vi. 41) should have taken a census of his own native state "after the Roman manner." At the same time St. Luke's account, when the name of Quirinius is subtracted from it, ceases to contain any chronological evidence.

(c) *Evidence of Tertullian*.—Strangely enough, however, the missing name of the governor under whom the census of the Nativity was carried out appears to be supplied by a much later writer. Tertullian, in fact (*adv. Marc.* iv. 19), argues against Marcion that it was well known that Sentius Saturninus carried out a census under Augustus in Judaea, by consulting which the family and relationships of Christ could have been discovered. This Saturninus was the middle one of the three governors of Syria named above, and as his successor Varus must have arrived by the middle of 6 B.C. at latest (for coins of Varus are extant of the 25th year of the era of Actium), his own tenure must have fallen about 8 and 7 B.C., and his census cannot be placed later than 7 or 7-6 B.C. The independence of Tertullian's information about this census is guaranteed by the mere fact of his knowledge of the governor's name; and if there was a census about that date, it would be unreasonable not to identify it with St. Luke's census of the Nativity.

The traditional Western day for the Christmas festival, Dec 25, goes back as far as Hippolytus, *loc. cit.*; the traditional Eastern day, Jan. 6, as far as the Basilidian Gnostics (but in their case only as a celebration of the Baptism), mentioned by Clement of Alexandria, *loc. cit.*

2. The interval between the Nativity and the Baptism.

Evidence of St. Luke's Gospel (iii. 23).—At the time of his baptism Jesus was ἀρχόμενος ὥσπερ ἔτων τριάκοντα. But (i.) ἀρχόμενος does not mean (as Valentinian interpreters thought, *Iren.* ii. xxii. 5 [xxxiii. 3]; so also Epiphanius, *Haer.* li. 16) "beginning to be 30 years" in the sense of "not yet quite 30," but "at the beginning of His ministry," as in Luke xxiii. 5; Acts i. 22, x. 37; (ii.) ὥσπερ ἔτων τριάκοντα does not mean "on attaining the full age of 30, before which he could not have publicly taught," for if there was by Jewish custom or tradition any

minimum age for a teacher, it was not 30, but 40 (*Bab. Talm.* ed. 1715, fol. 19 b; *Iren. loc. cit.*). St. Luke's phrase is a general one, "about 30 years old."

3. The date of the Baptism.

(a) *Evidence of St. Luke's Gospel* (iii. 1).—A *terminus a quo* for the Baptism is the synchronism of the commencement of the Baptist's public ministry with the 15th year of the rule (ἡγεμονία) of Tiberius. Augustus died on Aug. 19. A.D. 14, and, reckoned from that point, Tiberius's 15th year might be, according to different methods of calculation, either A.D. 28, or 28-29 or 29. But any such result would be difficult to reconcile with the results yielded by other lines of investigation in this article; among alternative views the choice seems to lie between the following:—(i.) The years of Tiberius are here reckoned from some earlier starting-point than the death of his predecessor—perhaps from the grant to him of co-ordinate authority with Augustus over the provinces made in A.D. 11 (see, for the parallel with the case of Vespasian and Titus, Ramsay, *St. Paul the Roman Traveller*, p. 387), so that the 15th year would be roughly A.D. 25; or (ii.) St. Luke has made here a second error in chronology, caused perhaps in this case by reckoning back from the Crucifixion, and only allowing one year to the ministry of Christ.

(b) *Evidence of St. John's Gospel* (ii. 13, 20).—A *terminus ad quem* for the Baptism is the synchronism of the first Passover mentioned after it with the 46th year of the building of Herod's Temple. Herod began the Temple in the 18th year of his reign, probably 20-19 B.C., and the Passover of the 46th year is probably that of A.D. 27. This year suits so well with our other data that, while too much stress must not be laid on it, it is not unreasonable to regard it as one of those curiously accurate details that the Fourth Gospel has preserved.

On the whole, then, the Baptism of Christ may be placed in A.D. 26-27; and as the Nativity was placed in 7-6 B.C. (at latest), this would make the age of Christ at his Baptism to be about 32, which tallies well enough with St. Luke's general estimate.

4. The interval between the Baptism and the Crucifixion, or, in other words, the duration of the public ministry of Christ.

(a) *Evidence of St. Mark's Gospel* (ii. 23, vi. 39, xiv. 1).—If the order of events in St. Mark is roughly chronological (as certainly appears to be the case), then Christ's ministry lasted at least two years, since the plucking of the ears of corn (April-June) marks a first spring; the feeding of the 5,000 when the grass was fresh green (χλωρός: about March), a second; and the Passover of the Crucifixion a third.

(b) *Evidence of St. Luke's Gospel* (ix. 51-xix. 28 compared with iv. 14-ix. 50; iv. 19).—An impression of a briefer ministry is, however, suggested by St. Luke. The second and larger half of the narrative of the ministry is introduced at ix. 51 with the words, "It came to pass as the days of His assumption were coming to the full, He set His face firmly to go to Jerusalem," under which phrase the evangelist cannot have meant to include more than a few months at most; so that even if the earlier and shorter half of the account, which describes a purely Galilean ministry is to be spread over a longer period of time, the combined narrative can hardly have been planned on the scale of more than a single year. St. Luke himself may have understood literally, like so many of his readers in ancient times, the reference which he records to the "acceptable year of the Lord" (iv. 19= Isaiah lxi. 2): see, too, above 3 (a) *ad fin.*

(c) *Evidence of St. John's Gospel* (ii. 13, "the Passover of the Jews was near," and 23, "He was in Jerusalem at the Passover at the feast"; v. 1, "After these things was a feast [or 'the feast'] of the Jews"; vi. 4, "and the Passover, the feast of the Jews, was near"; vii. 2, "and the feast of the Jews, the Tabernacles, was near"; x. 22, "at that time the feast of dedication took place at Jerusalem"; xi. 55, "and the Passover of the Jews was near"; besides iv. 35, "say ye not that there is yet a period of four months and harvest cometh? Behold, I tell you, lift up your eyes and see the fields that they are white to harvest"). This catena of time-references is of course unique in the Gospels as a basis for a chronology of the ministry; and it is not reasonable to doubt that the evangelist intended these notices as definite historical data,

possibly with the express purpose of correcting current but erroneous impressions. Whatever difficulties either of reading or of interpretation have been raised in regard to one or other of these notices, the general conclusion that the fourth evangelist drew up his narrative on the basis of a two years' rather than a one year's ministry appears to be irrefragable.

Not only do the Fourth and Second Gospels thus agree in indications of a two years' ministry, but the notes of the middle spring of the three (John vi. 4; Mark vi. 39) both belong to the feeding of the 5,000, one of the most striking points of actual contact between the two Gospels. And in questions of this sort the evidence of Mark and John quite decisively outweighs the evidence of writers so far less precise in detail as Matthew and Luke.

The question, however, may still be raised, whether these time-indications of the two Gospels are exhaustive, whether (that is) two years, and two years only, are to be allotted to the ministry. Irenaeus (ii. xxii. 3-6 [xxxiii. 1-4]), in favour of a ministry of not less than ten years, appeals (i.) to the tradition of Asia Minor; (ii.) to the record in St. John that Christ, who was 30 years old at the time of His Baptism, was addressed by the Jews as "not yet (*i.e.* nearly) 50 years old": but both his arguments are probably derived from a single source, Papias's interpretation of John viii. 57. With this exception, however, all ancient writers, whether they enumerated two or three or four Passovers in the Gospel history, believed that the enumeration was exhaustive; and their belief appears correctly to represent the mind of the author of the Fourth Gospel. Moreover, the wide currency in early times of the tradition of the single-year ministry (Ptolemaeus *ap. Iren. loc. cit.*; *Clem. Hom.*, xvii. 19; *Clem. Alex. Strom.* i. 145, vi. 279; Julius Africanus, *ap. Routh, Rel. Sacr.* ii. 240, 306; Hippolytus, *Paschal Cycle and Chron.*; Origen, *in Levit. Hom.* ix. 5, *de Princ.*, iv. 5) becomes perhaps more difficult to account for, the farther it is removed from the actual facts.

5 The date of the Crucifixion.

(a) *The Roman Governor.*—Pontius Pilate was on his way back to Rome, after ten years of office, when Tiberius died on March 16, A.D. 37 (Josephus, *Ant.* xviii. ii. 2, iv. 2). For the Crucifixion "under Pontius Pilate" the Passover of A.D. 28 is therefore the earliest possible and the Passover of A.D. 36 the latest. Further, Luke xiii. 1, xxiii. 12, show that he was not quite a newcomer at the time of the Crucifixion.

(b) *The Jewish High-Priest.*—Caiaphas was appointed before Pilate's arrival, and was deposed at a Passover apparently not later than that of the year of Herod Philip's death, A.D. 34 (Josephus, *Ant.* xviii. ii. 2, iv. 3-v. 3). The Crucifixion at some previous Passover would then fall not later than the year A.D. 33.

(c) *The Day of the Week.*—The Resurrection on "the first day of the week" (Sunday) was "on the third day" after the Crucifixion; and that "the third day" implies an interval of only two days hardly needed to be shown, but has been shown to demonstration in Field's *Notes on the Translation of the New Testament* (on Matt. xvi. 21). The Crucifixion was therefore on a Friday in some year between A.D. 28 and 33 inclusive.

(d) *The Day of the Jewish Month Nisan.*—The Passover was kept at the full moon of the lunar month of Nisan, the first of the Jewish ecclesiastical year; the Paschal lambs were slain on the afternoon of the 14th Nisan, and the Passover was eaten after sunset the same day—which, however, as the Jewish day began at sunset, was by their reckoning the early hours of the 15th Nisan; the first fruits (of the barley harvest) were solemnly offered on the 16th. The synoptic Gospels appear to place the Crucifixion on the 15th, since they speak of the Last Supper as a Passover;¹ St John's Gospel, on the other hand (xiii. 1, 29, xviii. 28), distinctly implies that the feast had not yet taken place, and thus makes the Crucifixion fall on the 14th. Early

¹ If the Passover celebration could be anticipated by one day in a private Jewish family (and we know perhaps too little of Jewish rules in the time of Christ to be able to exclude this possibility), the evidence of the synoptic Gospels would no longer conflict with that of St. John. In any case Christians in the Apostolic Age can hardly have kept the evening of the anniversary of the Crucifixion as a feast.

Christian tradition is unanimous on this side; either the 14th is mentioned, or the Crucifixion is made the antitype of the slaughter of the Paschal Lamb (and the Resurrection of the first fruits), in the following authorities anterior to A.D. 235: St. Paul, I. Cor. v. 7, xv. 20; Quartodecimans of Asia Minor, who observed the Christian Pascha on the "14th," no matter on what day of the week it fell; Claudius Apollinaris, Clement of Alexandria, Hippolytus, all three quoted in the *Paschal Chronicle*; Irenaeus (apparently) iv. x. 1 [xx. 1]; [Tertullian] *adv. Jud.*, 8; Africanus, in Routh, *Rel. Sacr.* ii. 297. The Crucifixion, then, should be placed rather on the 14th than on the 15th of Nisan.

These four lines of inquiry have shown that the Crucifixion fell on Friday, Nisan 14 (rather than 15), in one of the six years 28-33 A.D.; and therefore, if it is possible to discover (i.) exactly which moon or month was reckoned each year as the moon or month of Nisan, and (ii.) exactly on what day that particular moon or month was reckoned as beginning, it will, of course, be possible to tell in which of these years Nisan 14 fell on a Friday. To neither question can an answer be given in terms so precise as to exclude some latitude, but to both with sufficient exactness to rule out at once three of the six years. (i.) The difficulty with regard to the month is to know how the commencement of the Jewish year was fixed—in what years an extra month was intercalated before Nisan. If the Paschal full moon was, as in later Christian times, the first after the spring equinox, the difficulty would be reduced to the question on what day the equinox was reckoned. If, on the other hand, it was, as in ancient Jewish times, the first after the earliest ears of the barley harvest would be ripe, it would have varied with the forwardness or backwardness of the season from year to year. (ii.) The difficulty with regard to the day is, quite similarly, to know what precise relation the first day of the Jewish month bore to the astronomical new moon. In later Christian times the Paschal month was calculated from the astronomical new moon; in earlier Jewish times all months were reckoned to begin at the first sunset when the new moon was visible, which in the most favourable circumstances would be some hours, and in the most unfavourable three days, later than the astronomical new moon.

Jewish traditions represented the Sanhedrin as retaining to the end its plenary power over the calendar, and as still fixing the first day of every month and the first month of every year. But as it is quite inconceivable that the Jews of the Dispersion should not have known beforehand at what full moon they were to present themselves at Jerusalem for the Passover, it must be assumed as true in fact, whether or no it was true in theory, that the old empirical methods must have been qualified, at least partially, by permanent, that is in effect by astronomical, rules. The beginning of the Jewish year according to the state of the harvest must have been supplanted by some more fixed relation to the solar year, that is, presumably according to the date of the spring equinox. But if so, the equinox itself must have been put earlier than the Christian reckoning of the 3rd century put it, since Christian controversialists from Anatolius of Laodicea (A.D. 277) onwards accused the Jews of disregarding the equinoctial limit, and of sometimes placing the Paschal full moon before it. Therefore we must allow for the possibility that in the time of Christ the 14th of Nisan might have fallen as far back as, say, March 17. In the following table the first column gives the *terminus paschalis*, or 14th of the Paschal moon, according to the Christian calendar; the second gives the 14th, reckoned from the time of the astronomical new moon of Nisan; the third the 14th, reckoned from the probable first appearance of the new moon at sunset. Alternative moons are given for A.D. 29, according as the full moon falling about March 18 is or is not reckoned the proper Paschal moon.

A.D. 28	Sat. Mar. 27	Mar. 28	Mar. 30
" 29	Th. Mar. 17	Mar. 17	Mar. 19
	F. Apr. 15	Apr. 16	Apr. 18
" 30	Tu. Apr. 4	Apr. 5	Apr. 7
" 31	Sat. Mar. 24	Mar. 25	Mar. 27
" 32	Sat. Apr. 12	Apr. 12	Apr. 14
" 33	W. Apr. 1	Apr. 1-2	Apr. 3 or 4

It will be seen at once that Friday cannot have fallen on Nisan 14th in any of the three years A.D. 28, 31 and 32. The choice is narrowed down to A.D. 29, Friday, March 18 (Friday, April 15 would no doubt be too early even for the 14th of Nisan); A.D. 30, Friday, April 7; and A.D. 33, Friday, April 3.

(e) *The Civil Year* (consuls, or regnal years of Tiberius) in early Christian tradition. It is not *a priori* improbable that the year of the central event from which the Christian Church dated her own existence should have been noted in the apostolic age and handed down to the memory of succeeding generations; and the evidence does go a little way to suggest that we have in favour of A.D. 29, the consulate of the two Gemini, a body of tradition not derived from the Gospels.

The consulship of the two Gemini is given by Lactantius, *Div. Inst.* IV. x. 18, and (Lactantius?) *de morte pers.* § 2; the consulship of the two Gemini=Tiberius 18 by Hippolytus, *Comm. in Daniele*, iv. (ed. Bonwetsch, p. 242); the consulship of the two Gemini=Tiberius 15 by [Tertullian] *adv. Judaeos*, 8; the consulship of the two Gemini=Tiberius 15 (*al.* 18 or 19)=Ol 202.4 (this last is a later interpolation from Eusebius) in the *Acts of Pilate*. Other methods of expressing the year 29 appear in Hippolytus's *Paschal Cycle and Chronicle*, and in the Abgar legend (*ap.* Eusebius, *H.E.* i. 13). Tiberius 15 is given by Clem. Alex. *Strom.* i. 147; Origen, *Hom. in Jerem.* xiv. 13, *cf. c. Cels.* iv. 22; Tiberius 16 by Julius Africanus (Routh, *Rel. Sacr.* ii. 301-304), and pseudo-Cyprian *de pascha computus* (A.D. 243), 20. The date by the consuls has an independent look about it; it was apparently well established by about A.D. 200, and it is just possible that it had been handed down in early Christian circles independently of the Gospels.

(f) *The Civil Month and Day*—The earliest known calculations, by Basilidian Gnostics, quoted in Clem. Alex. *Strom.* i. 147, gave alternative dates, Phamenoth 25, Pharmuthi 25, Pharmuthi 19, that is, according to the fixed Alexandrian calendar of 26 B.C., March 21, April 20, April 14. But to look for genuine traditions among Egyptian Gnostics, or even in the church of Alexandria, would be to misread the history of Christianity in the 2nd century. Such traditions must be found, if anywhere, in Palestine and Syria, in Asia Minor, in Rome, not in Egypt; within the Church, not among the Gnostics. The date which makes the most obvious claim to satisfy these conditions would be March 25, as given by Hippolytus, (*Tert.*) *adv. Judaeos*, and the *Acts of Pilate* (according to all extant mss. and versions, but see below), *loc. cit.*—the same three authorities who bear the earliest witness for the consuls of the year of the Crucifixion—and by many later writers. It cannot be correct, since no full moon occurs near it in any of the possible years; yet it must be very early, too early to be explained with Dr Salmon (*Dictionary of Christian Biography*, iii. 92b), as originated by Hippolytus's Paschal cycle of A.D. 221. Now Epiphanius (*Haer.* i. 1) had seen copies of the *Acts of Pilate* in which the day given was not March 25, but *a.d. xv kal. Apr.* (= March 18); and if this was the primitive form of the tradition, it is easy to see how March 25 could have grown out of it, since the 18th from comparatively early times, in the East at any rate, would have been thought impossible as falling before the equinox, and no substitution would be so natural as that of the day week, March 25. But March 18, A.D. 29 was one of the three alternative dates for the Crucifixion which on astronomical and calendar grounds were found (see above, 5d) to be possible.

Thus A.D. 29 is the year, March 18 is the day, to which Christian tradition (whatever value, whether much or little, be ascribed to it) appears to point. Further, the Baptism was tentatively placed in A.D. 26-27; the length of the ministry was fixed, with some approach to certainty, at between two and three years, and here too the resultant date for the Crucifixion would be the Passover of A.D. 29.

To sum up: the various dates and intervals, to the approximate determination of which this article has been devoted, do not claim separately more than a tentative and probable value. Perhaps their harmony and convergence give them some additional claim to acceptance, and at any rate do something to

secure each one of them singly—the Nativity in 7-6 B.C., the Baptism in A.D. 26-27, the Crucifixion in A.D. 29—from being to any wide extent in error.

The Chronology of the Apostolic Age.—The chronology of the New Testament outside the Gospels may be defined for the purposes of this article as that of the period between the Crucifixion in A.D. 29 (30) on the one hand, and on the other the persecution of Nero in A.D. 64 and the fall of Jerusalem in A.D. 70. Now the book of Acts, our only continuous authority for the period, contains three synchronisms with secular history which can be dated with some pretence to exactness, and constitute fixed points by help of which a more or less complete chronology can be constructed for at least the latter half of the apostolic age. These are the death of Herod Agrippa I. (xii. 23), the proconsulship of Gallio (xviii. 12), and the replacement of Felix by Festus (xxiv. 27).

1. The death of Herod Agrippa I. This prince, son of Aristobulus and grandson of Herod the Great, was made (i.) king over the tetrarchy which had been Herod Philip's, "not many days" after the accession of Gaius, March 16, A.D. 37; (ii.) ruler of the tetrarchy of Antipas, in A.D. 39-40; (iii.) ruler of the whole of Palestine (with Abilene) on the accession of Claudius at the beginning of A.D. 41. Josephus's *Jewish Wars* and *Antiquities* agree in the important *datum* that he reigned three years more after the grant from Claudius, which would make the latest limit of his death the spring of A.D. 44. The *Antiquities* also place his death in the seventh year of his reign, which would be A.D. 43-44. On the other hand, coins whose genuineness there is no apparent reason to doubt are extant of Agrippa's ninth year; and this can only be reconciled even with A.D. 44 by supposing that he commenced reckoning a second year of his reign on Nisan 1 A.D. 37, so that his ninth would run from Nisan 1, A.D. 44. On the balance of evidence the only year which can possibly reconcile all the data appears to be A.D. 44 after Nisan, so that it will have been at the Passover of that year that St. Peter's arrest took place.

After Agrippa's death Judaea was once more governed by procurators, of whom Cuspius Fadus and Tiberius Alexander ruled from A.D. 44 to 48; the third, Cumanus, was appointed in A.D. 48; and the fourth, Felix, in A.D. 52. Under Tiberius Alexander, *i.e.* in A.D. 46 or 47, occurred the great famine when the Antiochene church sent help to that of Jerusalem by the ministry of Barnabas and Saul (Acts xi. 30, xii. 25). Thus the earliest date at which the commencement of the first missionary journey (Acts xiii. 4) can be placed is the spring of A.D. 47. The journey extended from Salamis "throughout the whole island" of Cyprus, and on the mainland from Pamphylia to Pisidian Antioch, Iconium, Lystra and Derbe, at each of which places indications are given of a prolonged visit (xiii. 49, xiv. 3, 6, 7, 21). The same places were visited in reverse order on the return journey. Now it must be remembered that a sea voyage could never have been undertaken, and land travel only rarely, during the winter months, say November to March; and as the amount of work accomplished is obviously more than could fall within the travelling season of a single year, the winter of 47-48 must have been spent in the interior, and return to the coast and to Syria made only some time before the end of autumn A.D. 48. The succeeding winter, at least, was spent again at Antioch of Syria (xiv. 28). The council at Jerusalem of Acts xv. will fall at earliest in the spring of A.D. 49, and as only "certain days" were spent at Antioch after it (xv. 36) the start on the second missionary journey might have been made in the summer of the same year. The "confirmation" of the existing churches of Syria and Cilicia, and of those of the first journey beginning with Derbe (xv. 41, xvi. 5), cannot have been completed under several months, nor would the Apostle have commenced the strictly missionary part of the journey, in districts not previously visited, before the opening of the travelling season of A.D. 50. No delay was then made on the Asiatic side: it may still have been in spring when St. Paul crossed to Europe and began the course of preaching at Philippi, Thessalonica, Beroea and Athens which finally brought him to Corinth. The stay of eighteen months at the last-named place (xviii. 11)

will naturally begin at the end of one travelling season and end at the beginning of another, *i.e.* from the autumn of A.D. 50 to the spring of A.D. 52. From Corinth the Apostle went to Jerusalem to "salute the church," and then again to Antioch in Syria, where he stayed only for "a time" (xviii. 22), and soon left (on the third missionary journey, as conventionally reckoned), proceeding "in order" through the churches of the interior of Asia Minor. These journeys and the intervening halts must have occupied seven or eight months at least, and it must have been towards the end of the year when St. Paul established his new headquarters at Ephesus. The stay there lasted between two and three years (xix. 8, 10, xx. 31), and cannot have terminated before the spring of A.D. 55. From Ephesus he went into Europe, and after "much teaching" given to the churches of Macedonia (xx. 2), spent the three winter months at Corinth, returning to Philippi in time for the Passover (xx. 3, 6) of A.D. 56. Pentecost of the same year was spent at Jerusalem, and there St. Paul was arrested, and kept in prison at Caesarea for two full years, until Festus succeeded Felix as governor (xx. 16, xxiv. 27), an event which, on this arrangement of the chronology of the missionary journeys, would therefore fall in A.D. 58.

So far it has been shown, firstly, that the missionary journeys cannot have commenced before the spring of A.D. 47, and secondly, that between their commencement and the end of the two years' imprisonment at Caesarea not less than 11 full years must have elapsed. Consequently A.D. 58 appears to be the earliest date possible for the arrival of Festus, though a later date is not absolutely excluded. It is possible also that the first missionary journey should be placed in A.D. 48 instead of A.D. 47; so that the alternative is open that every date given above, from A.D. 47 to A.D. 58, should be moved on one year, with the result of placing Festus's arrival in A.D. 59.

It is now time to turn to the direct evidence for the dates of Gallio's proconsulship and of Festus's arrival as procurator, in order to test by them the result already tentatively obtained.

2. In a fragmentary inscription found recently at Delphi occur the words "in Gallio's proconsulship" and the words "Claudius being Imperator for the 26th time." We know from other sources that Claudius was Imp. XXIII. and XXIV. some time in 51, and Imp. XXVII. not later than Aug. 1, 52. He may therefore have become Imp. XXVI. some time in the first half of 52: but as the proconsul's year of office ran from May to May, the *data* still leave it open whether the proconsulship is to be placed between May, 51 and May, 52, or between May, 52 and May, 53, with some probability in favour of the former alternative. In other words, the inscription tallies very well with the date given above for St. Paul's appearance before Gallio, spring of 52, but is reconcilable at a pinch with a date one year later, spring of 53.

3. The replacement of Felix by Festus. This is the pivot date of St. Paul's later life, but unfortunately two schools of critics date it as differently as A.D. 55 and A.D. 60 (or 61). The former are represented by Harnack, the latter by Wieseler, whom Lightfoot follows. It can be said confidently that the truth is between these two extremes, for the arguments urged in each case appear less to prove one extreme than to disprove its opposite.

Arguments for the Later Date, A.D. 60 or 61.—(a) St. Paul, at the time of his arrest, two years before Felix's recall addresses him as "for many years past a judge for this nation" (Acts xxiv. 10, 27). It is certain that Felix succeeded Cumanus in A.D. 52, for Tacitus mentions Cumanus's recall under that year, Josephus immediately before the notice of the completion of Claudius's twelfth year (Jan. A.D. 53). It is argued that "many years" cannot mean less than six or seven, so that St. Paul must have been speaking at earliest in 58 or 59, and Felix will have left Judaea at earliest in 60 or 61. But Felix was at the time of his appointment *iamprius Iudaeae impositus* (Tacitus, *Annals*, xii. 54); and even Josephus implies that Felix had been in some position where the Jewish authorities could judge of his fitness when he tells us that the high priest Jonathan used to press on Felix, as a reason for urging him to govern well, the fact that he had asked for his appointment to the procuratorship (*Ant.* XX. viii. 5). If Felix had acted in some position of responsibility in

Palestine before 52 (perhaps for some time before), St. Paul could well have spoken of "many years" at least as early as the year A.D. 56.

(β) Josephus enumerates after the accession of Nero (Oct. 54) a long catalogue of events which all took place under the procuratorship of Felix, including the revolt of "the Egyptian" which was already "before these days" at the time of St. Paul's arrest, two years from the end of Felix's tenure. This suggests, no doubt, that the Egyptian rebelled at earliest in 54–55, and makes it probable that St. Paul's arrest did not take place before (the Pentecost of) A.D. 56; and it implies certainly that the main or most important part of Felix's governorship fell, in Josephus's view, under Nero. But as two years only of Felix's rule (52–54) fell under Claudius, this procedure would be quite natural on Josephus's part if his recall were dated in 58, so that two-thirds of his office fell under Nero.

The arguments, then, brought forward in favour of A.D. 60 or 61 do not do more than bring the recall of Felix down to 58 or 59.

Arguments for an Early Date, A.D. 55 or 56.—(a) Eusebius's *Chronicle* places the arrival of Festus in Nero 2, Oct. 55–56. But (i) Nero 2 is really, on the system of regnal years employed by Eusebius, Sept. 56–Sept. 57, (ii) it is doubtful whether Eusebius had any authority to depend on here other than Josephus, who gives no precise year for Festus—and if so, Eusebius had to fix the year as best he could.

(β) Felix, on his return to Rome, was prosecuted by the Jews for misgovernment, but was acquitted through the influence of his brother Pallas. Pallas had been minister and favourite of Claudius, but was removed from office in the winter following Nero's accession, 54–55: Felix must therefore have been tried at the very beginning of Nero's reign. But it would be a mistake to look upon Pallas's retirement as a disgrace. He stipulated that no inquiry should be made into his conduct in office, and was left for another seven years unmolested in the enjoyment of the fortune he had amassed. There is, therefore, every likelihood that he retained for some years enough influence to shield his brother.

Of these arguments, then, the first, so far as it is valid, is an argument for the summer, not of A.D. 55 or 56, but of A.D. 57 as that of the recall, while the second will apply to any of the earlier years of Nero's reign.

In the result, then, the point that Josephus catalogues the events of Felix's procuratorship under Nero cannot be pressed to bring down Felix's tenure as far as 60 or 61, but it does seem to exclude as early a termination as 56, or even 57. Conversely, the influence of Pallas at court need not be terminated by his ceasing to be minister early in 55; but it would have been overshadowed later on by the influence of Poppaea, who in the summer of the year 60 enabled the Jews to win their cause in the matter of the Temple wall, and would certainly have supported them against Felix.

The balance of the two lines of argument suggests the year 58 for the recall of Felix and arrival of Festus.

If St. Paul was arrested in 56, and appealed to Caesar on the arrival of Festus in 58, then, as he reached Rome in the early part of the year following, and remained there a prisoner for two full years, we are brought down to the early spring of 61 for the close of the period recorded in the Acts. That after these two years he was released and visited Spain in the west, and in the east Ephesus, Macedonia, Crete, Troas, Miletus and perhaps Achaëa and Epirus, is probable, in the one case, from the evidence of Romans xv. 28, Clem. *ad Cor.* v. and the Muratorian canon, and, in the other, from the Pastoral Epistles. These journeys certainly cannot have occupied less than two years, and it is more natural to allow three for them, which takes us down to 64.

Early evidence is unanimous in pointing to St. Peter and St. Paul as victims of the persecution of Nero, and tradition clearly distinguished the fierce outbreak at Rome that followed on the fire of the city in July 64 from any permanent disabilities of the Christians in the eye of the law which the persecution may have initiated. There is, therefore, no reason at all to doubt that both apostles were martyred in 64–65, and the date serves as a confirmation of the chronology adopted above of the imprisonment, release and subsequent journeys of St. Paul.

Investigation, then, of that part of the book of Acts which follows the death of Agrippa, recorded in chap. xii.—i.e., of that part of the apostolic age which follows the year 44—has shown that apparent difficulties can be to a large extent set aside, and that there is nowhere room between A.D. 44 and 64 for doubt extending to more than a single year.

But if the events of A.D. 44–64 can thus be fixed with a fair approximation to certainty, it is otherwise with the events of A.D. 29–44. Here we are dependent (i.) on the general indications given in the Acts, but these general indications can at best only lead to general conclusions. The most that we can say is that the first half of the book, down to xii. 24, covers the period from the Crucifixion to the death of Herod, A.D. 29–44, and that it is divided into three sections by the general summaries of vi. 7, ix. 31, xii. 24, just as the later half of the book is similarly divided at xvi. 5, xix. 20, xxviii. 31. But though these divisions are probably intended to be in a rough sense chronologically equal divisions, it is obvious that this rough equality cannot be pressed in detail.

(ii.) A nearer attempt to date at least the chronology of St. Paul's earlier years as a Christian could be made by the help of the Galatian Epistle if we could be sure from what point and to what point its reckonings are made. The apostle tells us that on his conversion he retired from Damascus into Arabia, and thence returned to Damascus; then after three years (from his conversion) he went up to Jerusalem, but stayed only a fortnight, and went to the regions of Syria and Cilicia. Then after 14 years (from his conversion? or from his last visit?) he went up to Jerusalem again to confer with the elder apostles. Most critics are now agreed that the 14 years are to be calculated from the conversion; and an increasing number of critics is coming round to the view that the two visits to Jerusalem are those recorded in Acts ix. 26 and xi. 30. If so, the epistle was written before, but apparently only just before, the Council of Acts xv., or in other words in the early months of A.D. 49. The 14 years reckoned back from the famine visit (c. A.D. 46) would bring us to A.D. 33 as the latest possible date for the conversion.

BIBLE, ENGLISH. The history of the vernacular Bible of the English race resolves itself into two distinctly marked periods, the one being that of Manuscript Bibles, which were secondary translations from the Latin Vulgate, the other that of Printed Bibles, which were, more or less completely, translations from the original Hebrew and Greek of the Old and New Testaments.

I. THE MANUSCRIPT BIBLE

The first essays in Biblical translation, or rather paraphrasing, assumed in English, as in many other languages, a poetical form. Even in the 7th century, according to the testimony of Bede (*Hist. Eccl.* iv. 24) Caedmon sang "of the creation of the world and the origin of man, and . . . of many other stories from Holy Writ." It is, however, doubtful whether more than the following lines can claim to be regarded as his genuine work.

Nu scylun hergan hefaenricaes uard,
Now we must praise of the heavenly kingdom the guardian,
Metudæ maecti cnd his modgidanc,
Of the maker the might and his heart-thought,
uerc uuldurfadur; sue he uundra gihuaes
the work of the father of glory; even as he of wonders each
eci Dryctin, or astelidæ.
the eternal Lord, the beginning established.
He aerist scop aelda barnum
He first created for mankind's children
heben til hrofe, haleg scepen.
heaven as a roof, the holy creator.
Tha middungeard, moncynnes uard,
Then the middle-world, of mankind the guardian,
eci Dryctin, aefter liadæ
the eternal Lord, afterwards established

firum foldu, frea allmectig.
for men the world, the lord almighty.

(Moore ms. of *Hist. Eccl.*, c. 737).

The first prose rendering of any part of the Bible—and with these we are mainly concerned in the present enquiry—originated in all probability in the 8th century, when Bede, the eminent scholar and churchman, translated chapters i.–vi. 9 of the Gospel of St. John into the vernacular, but no part of this rendering is extant. (*Hist. Eccl.* i., lxxv., ed. Plummer.)

Ninth and Tenth Centuries.—The 9th century is characterized by *interlinear glosses on the book of Psalms*, and towards its close by a few attempts at independent translation. Of these Psalters, glossing either the Roman or Gallican text, the oldest and most important is the so-called *Vespasian Psalter*, which was written in Mercia some time during the course of the first half of the 9th century (H. Sweet, *Oldest Engl. Texts*, E.E.T.S., No. 83, London, 1885).

To the late 9th or early 10th century a work may be assigned which is so far an advance upon preceding efforts as to be a real translation, not a mere gloss corresponding word for word with the Latin original. This is the famous *Paris Psalter*, a rendering of the first 50 Psalms (Vulg. i.–L. 10), contained in the unique ms. lat. 8824 in the Bibl. Nationale, Paris. The authorship of the version is doubtful, though tradition associates its name with King Alfred (ed. B. Thorpe, Oxford, 1835; J. D. Bruce, Baltimore, 1894). The first two verses of Psalm I. may serve as a specimen of the translation.

I. (1) Eadig by se wer be ne gaeð on ge þcaht
Blessed shall be the man who not walketh in the counsel
unrihtwisra, ne on þam wege ne stent synfulra,
of the unrighteous, nor in the way not standeth of the sinful,
ne on heora wolhæcendum setle ne sitt.
nor in their pestilential seat not sitteth.

(2) Ac his willa byð on Godes æc, and ymb his æc
But his will shall be in God's law, and about his law
byð smeagende daeges and nihtes.
he shall be meditating by day and night.

In the course of the 10th century the Gospels were glossed and translated. The earliest in date is a *Northumbrian Gloss on the Gospels*, contained in a beautiful and highly interesting ms. variously known as the *Lindisfarne Gospels*, the *Durham Book* or the *Book of St. Cuthbert* (ms. Cotton, Nero D. 4, ed. W. W. Skeat, Cambridge, 1871–87). The Latin text dates from the close of the 7th century, and is the work of Eadfrith, bishop of Lindisfarne (698–721). The English gloss was added about a century and a half later (c. 950) by one Aldred, who is held to have been the bishop of Durham of that name. The Lord's Prayer is glossed in the following way.—

Matthew vi. (9) Suæ ðonne iuih gie bidde fader urer ðu aŕð
Sic ergo uos orabitur + Pater noster qui es
ðu bist in heofnum in heofnas; sie gehalgad noma ðin; (10) to-cymcð
in caelis; sanctificetur nomen tuum; adueniat
ŕic ðin, sie willo ðin suæis in heofne 7 in eorðo (11) hlaf
regnum tuum, fiat uoluntas tua sicut in caelo et in terra. panem
userne oferwistlic sel us to daeg. (12) 7 forgef us scylda
nostrum super-substantialia[m] dā nobis hodie. et dimitte nobis debita
usra suæ uoc forgefon scyldgum usum. (13) 7 ne inlaed usih
nostra sicut nos dimittimus debitoribus nostris. et ne inducas nos
in costunge ah gefrig usich from yfle.
in tentationem sed libera nos a malo.

Of a somewhat later date is the celebrated *Rushworth Version of the Gospels* (ms. Bodl. Auct. D. ii. 9, ed. W. W. Skeat, *op. cit.*), which contains an independent translation of the Gospel of St. Matthew, and a gloss on those of St. Mark, St. Luke and St. John, founded upon the Lindisfarne glosses. From a note in the manuscript we learn that two men, Faerman and Owun, made the version. Faerman, a priest at Harewood or Harwood in Yorkshire, translated the whole of St. Matthew, and wrote the gloss of St. Mark i.–ii. 15, and St. John xviii. 1–3. The remaining part, a mere transcript, is Owun's work. The dialect of the translation of St. Matthew is Mercian.

A further testimony to the activity which prevailed in the field of Biblical lore is the fact that at the close of the century—probably about the year 1000—the Gospels were rendered anew for the first time in the south of England. Of this version, the so-called *West Saxon Gospels* (ed. W. W. Skeat, *op. cit.*), not less than seven manuscripts have come down to us. A note in one of these mss., Corp. Christ. coll., Cambridge, 140, states that “Aelfric wrote this book in the monastery of Bath,” but of this Aelfric nothing further is known. The Lord’s Prayer is rendered in the following way in these Southern Gospels:—

Matt. vi. (9) Fornustlice gebiddas eow þus; Faeder ure þu be eart on heofonum; si þin nama gehalgod, (10) to-becume þin rice; gewurþe þin willa on eorðan swa on heofonum. (11) ðine gedæghwamlican hlaf syle us to daeg. (12) forgyf us ðine gyltas swa swa wē forgyfas ðum gyltendum. (13) ne gelaed þu us on costnunge ac alys us of ycle soþlice.

Towards the close of the century parts of the Old Testament found a translator or rather paraphraser in Aelfric (*q.v.*), the eminent scholar and churchman. According to his own statement in *De veteri Testamento* (ed. Grein-Wülker, *Bibl. d. Ags. Prosa*, I., Cassel-Göttingen, 1872), written about 1010, he had at that period translated the Pentateuch, Joshua, Judges, Kings, Job, Esther, Judith and the Maccabees. His rendering is clear and idiomatic, and though he frequently paraphrases and abridges, the omissions never obscure the meaning or hinder the easy flow of the narrative.

Eleventh and Twelfth Centuries.—The 11th century with its political convulsions, resulting in the establishment of an alien rule and the partial suppression of the language of the conquered race, was unfavourable to literary efforts of any kind in the vernacular. With the exception of Aelfric’s late works at the very dawn of the century, we can only record two transcripts of the West-Saxon gospels as coming at all within the scope of our enquiry. In the 12th century the same gospels were again copied by pious hands into the Kentish dialect of the period.

Anglo-Norman Period.—The 13th century, from the point of view of Biblical renderings into the vernacular, is an absolute blank. French—or rather the Anglo-Norman dialect of the period—reigned supreme. There were certainly renderings of the Bible during the 12th, 13th and early 14th centuries, but they were all in French. Some of these translations were made in England, some were brought over to England and copied and recopied. Amongst the latter was the magnificently illuminated and widely spread *Norman Commentary on the Apocalypse*, some of the earliest copies of which were written in an English hand. In fact, before the middle of the 14th century the entire Old Testament and the greater part of the New Testament had been translated into the Anglo-Norman dialect of the period (mss. *Bibl. Nat. fr.* l. 9562; *Brit. Mus. Reg. I. C. III.*, cf. S. Berger, *La Bible française au moyen âge*, Paris, 1884, pp. 78 ff.).

When English finally emerged victorious towards the middle and latter half of the 14th century, it was for all practical purposes a new language, largely intermixed with French, differing from the language of the older period in sound, flexion and structure. It is evident that any Old English versions which might have survived the ravages of time would now be unintelligible; it was equally natural that as soon as French came to be looked upon as an alien tongue, the French versions hitherto in use would fail to fulfil their purpose, and that attempts should be made to render the Bible into the only language intelligible to the greater part of the nation—English.

Fourteenth Century.—As in the early Anglo-Saxon period Northumbria was the *lux mundi* and starting point of Biblical translations, so the north Midlands and the north were the first to turn their attention to Biblical lore after the great national revival of the 14th century. The earliest of these is possibly the *Midland Psalter*, once erroneously ascribed to William of Shoreham (ed. K. D. Bullbring, E.E.T.S., No. 97, London, 1891). It occurs in three mss., the earliest of which (*Brit. Mus. Add. 17376*), was probably written between 1340 and 1350. It contains a complete version of the book of Psalms, followed by 11 Canticles and the Athanasian Creed. The Latin original is a glossed version

of the Vulgate. In the English translation, however, the words of the gloss are often substituted for the strong and picturesque expressions of the Biblical text; in other respects the rendering is faithful and idiomatic.

The following two verses of the first Psalm may exemplify this:—

Ms. Brit. Mus. Add. 17376

I. (1) *Beatus uir, qui non abiit in consilio impiorum, et in uia peccatorum non stetit, et in cathedra iudicio pestilencie i falsitatis non sedit.* Blessed be þe man þat 3ede nou3t in þe counsell of wicked, ne stode nou3t in þe wale of sin3eres, ne sat nou3t in fals iugement.

(2) *Sed in lege domini uoluntas eius, et in lege eius meditabitur die ac nocte.* Ac hijs wyll was in the wyll of oure Lord, and he schal þenche in hijs lawe bope daye and ny3t.

Before the middle of the century Richard Rolle of Hampole (*q.v.*), the Yorkshire hermit, had translated the *Psalter* anew and provided it with a *Commentary* (ed. H. R. Bramley, Oxford, 1884). The work was undertaken, as the metrical prologue of one of the copies tells us (ms. Laud Misc. 286), “At a werthy recluse prayer, cald dame Merget Kyrkby.” The commentary, written in the northern dialect of the author’s Yorkshire home, gained immediate and lasting popularity and spread in numerous copies throughout the country, the peculiarities of the hermit’s harsh and vigorous speech being either modified or wholly removed in the more southerly transcripts. The translation, however, is stiff and literal to a fault, violating idiomatic usage and the proper order of words in its slavish adherence to the Latin. The following extracts may exemplify the hermit’s rendering and the change the text underwent in later copies:—

Ms. Univ. Coll. Oxford. 64

I. (1) Blisful man þe whilk oway 3ed nocht in þe counsaile of wicked, and in þe way of synful stode nocht, & in þe chaire of pestilens he nocht sate. (2) Bot in laghe of lord þe will of him; and in his laghe he sall thynke day & nyght.

Ms. Brit. Mus. Reg. 18.B. 21

I. (1) Blessed is þat man þat hap not gone in þe counsell of wicked men, and in þe weye of synful men hap not stonde, and in þe chaire of pestilence sat not. (2) But in þe lawe of our lorde is þe wille of him; and [in] his lawe we shall þynke day and nyght.

Approximately to the same period as these early renderings of the *Psalter* belongs a version of the *Apocalypse* with a *Commentary*, the earliest ms. of which (*Brit. Mus. Harl. 874*) is written in the dialect of the north Midlands. This commentary, for a long time attributed to Wycliffe, is really nothing but a verbal rendering of the popular and widely spread Norman Commentary of the *Apocalypse* (Meyer and Delisle, *L'Apocalypse en Français au XIII^e siècle*, Paris, 1901), which dates back as far as the first half of the 13th century, and in its general tenor represents the height of orthodoxy.

To the north Midlands or the north belongs further a complete version of the *Pauline Epistles* found in the unique ms. 32, Corp. Christ. coll., Cambridge, of the 15th century (ed. M. J. Powell, E.E.T.S., 1916).

Commentaries on the Gospels of St. Matthew, St. Mark and St. Luke were also translated into English by “a man of the north cuntre.”

A version of the *Acts and the Catholic Epistles* (ed. A. C. Paues, *A Fourteenth Century Biblical Version*, Cambridge, 1904) completes the number of New Testament books translated in the northern parts of England. It is found in several mss. either separately or in conjunction with a fragmentary *Southern Version of the Pauline Epistles, Peter, James and I. John* in a curiously compiled volume, evidently made, as the prologue tells us, by a “brother” for the use and edification of an ignorant “sister” or woman vowed to religion (ed. A. C. Paues, *op. cit.*). The translation of this, our only southern text, surpasses all previous efforts from the point of view of clearness of expression and idiomatic use of English, and, though less exact, it may even be said in these respects to rank equal with the Later or Revised Wycliffite version.

Apart from these more or less complete versions of separate books of the Bible, there existed also numerous renderings of the Lord’s Prayer, the Ten Commandments, Gospel Harmonies (e.g., M. Goates, *The Pepsian Gospel Harmony*, E.E.T.S., Oa. Serv. 157, 1922), translations of the epistles and gospels used in divine

service, and other means of familiarizing the people with Holy Scripture.

The Wycliffe Versions.—It is noteworthy that these early versions from Anglo-Saxon times onwards were perfectly orthodox, executed by and for good and faithful sons of the Church. It is first with the appearance of Wycliffe (*q.v.*) and his followers that the Bible in English came to be looked upon with suspicion by the orthodox party within the Church. For had not Wycliffe the hardihood of proclaiming the Bible, not the Church or Catholic tradition, as man's supreme spiritual authority? Did he not seek in consequence by every means in his power to spread the knowledge of "Goddess lawe" among the people? It is, therefore, in all likelihood to the zeal of Wycliffe and his circle of friends and adherents that we owe the two noble 14th-century translations of the Bible which tradition has always associated with his name, and which are moreover the *earliest complete* renderings that we possess of the Holy Scriptures in English (ed. Madden and Forshall, Oxford, 1850).

The first of these, the so-called *Early Version*, was certainly in the making about 1382; the second, or *Later Version*, was probably finished by the time its "General Prologue" was written "between February 1395 and February 1397." (See M. Deanesly, *The Lollard Bible*, Cambridge, 1920, p. 258.)

It is a matter of uncertainty what part, if any, Wycliffe himself took in the work. He is, however, definitely connected with the *Early Version* through the name of Nicholas of Hereford, one of his early and prominent adherents. For, miraculously, the translator's original copy and a coeval transcript of it are still extant in the Bodleian Library, Oxford (Bodl. 959, Douce 369). Both break off abruptly at Baruch iii. 19, the latter having at this place a note inserted to the following effect: *Explicit translationem Nicholay de herford.* In view of the magnitude of the undertaking there must have been a whole circle of translators, but no other name is recorded in connection with this noble work.

The *Early Version*, apart from its completeness, shows but little advance upon preceding efforts. The translation of the Old Testament as far as Baruch iii. 19 is stiff and awkward, sometimes unintelligible from a too close adherence to the Latin text; in the remaining parts the rendering is somewhat easier and more skilful, though even here Latinisms and un-English phrases abound.

It is small wonder, therefore, if a revision was soon found necessary and actually taken in hand within a few years of the completion of the *Earlier Version*. John Purvey, the eminent scholar and leader of the Lollard party after Wycliffe's death in 1384, is generally assumed to have taken a prominent part in this undertaking, and to have written the "General Prologue" where the principles of work adopted by the revisers have been clearly and forcibly laid down.

This *Revised or Later Version* is in every way a readable, correct rendering of the scriptures. It is far more idiomatic than the *Earlier*, having been freed from the greater number of its Latinisms; its vocabulary is less archaic. Its popularity admits of no doubt, for even now in spite of faggots and burning, in spite of the ravages of time and neglect, over 150 copies remain to testify to this fact. The following specimens may afford comparisons with previous renderings:—

Early Version

Psalms I. (1) Blisful the man, that went not awai in the counseil of vnpytouse, and in the wei off synful stod not; and in the chaier of pestilence sat not. (2) But in the lawe of the Lord his wil; and in the lawe of hym he shal sweteli thinke dai and nyȝt.

Late Version

I. (1) Blessid is the man, that ȝede not in the councel of wickid men; and stood not in the wei of synneris, and sat not in the chaier of pestilence. (2) But his wille is in the lawe of the Lord; and he schal bihenke in the lawe of hym dai and nyȝt.

The Lord's prayer is almost identical in the two versions:—

Late Version. Matt. vi. 9-13. Oure fadir that art in heuenes, halewid be thi name; thi kyngdom come to; be thi wille don in erthe as in heuene; ȝyue to vs this dai oure breed ouer othir substaunce, and forȝyue to vs oure dettis, as we forȝyue to oure dettouris; and lede vs not into temptacioun, but delyuere vs fro yuel. Amen.

Fifteenth Century.—The 15th century may well be described as the *via dolorosa* of the English Bible as well as of its chief

advocates and supporters, the Lollards (*q.v.*). Stern measures of suppression were directed not only against them but against "Goddess Lawe," the book for which they pleaded with such passionate earnestness. For all this, mss. of Purvey's Revision were copied and re-copied during this century, the text itself being apparently "approved" by the ecclesiastical authorities, when in the hands of the right people and if unaccompanied by controversial matter. Of the Lollard movement in Scotland but little is known, but a curious relic has come down to our times in the shape of a New Testament of Purvey's Revision in the Scottish dialect of the early 16th century. The transcriber was in all probability a certain Murdoch Nisbet, who also showed his reforming tendencies by adding to it a rendering of Luther's Prologue to the New Testament (ed. T. G. Law, Scot. Text Soc., Edinburgh, 1901-05).

II. THE PRINTED BIBLE

It is singular that while France, Spain, Italy, Bohemia and Holland possessed the Bible in the vernacular before the accession of Henry VIII, and in Germany the Scriptures were printed in 1466 and 17 times reprinted before Luther began his great work, yet no English printer attempted to put the familiar English Bible into type. No part of the English Bible was printed before 1525, no complete Bible before 1535, and none in England before 1538. Versions of the Scriptures so far noticed were all secondary renderings of the Vulgate, translations of a translation. It was only with the advent of the "new learning" in England that a direct rendering from the originals became possible. Erasmus in 1516 published the New Testament in Greek, with a new Latin version of his own; the Hebrew text of the Old Testament had been published as early as 1488.

William Tyndale.—The first to take advantage of these altered conditions was William Tyndale (*q.v.*), who, in his desire to rouse clerics and laymen alike to an understanding of the serious corruptions and decline of the Church, resolved to translate the New Testament into English. But he encountered powerful resistance to this project, in fact he found "that there was no place to do it in all englonde" (*Pref. to Genesis*, p. 396, ed. Parker Soc.). But undaunted he sought in May 1524 refuge for himself and his work first in Hamburg and then in Wittenberg, in which cities his translation of the New Testament must have been made. For in 1525 he was undoubtedly in Cologne engaged in printing at the press of Peter Quentel, a quarto edition of the New Testament, provided with prefaces and marginal glosses. But his work was stopped at the tenth sheet by Johann Cochlaeus (*q.v.*) an implacable enemy of the Reformation, who not only caused the printing to be discontinued, but also communicated with Henry VIII. and Wolsey, warning them to prevent the importation of such "pernicious merchandise." Tyndale managed, however, to escape higher up the Rhine to Worms, carrying with him some or all of the sheets which had been printed. Instead of completing Quentel's work he began, however, an octavo edition of the New Testament without prefaces or marginal glosses which was printed by the Worms printer Peter Schoeffer and actually finished before the quarto. Both editions reached England early in the summer of 1526 and were eagerly welcomed and bought. Such strong measures of suppression were, however, at once adopted against these perilous volumes that of the quarto only a single fragment remains (Matt. i-xxii. 12), now preserved in the British Museum (Grenville, 12179), of the octavo only one perfect copy (the title page missing) in the Baptist College at Bristol, and one imperfect in the library of St. Paul's Cathedral.

But Tyndale continued his labours with indomitable courage. In 1530 the whole of the Pentateuch was printed in Marburg by Hans Luft; it was provided with prefaces and marginal annotations of a strongly controversial character. The only perfect copy is preserved in the Grenville Library of the British Museum. In 1531 the *Book of Jonah* appeared, and in 1534 no fewer than three surreptitious reprints of the Worms edition of the new Testament. This is testified by George Jay in his *Apology*, who himself brought out a fourth edition of Tyndale's New Testament freed from many errors but with such alterations and new render-

ings as to arouse the indignation of Tyndale. The only remaining copy, a 16mo., is in the Grenville Library. To counteract and supersede all these unauthorized editions, Tyndale himself brought out his own revision of the New Testament with translations added of all the *Epistles of the Old Testament* after the use of Salisbury. It was published in 1534 at Antwerp by Martin Emperowr. Prologues were added to all books except the Acts and the Apocalypse, and new marginal glosses were introduced. Three copies of this edition are in the British Museum, and it was reprinted in 1841 in Bagster's *Hexapla*. In 1535 Tyndale once more set forth a revised edition printed at Antwerp by Godfried van der Haghen. In this, headings were added to the chapters in the Gospels and the Acts, and the marginal notes of the 1534 edition were omitted. Of this edition one copy is in the University Library, Cambridge, a second in Exeter college, Oxford, and a fragment in the British Museum. It is supposed to have been revised by Tyndale while in prison in the castle of Vilvorde, being the last of his labours in connection with the English Bible. For on Oct. 6, 1536, the execution took place of this martyr and "apostle of England." Yet he had not travailed or suffered in vain, for in the same year a small folio reprint of his revised edition of 1534 was brought out in *England*, the first volume of Scripture printed in this country. A perfect copy is found in the Bodleian Library. In later years, between 1536 and 1550, numerous editions of Tyndale's New Testament were printed, 21 of which have been enumerated and fully described by Francis Fry. (See Bibliography.)

"The history of the English Bible begins with the work of Tyndale and not with that of Wycliffe," says Dr. Westcott in his *History of the English Bible*, p. 316, and it is true that one of the most striking features of the work of Tyndale is its independence. He translated straight from the Hebrew and Greek originals, although the Vulgate and more especially Erasmus's Latin version were on occasion consulted. For his prefaces and marginal notes he used Luther's Bible freely, even to paraphrasing or verbally translating long passages from it.

Apart from certain blemishes and awkward and even incorrect renderings, Tyndale's translation may be described as a truly noble work, faithful and scholarly, though couched in simple and popular language. Surely no higher praise can be accorded it than that it should have been taken as a basis by the translators of the Authorized Version, and thus have lived on through the centuries up to the present day. The following specimen of the earliest translation of the Lord's Prayer direct from the Greek may prove of interest:—

[Tyndale 1525 (Grenville 12179)]

Matt. vi. 9-13. O our father which art in heven, haleded be thy name. Let thy kingdom come. Thy wyll be fulfilled, as well in erth, as hit ys in heven. Geve vs this daye our daily breade. And forgeve vs oure treaspases, even as we forgeve them whych treaspas vs. Lede vs nott into temptacion, but delyvre vs from yvell. Amen.

Miles Coverdale.—Meanwhile a *complete* English Bible was being prepared by Miles Coverdale (*q.v.*). As the printing was finished on Oct. 4, 1535, it is evident that he must have been engaged on the preparation of the work for the press at almost as early a date as Tyndale. Foxe states (*Acts and Mon.* v. 120) that Coverdale was with Tyndale at Hamburg in 1529, and it is probable that most of his time before 1535 was spent abroad, and that his translation, like that of Tyndale, was done and probably printed out of England. It is possible that the sheets were sent for binding and distribution to James Nicolson, the Southwark printer (H. Stevens, *Cat. of the Caxton Exhibition*, 1877, p. 88). This first of all printed English Bibles is a small folio in German black letter, provided with woodcuts and initials, the title page and preliminary matter in the only two remaining copies (British Museum and Holkham Hall) being in the same type as the body of the book. A second issue of the same date, 1535, has the title page and the preliminary matter in English type, and omits the words "out of Douche [German] and Latyn" found in the title of the first; a third issue bears the date 1536. A second edition in folio "newly oversene and corrected," was printed by Nicolson

in English type, in 1537; and also in the same year a third edition⁴ in quarto. On the title page of the latter were added the significant words, "set forth with the Kynges moost gracious licence."

Tyndale translated straight from the original Hebrew and Greek, Coverdale proclaims his dependence on "fyne sundry interpreters," that is, Luther, the Zürich Bible, the Latin Version of Pagninus, the Vulgate, and, in all likelihood, the English translation of Tyndale. (Wescott *op. cit.* p. 163.)

Though Coverdale's work was but a translation of translations, he showed great skill in the handling and use of his authorities, and moreover a certain delicacy and happy ease in his rendering of the Biblical text, to which we owe not a few of the beautiful expressions of our present Bible. The following extract from the edition of 1535 may serve as example of his rendering:—

The First Psalme. I. (1-2). Blessed is he man, he goeth not in the counsell of be ungodly: he abydeh not in the waye off synners, & syteth not in be seate of the scornfull. But delyteth in the lawe of be Lorde, & exercyseth himself in his lawe both daye and night.

It should be added that Coverdale's Bible was the first in which the non-canonical books were left out of the body of the Old Testament and placed by themselves at the end of it under the title *Apocripha*.

Matthew's Bible.—The large sale of the New Testaments of Tyndale, and the success of Coverdale's Bible, showed the London book-sellers that a new and profitable branch of business was opened out to them. Richard Grafton and Edward Whitchurch were the first in the field, bringing out a fine and full-sized folio in 1537, "truely and purely translated into English by Thomas Matthew." Thomas Matthew is, however, in all probability, an alias for John Rogers (*q.v.*), a friend and fellow-worker of Tyndale, and the volume is in reality no new translation at all, but largely a compilation from the renderings of Tyndale and Coverdale (Westcott *op. cit.* 169 *f.*). John Rogers's own work appears in a marginal commentary distributed throughout the Old and New Testament. The volume was printed in black letter in double columns. Three copies are preserved in the British Museum. In 1538 a second edition in folio appeared; it was reprinted twice in 1549 and again in 1551. It is significant that this Bible, like Coverdale's second edition, was "set forth with the kinges most gracious lycence."

Taverner.—Meanwhile a rival edition was published in 1539 in folio and quarto by "John Byddell for Thomas Barthlet" with Richard Taverner as editor. This was, in fact, what would now be called "piracy," being Grafton's *Matthew Bible* revised by Taverner, a learned member of the Inner Temple and famous Greek scholar. His revision, characterized by critical acumen and strong and idiomatic expressions, seems, however, to have had little or no influence on subsequent translators. It was only once, in 1549, reprinted in its entirety. Quarto and octavo editions of the New Testament alone were published in the same year, 1539, as the original edition, and in 1540 the New Testament in duodecimo. The Old Testament was reprinted as part of a Bible in 1551, but no other editions than those named are known.

The Great Bible, 1539.—It will have been observed that the translations of Holy Scripture which had been printed during these years (1525-1539) were all made by private men and printed without any real public or ecclesiastical authority. Some of them had indeed been set forth by the king's licence, but the object of this is shown by a letter from Archbishop Cranmer to Cromwell, touching Matthew's Bible. It is "that the same may be sold and read of every person . . . until such time that we, the bishops, shall set forth a better translation, which I think will not be till a day after doomsday." This letter was written on Aug. 4, 1537, and the impatient words at the end refer to a *duly authorized version* which was, in fact, at that very time in preparation, though not proceeding quickly enough to satisfy Cranmer. Coverdale had been placed at the head of the enterprise, the result of his labours being an entirely new revision, based on Matthew's Bible. In his revision he consulted the Latin Version of the Old Testament with the Hebrew text by Sebastian Münster, the Vulgate and Erasmus's editions of the Greek text for the New Testament.

This authorized Bible, planned on too large a scale evidently for the resources of the English presses, was begun in Paris in 1538 and after many vicissitudes completed in London, the Colophon stating that it was "Fynissshed in Apryll, Anno M. CCCC. XXXIX." It is a splendid folio Bible of the largest volume, and was distinguished from its predecessors by the name of the *Great Bible*. The title page states it to be "truly translated after the veryte of the Hebrew and Greke texts by þe dylygent studye of dyverse excellent learned men, expert in the forsayde tongues. Prynted by Rychard Grafton and Edward Whitchurch." This was the first of seven editions of this noble Bible which issued from the press during the years 1539-1541—the second of them, that of 1540, called *Cranmer's Bible*, from the fact that it contained a long preface by Archbishop Cranmer, having the important addition, "This is the Byble apoynted to the use of the Churches" on the title page. Seventy years later it assumed the form ever since known as the *Authorized Version*, but its Psalter is still embedded, without any alteration, in the Book of Common Prayer.

Meanwhile the closing years of Henry VIII's reign were characterized by restrictive measures as to the reading and use of the Bible. Tyndale's version was prohibited by an act of parliament, 1543; at the same time it was enacted that all notes and marginal commentaries in other copies should be obliterated, and that "no woman (unless she be noble or gentle woman), no artificers, apprentices, journeymen, servingmen, under the degree of yeomen . . . husbandmen or labourers" should read or use any part of the Bible under pain of fines and imprisonment (Burnet's *Ref.* i. 584).

In 1546 Coverdale's Bible was included in the proscription, the *Great Bible* being the only translation not interdicted. During Edward VI's reign there was a brief respite, but with the accession of Mary the persecutions of the English Bible and its friends were renewed. Cranmer suffered martyrdom at the stake, as John Rogers had done before him. Other prominent reformers, amongst them Coverdale, sought refuge in Geneva, the town of Calvin and Beza, where they employed their enforced leisure in planning and carrying out a new revision of the Bible. The first-fruits of these labours was a New Testament issued in June 1557, with an introduction by Calvin, probably the work of William Whittingham. The volume, in a convenient quarto size, printed in clear Roman type and provided with marginal annotations, was the first Bible which had the text divided into "verses and sections according to the best editions in other languages" (*cf.* "Address to the Reader").

The Geneva or "Breeches" Bible.—Whittingham's enterprise was, however, soon superseded by an issue of the whole Bible, which appeared in 1560, the so-called *Geneva Bible*, popularly also known as the *Breeches Bible*, from its rendering of Gen. iii. 7, "They sewed fig leaves together and made themselves breeches." Chief among the editors were William Whittingham, Anthony Gilby and Thomas Sampson, and the expenses towards printing and publication were borne by members of the congregation at Geneva. Based on the latest results of Hebrew and classical scholarship the revision gained immediate and lasting popularity, not only on account of its intrinsic merit but because of its quarto size and clear Roman type. Like Whittingham's earlier publication it had the division of chapters into verses and a marginal commentary which proved a great attraction to the Puritans.

The Bishops' Bible.—Though not allowed for use in the churches, the Geneva version with its ever growing popularity, became a serious rival to the authorized *Great Bible*. As a consequence, some time after the accession of Elizabeth, attempts were made to improve it. The initiative was taken by the learned and energetic Archbishop Parker, about 1563-65, who, according to Strype (Parker i. 414) "took upon him the labour to contrive and set the whole work agoing . . . by sorting out the whole Bible into parcels . . . and distributing these parcels to able bishops and other learned men, to peruse and collate each the books allotted to them . . . and they to add some short marginal notes for the illustration or correction of the text." Rules were provided for the guidance of the revisers, and the work was pushed forward with energy. On Oct. 5, 1568, the volume was ready for publication. It was a magnificent folio generally known as the

Bishops' Bible, but, though several editions were published in the course of time, it is doubtful whether the ecclesiastical authorities ever succeeded in entirely enforcing its use in the churches. In the homes the Geneva version reigned supreme. Even into the very text of this proud revision the smooth and well-known rendering of the Psalter of the *Great Bible* found its way. In the second edition of the Bishops' Bible, 1572, the two texts were actually printed side by side; in all later editions except one (1585) the older Psalter alone remained.

The Rhemes and Douai Version.—From the time of Tyndale onwards the translation of the Scriptures into English had been more or less an outcome of the great reformatory movements within the Church. It was not until Queen Elizabeth's reign that members of the Romanist party found it expedient to translate the Bible into the vernacular "for the more speedy abolishing . . . of false and impious translations put forth by sundry sectes" (*Preface to the Rhemes Version*).

The New Testament was published in 1582 in the English College of Rhemes, the Old Testament at Douai, 1609-10. Like the Wycliffite versions, this work, known as the *Rhemes and Douai Version*, was merely a secondary rendering from the Latin Vulgate, and in many places it suffered like these from extreme literalness and stilted and ambiguous renderings, *e.g.*, Luke xxii. 18, "I will not drink of the generation of the vine"; Phil. ii. 7, "But he exinanited himself." The Lord's Prayer is rendered in the following way:

Matt. vi. 9-13. Ovr Father which art in heauen, sanctified be thy name. Let thy Kingdom come. Thy wil be done, as in heauen, in earth also. Giue vs to day our supersubstantial bread. And forgiue vs our dettes, as we al-o forgiue our detters. And leade vs not into tentation. But deliuer vs from evil. Amen.

Its strongly Latinized vocabulary was, however, not without its influence on the next great venture in English translations of the Bible, the *Authorized Version*.

The Authorized Version, 1611.—The English Bible, which is now recognized as the *Authorized Version* wherever the English language is spoken, is a revision of the Bishops' Bible, begun in 1604, and published in 1611. It arose incidentally out of a conference between the High Church and the Low Church parties convened by James I. at Hampton Court Palace in Jan. 1604 a few months after he came to the throne.

No real opposition was offered to the proposal and the king himself sketched out on the moment a plan to be adopted. He "wished . . . for one uniform translation—professing that he could never yet see a Bible well translated in English—and this to be done by the best learned in both universities; after them to be reviewed by the bishops and the chief learned of the Church; from them to be presented to the privy council; and lastly to be ratified by his royal authority; and so this whole Church to be bound unto it and none other" (Cardwell, *History of Conferences*, p. 187 ff.). He also particularly desired that no marginal notes should be added.

The revisers were then chosen with extreme care and apparently without reference to party. Amongst them were some of the greatest scholars of the period, as Dr. Andrewes, afterwards bishop of Winchester, who was familiar with Hebrew, Chaldee, Syriac, Greek, Latin and at least ten other languages, while his knowledge of patristic literature was unrivalled; Dr. Overall, regius professor of theology and afterwards bishop of Norwich; Bedwell, the greatest Arabic scholar of Europe; and Sir Henry Savile, the most learned layman of his time. These "learned men, to the number of four and fifty" (Cardwell, *Doc.* Annals, II. 84) were divided into six companies, and set down to their task. An elaborate set of rules was drawn up for their guidance, which contained a scheme of revision as well as general directions for the execution of their work. This is one of the very few records that remain of their undertaking (Burnet, *Hist. of Reformation* ii., p. 368, 1861, reprinted by Westcott, *op. cit.* p. 114 ff.). A few of these may be quoted:—

(1) "The ordinary Bible read in the Church, commonly called 'the Bishops' Bible' to be followed and as little altered as the truth of the original will permit.

(2) The names of the prophets and the holy writers, with the other names of the text to be retained as nigh as may be, accordingly as they were vulgarly used.

(3) The old ecclesiastical words to be kept, viz., the word *Church* not to be translated congregation, etc. . . .

(4) These translations to be used when they agree better with the text than the Bishops' Bible; viz., Tyndale's, Matthew's, Coverdale's, Whitchurch's, Geneva. . . ."

It is not possible to determine how far all these rules were followed. All we know of the way this noble work was carried out is contained in the preface, where Dr. Miles Smith, in 1612 bishop of Gloucester, in the name of his fellow-worker, gives an account of the manner and spirit in which it was done. "The worke hath . . . cost the workemen, as light as it seemeth, the paines of twise seuen times seuentie two days and more . . . truly (good Christian Reader) we never thought from the beginning, that we should neede to make a new Translation, nor yet to make of a bad one a good one . . . but to make a good one better. . . . To that purpose there were many chosen, that were greater in other men's eyes than in their owne, and that sought the truth rather than their own praise. . . ."

From the above it appears that the actual work of revision occupied about two years and nine months, an additional nine months being required for the final preparation for press. The edition appeared at length in 1611, having been printed in London by Robert Barker. Since that time many millions of this revised translation have been printed, and the general acceptance of it by all English-speaking people of whatever denomination is a testimony to its excellence.

Still the work of improving and correcting went on through the centuries, and a modern copy of the Authorized Version shows no inconsiderable departure from the standard edition of 1611.

The Revised Version.—More ambitious attempts at amending the new version were not lacking, but they all proved fruitless, until in Feb. 1870 the Convocation of Canterbury appointed a committee to consider the subject of revision. The report of this committee, presented in May, was adopted, to the effect "that Convocation should nominate a body of its own members to undertake the work of revision, who shall be at liberty to invite the co-operation of any eminent for scholarship, to whatever nation or religious body they may belong"; and shortly afterwards two companies were formed for the revision of the Authorized Version of the Old and New Testaments.

Negotiations were opened with the leading scholars of the Protestant denominations in America, with the result that similar companies were formed in the United States. The work of the English revisers was regularly submitted to their consideration; their comments were carefully considered and largely adopted, and their divergences from the version ultimately agreed upon were printed in an appendix to the published work. Thus the Revised Version was the achievement of English-speaking Christendom as a whole; only the Roman Catholic Church, of the great English-speaking denominations, refused to take part in the undertaking. The Church of England, which had put forth the version of 1611, fitly initiated the work, but for its performance most wisely invited the help of the sister Churches. The delegates of the Clarendon Press in Oxford, and the syndics of the Pitt Press in Cambridge, entered into a liberal arrangement with the revisers, by which the necessary funds were provided for all their expenses. On the completion of its work the New Testament company divided itself into three committees, working at London, Westminster and Cambridge, for the purpose of revising the Apocrypha.

The work of the Old Testament company was different in some important respects from that which engaged the attention of the New Testament company. The received Hebrew text had undergone but little emendation, and the revisers had before them substantially the same Massoretic text which was in the hands of the translators of 1611. It was felt that there was no sufficient justification to make any attempt at an entire reconstruction of the text on the authority of the versions. The Old Testament revisers were therefore spared much of the labour of deciding between different readings, which formed one of the most important duties

of the New Testament company. But the advance in the study of Hebrew since the early part of the 17th century enabled them to give a more faithful translation of the received text. The value of their work is evident, especially in Job, Ecclesiastes and the prophetic books.

It is the work of the New Testament committee which has attracted most attention, whether for blame or praise. The revisers' first task was to reconstruct the Greek text, as the necessary foundation of their work. In this difficult duty they were no doubt influenced by Westcott and Hort's edition of the New Testament. But it is scarcely necessary to say that the Revised Version is not the work of one or two scholars. Different schools of criticism were represented on the committee, and the most careful discussion took place before any decision was formed. Every precaution was taken to ensure that the version should represent the result of the best scholarship of the time, applied to the work before it with constant devotion and with the highest sense of responsibility. The changes in the Greek text of the Authorized Version when compared with the *textus receptus* are numerous, but the contrast between the English versions of 1611 and 1881 is all the more striking because of the difference in the method of translation which was adopted. The revisers aimed at the most scrupulous faithfulness. They adopted the plan—deliberately rejected by the translators of 1611—of always using the same English word for the same Greek word. "They endeavoured to enable the English reader to follow the correspondences of the original with the closest exactness, to catch the solemn repetition of words and phrases, to mark the subtleties of expression, to feel even the strangeness of unusual forms of speech."

The revision of the New Testament was completed in 407 meetings, distributed over more than ten years. It was formally presented to Convocation on May 17, 1881. The revision of the Old Testament occupied 792 days, and was finished on June 20, 1884. The revised Apocrypha did not make its appearance until 1895.

The text of the Revised Version is printed in paragraphs, the old division of books into chapters and verses being retained for convenience of reference. By this arrangement the capricious divisions of some books is avoided. Various editions of the New Version have been published, the most complete being the edition of the whole Bible with marginal references. These references had their origin in the work of two small sub-committees of the revisers, but they received their present form at the hands of a specially appointed committee. The marginal references given in the original edition of the Authorized Version of 1611 have been retained as far as possible.

The work of the revisers was received without enthusiasm. It was too thorough for the majority of religious people. Partisans found that havoc had been played with their proof texts. Ecclesiastical conservatives were scandalized by the freedom with which the traditional text was treated. The advocates of change were discontented with the hesitating acceptance which their principles had obtained. The most vulnerable side of the revision was that on which the mass of English readers thought itself capable of forming a judgment. The general effect of so many small alterations was to spoil the familiar sonorous style of the Authorized version. The changes were freely denounced as equally petty and vexatious; they were, moreover, too often inconsistent with the avowed principles of the revisers. The method of determining readings and renderings by vote was not favourable to the consistency and literary character of the Version. A whole literature of criticism and apology made its appearance, and the achievement of so many years of patient labour seemed destined to perish in a storm of resentments. On the whole, the Revised Version weathered the storm more successfully than might have been expected. Its considerable excellences were better realized by students than stated by apologists. The hue and cry of the critics largely died away, and was replaced by a calmer and more just appreciation.

BIBLIOGRAPHY.—The principal works dealing with the separate versions have been referred to in the text of the article. The following authorities may also be cited.—

For the version as a whole: F. G. Kenyon, *Our Bible and the Ancient Manuscripts* (1911); J. H. Lupton, article on "English Versions," in *Hasting's Dict. of the Bible*, extra vol. 1904; B. F.

Westcott, *A General View of the History of the English Bible*, 3rd ed. revised by W. Aldis Wright (London, 1905).

For the Manuscript Bible: The historical accounts prefixed to Bagster's issue of *The English Hexapla* and of Forshall and Madden's edition of the *Wycliffite Versions* are to a large extent antiquated. The only trustworthy authority on the Anglo-Saxon Bible is A. S. Cook's "Introduction on Old English Biblical Versions" in his *Biblical Quotations in Old English Prose writers*, I. (London, 1898; II. New York, 1903), with a full bibliography.

For the 14th and 15th centuries, see M. Deanesby, *The Lollard Bible and other Mediaeval Biblical Versions* (1920), with copious bibliography; A. C. Paues, *A Fourteenth Century English Biblical Version*, consisting of a Prologue and Parts of the New Testament, with some *Introductory Chapters on Middle English Biblical Versions* (Prose-translations) (1902), and *A Fourteenth Century Biblical Version* (1904), which has an introductory chapter on Middle English translations; Hope Allen, *The Canon of Richard Rolle*; D. Everett, "The Middle English Prose Psalter of Richard Rolle of Hampole," *Mod. Lang. Review*, XVII. 217-227, 337-350, (1922), XVIII. 381-393 (1923); H. B. Workman, *John Wyclif: a study of the English Med. Church* (1926).

H. J. Darlow and H. F. Moule (1903-11); R. Demans, *William Tyndale, a biography, being a contribution to the early History of the Engl. Bible.*, rev. by R. Lovett (1922); F. Fry, *The Bible by Coverdale*, 1867; *Description of the Great Bible, 1539* (1865); *Bibliographical Descriptions of the Editions of the New Testament* (1878); A. W. Pollard, *Matthew i-xxii . . . by William Tyndale, 1525. Facsimile . . . with an Introduction* (1926), containing also a reprint of Matth. v. acc. to Tyndale (1535), the Great Bible (1539), Geneva (1560), Bishops' (1572), Rhemes (1582), Authorized (1611); *idem*, *The Holy Bible. An exact reprint . . . of the Authorized Version . . . with an Introduction* (1911); *idem*, *A facsimile . . . of the Authorized Version . . . with an Introduction and illustrative documents* (1911).

For the Revised Version: J. B. Lightfoot, *On a Fresh Revision of the English New Testament* (London, 1871; 3rd ed 1891); Westcott, *Some Lessons of the Revised Version* (London, 1897); Kennedy, *Ely Lectures on the Revised Version* (London, 1882). The Revisers fully explained their principles and methods in the Preface. The American Committee of Revision issued an historical account of their work (New York, 1885). The case against the Revisers is ably stated in *The Revision Revised*, by Dean Burgon (London, 1883). The literary defects of the Version are elaborately exhibited by G. Washington Moon in two works: *The Revisers' English* (London, 1882), and *Ecclesiastical English* (London, 1886). See also *Some Thoughts on the Textual Criticism of the New Testament*, by G. Salmon, D.D. (London, 1897); Bishop Ellicott's *Charge* (1901). The Greek Text of the New Testament adopted by the Revisers was edited for the Clarendon Press by Archdeacon Palmer (Oxford, 1881). Parallel editions of the Bible, showing both the Authorized and Revised Versions, a large-type edition for public use, a reference edition, and (1900) a "Two Version" edition, have been issued by one or both the University Presses. (A. C. P.; H. H. H.)

III. THE BIBLE AND ENGLISH LITERATURE

The purpose of this study is to give an indication of the principal ways in which the Bible, in its various English versions, has influenced the development of English prose and English literature generally. The history of the English Bible is dealt with elsewhere; here, however, we must recall some of the more important relevant facts. There are two periods in the history of the English versions: one during which English translations of the Bible, or parts of it, made directly from the Latin Vulgate, circulated in manuscript form; the other beginning with the circulation of printed Bibles, which were translations of the original Hebrew and Greek of the Old and New Testaments.

One of the marvels of history, it has been said, is the rapidity and thoroughness with which Christian civilization was adopted by the English; from the writings which have survived, it would seem as if man strove to forget that England had ever been heathen. Augustine landed in 597; and within 50 years, native versions of the Psalms and Gospels were in circulation. The earliest version still extant is one of the Psalms by Aldhelm of Malmesbury (d. 709). Next in date comes the interlinear English translation added about 950 to the famous "Lindisfarne Gospels," which had been written in Latin about 680, and the similar translation added to the "Rushworth Gospels." To the 10th century belongs also the version of the Psalms by Aelfric of Canterbury (d. 1005), and versions of the Gospels and other books which have been supposed to be by the same hand. All the translations

which have been mentioned are in the ancient form of the English language, which has been called "Anglo-Saxon." In estimating their literary influence, we must bear in mind that although the surviving Old English poetry is almost entirely Christian, the images and diction are mainly those of the older heroic poetry; and Christ and the saints are often introduced in the guise of northern warriors. Incongruous as this may appear in modern ages, it is an interesting example of the reaction of inherited national or racial feeling on religious ideas and images sprung from a different source.

The 14th Century.—The vernacular tongue of the country was fundamentally, though gradually, altered through its contact with the French spoken by the upper classes, and new versions of the Bible became necessary. From statements made later by Cranmer, More, Foxe, and others, we learn that a number of such versions had been made; but only fragments now remain—the most important being two versions of the Psalms, one by William of Shoreham, Kent, the other by Richard Rolle of Hampole (d. 1349). This version, with the other writings of Richard Rolle and his school, was very popular, and materially influenced the literary development of contemporary English. The great rhyming chronicle of biblical and other stories, the *Cursor Mundi*, which circulated widely, had the same effect. The author insists on English for the English, not as a truism but as a novelty for which sound reasons must be given; but it is typical "Middle English" in which he writes. The two great versions (sometimes called "Wickliffite versions") which were made later in the 14th century, have survived in their entirety; viz., that of which John Wickliffe and Nicholas of Hereford were the principal translators, and that of John Purvey, resembling the former but making no reference to it. These were the last English Bibles issued during the period in which it was a translation from the Latin Vulgate, and before the invention of printing was applied to its circulation. These versions and Wickliffe's own non-academic writings made English the popular language of religious thought and feeling (for different views of the attitude of the Church to the circulation of the Wickliffite Bibles, see F. A. Cardinal Gasquet, *The Old English Bible*, and M. Deanesley, *The Lollard Bible*, 1920). Wickliffe appealed to the people of England in the speech of the people, sending out pamphlets and sermons couched in short clear sentences, full of the homely words used in his own Bible. In his work the literary expression of popular religion at this period reaches its height in the realm of prose, as in William Langland it reaches its height in the realm of poetry. In the dreams and ideals of the *Piers Plowman* poems—whether Langland be their sole author or not—a voice speaks from the heart of the people themselves; the poems are in the old alliterative English verse, and the wayfaring man could understand them. But there moves in them a prophetic impulse closely akin to that of the prophets of Israel. In them we hear the social movement—as in Wickliffe the distinctly religious movement—of revolt, in the name of the Bible, against Roman Christianity. When we turn from Wickliffe and Langland to the greatest figure in the creative literature of the age, it is not possible to say how far the influence of the Bible was effective in the development of his mind and art from his early imitations of French models to the latest and most original of the *Canterbury Tales*, with their rich humanity and simplicity of diction. But the author of these tales was well versed in "Christes lore and his apostles twelve."

The promise of a new era in English literature, arising from the later years of the 14th century, was not fulfilled. We are concerned only with lines of influence which can be traced directly to the English Bible. The most original and powerful poetry of the 15th century was composed in popular forms for the ear of the common people—songs, carols, popular ballads. Of those dealing with religious subjects, some are curious and delightful blendings of religious worship and aspiration, with earthly tenderness for the embodiments of helpless infancy and protective motherhood, which gave Christianity so much of its power over the affections and imagination of the middle ages. We can only mention the additions made in the 15th century to the ancient cycles of Scripture plays, the so called "mystery plays" (on these, see DRAMA; and

for a brief, but instructive introduction to the whole subject, R. N. V. Bloor, *Christianity and the Religious Drama*, 1927).

The 16th century forms, as it were, a watershed in the life of the nation, and in its literature as the expression of its life. From the age of Elizabeth we seem, more thoroughly than in any earlier time, to find in history men who are in all things our own fellows. Spenser and Shakespeare, Hooker and Raleigh, stand to us in a relation different from that in which Caedmon or even Chaucer stands. And, above all, the 16th century gave us in the English Bible a model of the language which has been the chief literary, as well as the chief religious food of millions of Englishmen. It came at a psychological moment in the moral and political development of the people. It not only entered into the warp and woof of literature, but served to give pointed emphasis and expression to the new social and religious impulses which were moving in the country. The reign of Elizabeth is itself the most marked epoch in English literature. The stirring of men's minds which led to the great political and religious events of the age, led also to the outburst of a whole literature in prose and verse. The English drama began, modern English theology began, the writing of history in the modern sense and in the English language began. As regards the English Bible, the first-fruits of the printing press had already been achieved in the New Testament and the Pentateuch of William Tyndale, published in England in 1526 and 1530 respectively. Tyndale's work, and the subsequent publication of Coverdale's Bible (1535), the "Great Bible" (1539), the Geneva Bible (1560), and the "Bishops' Bible" (1568) is described elsewhere. At length, in order to secure one uniform translation, a large committee of the most competent scholars in the country was appointed in 1604, to revise previous versions, taking the Bishops' Bible as the basis. The world-famous "Authorized Version" was published in 1611, "the late fruit of the long toil which had begun with the work of Tyndale, and, on the side of style, with the Wycliffite translations." More scholarly than all the preceding versions which it utilized, it won its incomparable form, not so much because of "the grand style which was in the air," which would have been the worst of models, as because the style had already been tested and ennobled by generations of translators.

Characteristics of Biblical Literature.—In any description of the literary influence of the English Bible we are not specially concerned with the literary forms which can be distinguished in the writings of the Old and New Testaments themselves (see, for example, R. G. Moulton, *The Modern Reader's Bible* and *The Literary Study of the Bible*); but there are some aspects of that literature which must be borne in mind for our present purpose. "Few abstract terms exist in ancient Hebrew, and no compound words. Abstraction and constructive power are almost as absent from the grammar and syntax as from the vocabulary. The subordination of clause to clause, in which the subtlety and flexibility of other languages appears, is hardly found; but to the end, both in prose and verse, the clauses are almost invariably strung together by the bare copulas *and* and *then* in a co-ordination which requires both skill and spirit to redeem it from monotony." (Sir G. A. Smith in *The Legacy of Israel*, edited by E. A. Bevan and C. Singer, 1927.) Ancient Hebrew is the dialect—concrete and even sensuous—of a few small tribes of herdsmen, peasants, and warriors, which the literary genius of a religiously and morally gifted people made into the vehicle of the sublimest truths, the most spiritual ethics, and, in the end, of a gospel for mankind. Part of the power of the English Bible is that it reflects these qualities so faithfully. Another characteristic is important for our present purpose, although it is one of material rather than of literary form. The Hebrew mind was entirely unfamiliar with the idea of evolution or development: "it fixed upon results rather than upon processes; things which came into being only gradually appeared to it as the offspring of a word, of a moment. In Deuteronomy, the effect of centuries of ethical influence on the law and ritual of Israel is presented as a single discourse of Moses. To the Hebrew, power and authority were personal and immediate, the effect of a single fiat or proclamation, and secondary causes were ignored" (*op. cit.*). The Old Testament is the surviving

literature of such a people during the intensely creative periods of their religious experience; and, when we pass to the New Testament, so far as literary atmosphere is concerned, the writers of the first three gospels belong to the Old Testament school. But in Acts we are emerging into a new world, which begins to be realized, not only in doctrine, but in substance and form, in all the epistles, especially in those of Paul; and in this sense it is true that "when we pass from Proverbs and Job to St. John and Romans and Hebrews, we have passed from the world of Solomon to the world of Socrates." The Old Testament is the literature of a nation; the New Testament is the literature of a movement, gathering round one central and supreme personal figure and spreading out into the world of Greece and Rome.

The Puritans.—This is the literature which, bound together within the covers of a single volume, had become the book of books in England before the end of Elizabeth's reign, and which, for most of the 17th century, was the one book familiar to every Englishman. It was read in churches and read at home; and everywhere its words, as they fell on ears not deadened by custom, kindled a startling enthusiasm. There was more than one side to this. The Bible was accepted in the new English version in its baldest and most literal sense, as all equally "the Word of God," above all by the Puritans, those most typical of Protestants. They found a close analogy between their fortunes and those of Israel of old. The immediate influence of the national translation of the Bible was in the life rather than the literature of England. The English Reformation (and every important aspect of it was of native origin and can be traced at least as far back as Wickliffe) was political as well as doctrinal and imaginative. But the debating weapons of vernacular English were sharpened in the pamphlet battles which ensued (see W. B. Selbie, "The Influence of the Old Testament on Puritanism," in *The Legacy of Israel*). The powers of the same style for religious appeal were proved in the "blunt, sound rhetoric and forthright jests" of Latimer's sermons, with their essentially biblical note. Foxe's *Book of Martyrs* is a type of early Protestant English; but reforming divines were not "men of letters." Their spirit comes out in the byways of literature, as in Spenser's *Shepherd's Calendar*.

As regards the Anglican Church, the fruit of the struggle was not long delayed. In the sermons of Fisher (d. 1535) and Cranmer (d. 1556), we see the beginnings of the work continued by Hooker (d. 1600), which made of the reformed Church a school where English prose was well trained for the purposes of learning and oratory, and as a medium of poetic feeling. Jeremy Taylor (d. 1667) one of the first pleaders for toleration in his *Liberty of Prophesying*, was the ideally humane Anglican of his age; while the lineage of Anglican strength was carried on by Isaac Barrow (d. 1677), John Tillotson (d. 1694), William Sherlock (d. 1707), and Robert South (d. 1716). For such men the Church came first, though the Bible was behind it. On the other hand, the Puritan temper is ideally represented in *Paradise Lost*. The strength of the Bible is assimilated without its tenderness. The subject is biblical, the form that of the classical epic, the doctrine Protestant, though not orthodox, and the feeling strangely divided by the claim of the vanquished—even Satan—to judge and deny the victor. In *Samson Agonistes*, the subject is biblical, the form that of a Sophoclean tragedy, and the suffering portrayed is Milton's own. Milton stands apart; but noble varieties of vernacular prose are found in the Puritans of the Restoration: John Bunyan (d. 1688), George Fox (d. 1690), Richard Baxter (d. 1691), and John Howe (d. 1706) had the English Bible behind them, which gave them the best of their inspiration. Baxter and Howe were also men of learning; but Bunyan, whose reading was the Bible and the popular allegories of giants, pilgrims, and adventure, stands out as the greatest literary artist of them all, bringing into the service of spiritual intensity, a keen, humorous vision and a power of simple speech consummately chosen.

The 18th Century.—When we pass to the 18th century, we soon find ourselves in a changing world. The charm of the literature is of the national and sociable kind. It is, before all else, the age of prose; not of the greatest prose, but an age where every variety of English prose is brilliantly exemplified. Little illus-

trative material, for our present purpose, can be derived from it. Religious thought, among educated people, was ruled by the spirit of Locke's *Essay Concerning Human Understanding*. In other words, thought was governed by a great respect for facts and realities; and the most real fact, from which we cannot get away, with which we must always start and to which we must ever return, was the *infinite* machine called Nature. Paley argued that we can reason from the universe to its Divine Maker, as we can from any other machine to its human maker. Theism was based on the world of sense-perception; and the nature of the Deity was further defined by appeal to revelation, guaranteed by the miracles believed to have accompanied it. The same reliance on tangible facts emerged in the realm of morality, the true ground of which is declared by Locke to be "the will and law of a God who sees men in the dark, has in his hands rewards and punishments and power to call to account the proudest offender." An intellectual atmosphere of this kind fails to supply the life-breath of vital religion. In the missionary work of John Wesley (d. 1791) and George Whitefield (d. 1770), the fervid gospel of personal religion and personal salvation was borne to the neglected masses, with the Bible once more in the foreground, and found its literary expression in the hymns of Charles Wesley (d. 1788). These events, great in themselves, were still greater in their importance as signs of new and vitalizing currents entering into the religious life and thought of England; and from this time onwards it is scarcely possible to separate the influence of the Bible from the many streams of feeling and belief which made "not so much a movement as a spirit afloat, rising up in hearts where it was least suspected, and working itself, though not in secret, yet so subtly and impalpably as hardly to admit of encounter on any ordinary human modes of opposition" (J. H. Newman, *History of My Religious Opinions*, 1839, ch. iii.). For the Bible it meant no abatement of reverence for its religious value, but a revival of the old natural human feeling for its great humanities, such as had found expression in the ancient English religious poetry and in the mystery plays; but which proceeded now from a far wider and deeper range of knowledge and experience.

The 19th Century.—In the opening years of the 19th century this was not apparent. Keats died in 1821, Shelley in 1821 and Byron in 1824. In 1825 Charles Lamb was 50 years old, and Coleridge 53; and of the two greatest names in the literature of the time, Scott had already written most of his Waverley Novels, and Wordsworth had done most of his influential work. But John Ruskin was a child of six; Charles Dickens and Robert Browning were boys of 13; Charles Darwin, Alfred Tennyson, and William Ewart Gladstone, boys of 16; James Martineau was a young man of 20, as was Richard Cobden; Ashley (earl of Shaftesbury) and John Henry Newman were young men of 24; and Carlyle, aged 31, was beginning to feel that he had a message to deliver to mankind. It is a matter of common knowledge that these are only some of the leaders of an army of pioneer workers who have, directly or indirectly, made the literature of the 19th century what it has been. In this the influence of the Bible has been reflected back in the form of a searching light on its own contents. It is no longer startling to say (as it was when Benjamin Jowett said it in *Essays and Reviews*, 1853) that the Bible must be interpreted like any other book. The obviously different strata in the complex elements composing it have been distinguished. Questions are asked about its value as an explanation of the origin of things; about the value of its contributions to our knowledge of human history; about its religious value; about its literary value; but these are different questions. The answer to one of them does not prejudice the answer to another. And abundant illustrative proof might be given showing that in the literature of the 19th century the Bible has made itself felt in such a way as to produce an assured conviction about it; whatever else it may be, the Bible, as a whole, is the greatest and, indeed, the unique record of man's religious experience; and above all, whatever else may or must be believed of the Founder of Christianity, his historic personality and teaching have made the New Testament the richest mine of religious and moral insight and inspiration which has been given to the world.

The critical and other considerations arising from the revision of the Authorized Version, carried through by committees of convocation, fall outside the scope of this article. The Revised Version of the N.T. was issued in 1881 and that of the O.T. in 1884. Translations, altogether independent of the Authorized Version, have been published by J. Moffatt (*The New Testament*, 1913; *The Old Testament*, 1924), and by W. G. Rutherford (*St. Paul's Epistle to the Romans*, 1900; *St. Paul's Epistles to the Thessalonians and Corinthians*, 1908). The following books deal directly or indirectly with the subject of the foregoing article: A. S. Peake (edit. by), *The People and the Book* (1925), illuminating essays on the O.T.; S. H. Mellone, *The New Testament and Modern Life* (1921); R. G. Moulton, *The Literary Study of the Bible* (1901); J. H. Gardiner, *The Bible as English Literature* (1906); E. von Dobschütz, *The Influence of the Bible on Civilization* (1913). See also A. S. Cook, *Biblical Quotations in Old English Prose Writers* (2 vols., 1898, 1903); J. Moffatt, *The Bible in Scots Literature* (1920); C. Wordsworth, *Shakespeare's Knowledge and Use of the Bible* (1864). (S. H. M.)

BIBLE CHRISTIANS, one of the denominations now merged in the United Methodist Church (see UNITED METHODISTS), so called because its early preachers appealed solely to the Bible in confirmation of their doctrines. The denomination arose in the agricultural districts and fishing villages of north Cornwall and Devon; a district only slightly influenced by John Wesley and the original Methodist movement. The founder was William O'Bryan (afterwards Bryant), a Methodist lay preacher of Luxillian, Cornwall. Finding that the people had no evangelical preaching he began an itinerary to supply the need. The coastmen were expert smugglers and wreckers, the agriculturists were ignorant and drunken, the parish clergy were slothful, in many cases intemperate, and largely given to fox-hunting. Only in a parish or two was there any approach to religious ministry. O'Bryan commenced his labours in North Devon, and in 1815 a small society was formed at Lake Farm, Shebbear. The movement had the seeds of great vitality in it. In 1819 the first conference was held at Launceston. By this time the work had spread through Cornwall; and shortly afterwards Kent, Northumberland, and the Channel Islands appeared on the list of stations. For a few years the movement was weakened by internal controversies over administration. These ended when O'Bryan left England in 1836 and settled in America.

On O'Bryan's departure, James Thorne, the first fully recognized minister, became its leader. Although reared as an ordinary farm lad, he proved to be a man of singular devotion and spiritual genius. He laid the foundations broadly in evangelism, finance, temperance and education, founding in the latter connection a middle-class school at Shebbear, at which generations of ministers' sons and numerous students for the ministry have been educated. James Thorne was five times president of the conference and 15 times secretary. He died in 1872. Another powerful leader was Frederick William Bourne, who served the Bible Christians as editor, missionary treasurer, book steward, and three times president of conference. (See METHODISM.)

BIBLE SOCIETIES, associations of a philanthropic character for translating and circulating the Holy Scriptures. The translation of the Bible has generally followed the expansion of the Church. By the 15th century, versions, more or less complete, existed in manuscript in about 20 languages. The invention of printing aided reproduction. Probably the first book printed in Europe from movable metal type was the Latin "Mazarin" Bible of c. 1456.

The Reformation greatly quickened men's interest in the Scriptures, so that notwithstanding the adverse attitude adopted by the Roman Church at and after the Council of Trent, the translation and circulation of the Bible made rapid progress. The pace was still further accelerated by the growth of modern Christian missions to non-Christian lands, for missionaries, especially those of Protestant Churches, have been among the most skilful translators and the most assiduous distributors of the Bible. Thus the earliest complete Arabic Bible was produced at Rome in 1671 by the Congregation for the Propagation of the Faith. The Tamil Bible, the earliest in any language of India, translated by two Danish Lutheran missionaries, Ziegenbalg and Schultze, was published 1715-28 with the assistance of the Society for Promoting Christian Knowledge. It is estimated that by 1800 the whole or

some part of the Bible had been printed in 71 languages, by 1900 in 567 and by 1928 in 856.

The Reformation also brought an element of philanthropy into circulation of the Scriptures. Thus, on the verso of the title page of the revised French Geneva Bible of 1588 there is a note that the expenses of the work, which was printed at the same time in three different forms to suit all kinds of persons, were liberally provided by certain good people not in order to gain profit for themselves but solely to serve God and His Church. Similarly, the Corporation for the Promoting and Propagating of the Gospel of Jesus Christ in New England (founded in 1649) bore the expense of printing both the New Testament and the whole Bible (Cambridge, Mass., 1663—the earliest Bible printed in America), which John Eliot, one of the Pilgrim Fathers, translated into “the language of the Massachusetts Indians” whom he evangelized. Again, The Society for Promoting Christian Knowledge (founded 1698) has done much to cheapen and multiply copies of the Scriptures, not only in English and Welsh, but in many foreign languages. In the present century, however, apart from its general literary activities, it has concentrated on the provision of Prayer Books and helps to Bible study in Asiatic and African languages.

The earliest noteworthy organization, formed for the specific purpose of circulating the Scriptures, was the Canstein Bible Institute, founded in 1710 at Halle, in Saxony, by Karl Hildebrand, Baron von Canstein (1667–1719), who was associated with some of the leaders of Pietism in Germany. He invented a method of printing whereby the institute could produce Bibles and Testaments in Luther's version at low cost and sell them cheaply. In 1722 editions of the Scriptures were also issued in Bohemian and Polish. In England various Christian organizations, which arose out of the evangelical movement in the 18th century, took part in the work. One such was founded in 1780 under the name of the Bible Society, but as its sphere was restricted to soldiers and seamen the title was afterwards changed to the Naval and Military Bible Society. The French Bible Society was instituted in 1792, but its designs were wrecked by the outbreak of the Revolution, and it was finally dissolved in 1803.

The British and Foreign Bible Society.—In 1804 was founded in London the British and Foreign Bible Society, the most important association of its kind. It originated in a proposal made to the committee of the Religious Tract Society, by the Rev. Thomas Charles of Bala, who found that his evangelistic and philanthropic labours in Wales were sorely hindered by the dearth of Welsh Bibles. His colleagues in the society united with other earnest evangelical leaders to establish a new body whose sole object would be “to encourage the wider circulation of the Holy Scriptures without note or comment.”

Supported by representative Christian leaders such as William Wilberforce and Henry Thornton, and with Lord Teignmouth as its first president, the new society made rapid progress. It spread throughout Great Britain, mainly by means of auxiliaries, *i.e.*, local societies affiliated but self-controlled, with subsidiary branches and associations. This system continues to flourish. In 1927–28 the society had 5,142 auxiliaries, branches and associations in England and Wales. There were also about 5,000 auxiliaries and branches outside the United Kingdom, mainly in the British dominions, and many of these carry on vigorous Bible distribution in their own localities, besides sending generous contributions to London. In 1904 the Canadian Bible Society was formed to act as an auxiliary to the parent society, with special responsibility for Bible work in Canada. Similarly, an Australian commonwealth council was established in 1924 and a New Zealand dominion council in the same year.

By one of its original laws the society could circulate no copies of the Scriptures in English except in King James' Version, but in 1901 this law was widened to include the Revised Version. In other languages the society has from the first successfully laboured to promote new and improved versions. By March 31, 1928, it had circulated versions in 608 languages, the complete Bible in 145, the New Testament in 146 more, and at least one complete book of the Bible in the remaining 317. In all but about 40 cases it was the

actual publisher. Translations or revisions in scores of languages are constantly being carried on by companies of scholars and representative missionaries under the society's auspices and often at its expense. New versions are made, wherever practicable, from the Hebrew or Greek text. The society's interdenominational character has commonly secured the acceptance of the same version by missions of different Churches working side by side.

Except under special circumstances the society does not encourage free distribution. It prefers to provide numerous editions at prices below the cost of production and within the reach of the poor, and makes further concessions to religious and philanthropic agencies. Its total issues from 1804 to 1928 were over 385 million. Of the 9,936,714 volumes issued in 1927–28, 3,790,275 were sent out from the London Bible House; 2,178,726 were in English; about 1,598,000 were circulated in Continental Europe; 442,000 in Africa; 1,075,000 in India and Ceylon; 3,640,300 in China; 986,000 in Japan and Korea; 473,000 in South America. The society owns 53 Bible houses and residences in the principal cities of the world, and rents depots in many others. It employs about 900 colporteurs. Its total income in 1927–28 was £417,295 and its expenditure £411,817.

In Scotland the Edinburgh Bible Society (1809), the Glasgow Bible Society (1812), and other Scottish auxiliaries, many of which had dissociated themselves from the British and Foreign Bible Society at the time of the Apocrypha controversy of 1826, were finally incorporated (1861) into the National Bible Society of Scotland, which since then has carried on vigorous work, especially in Europe, China, Central Africa and South America. Its total issues from 1861 to 1927 were 88,070,068 volumes. During the five years 1923–27 the average issues were 3,552,354 and the average income £39,299.

In Ireland the Hibernian Bible Society (originally known as the Dublin Bible Society) was founded in 1806, and with it were federated kindred Irish associations formed at Cork, Belfast, and other places. In 1927–28 the society had an income of £7,000, and issued 73,570 books, making a total, since its foundation, of 6,978,961. It sends an annual subsidy to aid the foreign work of the British and Foreign Bible Society.

In France the *Société biblique de Paris* was founded in 1818 with generous aid from the British and Foreign Bible Society. In 1927 its issues numbered 7,420. The *Société biblique de France*, which dates from 1864, issued, in 1927, 8,677 copies.

Central and Northern Europe.—The impulse which founded the British and Foreign Bible Society soon spread over Europe, and, notwithstanding the turmoils of the Napoleonic wars, kindred organizations on similar lines, promoted and subsidized by the British and Foreign Bible Society, quickly sprang up in Switzerland, Germany, Hungary, Holland, Poland, the countries round the Baltic, and Iceland. Many of these secured royal and aristocratic patronage and encouragement—the tsar of Russia, the kings of Prussia, Bavaria, Württemberg, Sweden and Denmark all lending their influence to the enterprise. The most noteworthy was that established in Russia. In 1812 Alexander I. sanctioned plans for a Bible society which was promptly inaugurated at St. Petersburg (now Leningrad) under the presidency of Prince Galitzin. Nobles and ministers of State, with the chief ecclesiastics of the Russian and other Churches, served on its committees. The society made rapid progress until 1823; in 1826 its operations were suspended by Nicholas I., who in 1828 sanctioned the establishment of a Protestant Bible society. From 1839 until the Revolution an agency of the British and Foreign Bible Society enjoyed special facilities in Russia, and at the beginning of the present century was circulating about 600,000 copies of the Scriptures annually in the empire.

Some of these societies are still at work. The circulation effected by the German Bible societies in 1927 was as follows: Württemberg Bible Institute (Stuttgart), 521,858; Prussian Bible Society (Berlin), 162,517; Berg Bible Society (Elberfeld), 191,474; Canstein Bible Institute (Halle), and smaller societies, 139,000.

The Netherlands Bible Society in 1927 circulated 173,897 vols., the Danish Bible Society 75,577, the Norwegian Bible Society 62,563, the Swedish Bible Society 87,056.

In Italy three Societies are circulating Scriptures with the approval of the Roman Church, the Pious Society of St. Jerome, the Society of Cardinal Ferrari and the Alba. It has been stated that about half-a-million copies of the St. Jerome Society's edition of the Gospels and Acts have been issued.

In America, the earliest Bible Society was founded at Philadelphia in Dec. 1808. It was followed in 1809 by the Connecticut (May), Massachusetts (July), Maine (August), New York (November) and New Jersey (December). Others quickly followed in succeeding years. Twenty-nine State and local Bible Societies organized in this early period have completed their century of service and are still at work. The Massachusetts Bible Society (State) with a circulation of 433,197 volumes, and the New York Bible Society (city) with a circulation of 892,706 volumes, accomplished the largest work in 1927.

The American Bible Society.—In 1816, a convention of delegates representing 31 State and local Societies met at New York and established the American Bible Society, with Elias Boudinot as president. Almost all kindred organizations in the States have gradually become connected with it as auxiliaries. At one time, they numbered over 2,000. Changed conditions and methods, by which contributions now come largely through denominational channels, have resulted in the disappearance of many of these auxiliaries. The original constitution of the society specified that its work should be "to encourage a wider circulation of the Holy Scriptures, without note or comment." This is still its sole object. In English, it circulates only the Authorized or King James and the Revised Versions. It is non-denominational with a lay board of managers. In 1927, 29 denominations appointed representatives on this Council.

Noteworthy versions of the Bible, such as those in Arabic, Armenian, Zulu, several dialects of Chinese, a number of American Indian, Philippine, Micronesian and African languages, have appeared under the auspices of the American Bible Society. It has shared jointly with the British and Foreign and the Scottish Bible Societies in Chinese, Japanese, Korean and Turkish Versions. Up to Dec. 1927, it had participated in the translation, printing or distribution of the Scriptures in 295 languages including various systems for the blind.

The purpose and work of the society is entirely missionary. It supplies the Scriptures without purpose of profit and largely through whole or part donations. It has 12 foreign agencies through which it works in Central and South America, the West Indies, the Levant, the Philippines, Siam, China and Japan. It has ten home agencies covering the United States, with headquarters at New York, Philadelphia, Washington, Richmond, Cincinnati, Chicago, Dallas, Denver and San Francisco; the agency among the coloured people also centring in New York. The appropriations for 1928 were \$1,345,426. During 1927, it issued 10,034,797 Bibles, Testaments and Portions, about half of which were for use in the United States and half for other countries. The total issues of the society since 1816 to the end of 1927 were 194,063,757 volumes.

The Gideon Society, organized in 1899 at Janesville, Wis., to carry the gospel message to commercial travellers and transients and to place Bibles in hotel guest rooms, had distributed by 1928 about 965,000 copies in the United States and Canada, as well as a number in China, Japan and Korea.

BIBLIOGRAPHY—Besides the published reports of the societies in question the following works may be mentioned: J. Owen, *History of the First Ten Years of the British and Foreign Bible Society*, 3 vols. (1816–20); G. Browne, *History of the Bible Society*, 2 vols. (1859); Bertram, *Geschichte der Consteinschen Bibelanstalt* (Halle, 1863); E. Pétavel, *La Bible en France* (Paris, 1864); O. Douen, *Histoire de la société biblique protestante de Paris* (Paris, 1868); G. Borrow, *The Bible in Spain* (London, 1849); W. Canton, *The History of the British and Foreign Bible Society*, 5 vols. (1904, foll.); J. Ballinger, *The Bible in Wales* (1906); H. O. Dwight, *Centennial History of American Bible Society*, 2 vols. (New York, 1916); T. H. Darlow and H. F. Moule, *Historical Catalogue of the Printed Editions of Holy Scripture*, 4 vols. (1903, foll.); R. Kilgour, *Gospel in Many Years* (1925).

BIBLIOGRAPHY. The word βιβλιογραφία was used in post-classical Greek for the writing of books, and as late as 1761, in Fenning's *English Dictionary*, a bibliographer is defined as "one

who writes or copies books." The transition from the meaning "a writing of books" to that of "a writing about books" had been made in France by 1763 when De Bure published his *Bibliographie instructive*. In England the new meaning was popularized by the Rev. T. F. Dibdin early in the 19th century, while Southey preferred the rival form *bibliology*, now disused. According to the objects pursued bibliography has two aspects. Of these the first looks to the author by whom a book was written, the time and place at which it was produced, the methods of its production, whether in ms. (see PALAEOGRAPHY) or in print (see TYPOGRAPHY), its decoration and illustration (see ILLUSTRATION), its binding (see BOOK-BINDING), its distribution by means of the book-trade and the price at which it was sold (see BOOK and BOOK-TRADE) and the obstacles imposed on its circulation (see CENSORSHIP). The second is concerned solely with its subject and value to those who read it. The two aspects overlap, but each has its own literature, for the publication of which separate societies are at work, and the use of some distinguishing terms, such as bibliography of the form of books and bibliography of their subjects, would save confusion.

Bibliography of the Form of Books.—The foundation of this is the careful examination and description of individual copies. Starting from the facts stated under the heading BOOK (*q.v.*) we may say that a standard description of any book which has both literary and typographical interest should comprise the following sections: (a) a literal transcript of the title-page (if it have one), also of the colophon (if it have one), and of any headings or other portions of the book serving to distinguish it from other editions or issues; (b) statements as to the size or form of the book, the gatherings or quires of which it is made up, with the total number of leaves, the measurement of the copy described and of the type-page, a note of the types in which different parts of the book are printed and a reference to any trustworthy information already in print; (c) a statement of the literary contents of the book and of the points at which they respectively begin; (d) a note giving any additional information which may be needed.

(a) In transcribing the title-page and other parts of the book the opening words should be given in full, any subsequent omissions being indicated by three dots placed close together. The end of a line should be indicated by an upright stroke, or in early books with the old long commas by double strokes to avoid confusion with these. It is a considerable gain to indicate to the eye the types in which the words are printed, *i.e.*, whether in roman, gothic letter or italic, and in each case whether in majuscules or minuscules. This, however, increases both the cost of printing and risk of error. In books before 1641, if upper-case letters are transliterated into lower the printer's own practice as to initial and medial *i* and *j*, *u* and *v* should be followed. Misprints in the original title should be reproduced either with a following [*sic*] or preferably with a footnote to the description.

(b) The "size" of a book was originally a technical expression for the relation of the individual leaves to the sheet of paper of which they formed a part. A book in-folio meant one in which the paper had been folded once, so that each sheet had made two leaves. In a book in-quarto each sheet had been folded twice so as to make four leaves. In an octavo another fold had produced eight leaves, and so on for books in 16mo, 32mo and 64mo. For books in twelves, twenty-fours, etc., the paper had at some stage to be folded in three instead of two, and their form differed according to the way in which this had been done. The size of old books can mostly be ascertained by noting whether the thicker white lines visible in the paper when held up to the light run perpendicularly or horizontally. These wire-lines (so called from being made by the wires of the trays in which paper was made) run perpendicularly in folios and octavos, horizontally in quartos and sextodecimos. In tall duodecimos they are perpendicular, in "dumpy" ones horizontal. In small quartos and the lesser sizes only one sheet was usually sewn at a time, so that the number of leaves corresponds with the name of the size; in folios and large quartos, to reduce the amount of sewing, one or more additional sheets were placed inside the first, so that the earliest folios often have ten leaves in the quire, and the earliest large quartos eight.

When a ms. or early printed book was being prepared for binding it was usual for the order in which the quires or gatherings were to be arranged to be indicated by signing them with the letters of the alphabet in their order, the alphabet generally used being the Latin, in which I stands for both I and J; V for both U and V, and there is no W. If more than 23 letters were needed the contractions for *et*, *con*, *rum* and (less often) that for *us*, were used as additional signs, and for large books minuscules were used as well as majuscules, and the letters were doubled. In 1472 printed signatures are found and they are still in use. If the quires or gatherings in the book to be described are signed in print, the signatures used should be quoted without brackets. If they are not signed, the order of the gatherings should be noted by the letters of the alphabet in square brackets. In each case the number of leaves in each gathering should be shown by index-figures. Thus, six gatherings of eight leaves followed by one of four should be represented by the symbols A-I⁸ G⁴. The "make-up" of an old book in original binding is usually sufficiently shown by the strings in the middle of each quire. In re-bound copies of old folios and quartos the best guide to it is to note the sequence of the watermarks, i.e., the devices with which the papermaker as a rule marked each sheet (see PAPER). In a folio book one of every pair of leaves should have a watermark in the middle of the paper. In a quarto some pairs of leaves will have no watermark; in others it will be found divided by the fold of the paper.

After the size and sequence of the gatherings has been stated the total number of leaves should be noted, with a mention of any numeration of them given in the book. Errors in the printed numeration of the leaves of old books are common, and it is seldom necessary to point them out in detail. Printed leaf numeration is found as early as 1470, and became common about ten years later. Printed pagination did not become common till nearly the middle of the 16th century.

The foregoing details are all directed to showing which leaves of a book would be printed by the same pull of the press, how it was made up for binding, and how imperfections in any copy may be detected. They give little or no indication of the dimensions of the book, and it is therefore necessary to add the measurements in inches or millimetres of a page of an uncut copy. In old books uncut copies are not easily found, and it is useful instead of this to give the measurement in millimetres of the printed portion of the page (technically called the "type-page"), from which, if the habits of the printer are known, the size of an uncut copy can usually be deduced. To this is added a statement of the number of lines in the page measured. The character of the type (roman, gothic or italic) is next mentioned, and in the case of 15th-century books the measurement of 20 lines of type. Finally, a reference to any authoritative description already printed completes this portion of the entry. Thus the description of the collation of the first-dated book printed at Augsburg, the *Meditationes* of S. Bonaventura, printed by Günther Zainer in 1468, should read: Folio, [a¹⁰, b-d⁸, e-g¹⁰, h⁸] 72 leaves. Type-page 205×122 mm.; 35 lines. Type 1 (gothic letter, 117 mm.). Hain *3557.

(c) While many books, especially early ones, contain little or nothing beyond the bare text of a well-known work, others are well provided, not only with commentaries which are almost sure to be mentioned on the title-page, or in the colophon (which the editor himself often wrote), but also with dedicatory letters, prefaces, complimentary verses, indexes and other accessories, the presence of which it is desirable to indicate. In these cases it is often convenient to show the entire contents of the book in the order in which they occur, noting the leaves or pages on which each begins. Thus in the first edition (1590) of the first three books of Spenser's *Faerie Queene*, the literary contents, their order and the space they occupy can be concisely noted by taking the successive gatherings according to their signatures and showing what comes on each page. Thus: A₁, recto, title; verso, dedication, "To the Most Mightie and Magnificent Emperesse Elizabeth"; A₂-Oo₈, text of books i.-iii.; Pp₁, letter dated Jan. 23, 1589 [1590] to Sir Walter Raleigh expounding the intention of the work; Pp₂ verso, commendatory verses signed W. R[aleigh],

Hob-ynoll (Gabriel Harvey), R.S., H.B., W.L. and Ignoto; Pp₁₋₄, complimentary sonnets severally inscribed to Sir C. Hatton, the earls of Essex, Oxford, Northumberland and Ormond, Lord Ch. Howard, Lord Grey of Wilton and Sir W. Raleigh, and to Lady Carew and to the Ladies in the Court; and "Faults escaped in the print"; Qq₁₋₄, 15 other sonnets.

The Results of Collation.—When books have been examined with the care needed to produce descriptions of this kind they fall into their places in the general history of printing or the output of an individual press, and if their characteristics are inconsistent with the place or date claimed for them their pretensions can be exposed, as in the case of the Lyonnese counterfeits of the octavo editions of the classics printed by Aldus at Venice, the numerous unauthorized editions of works by Luther, professing to be printed at Wittenberg, or again the numerous controversial books printed in England in the 16th century purporting to have been produced in German towns or, with pleasant humour, "at Rome before the Castle of S. Angel at the Sign of S. Peter." In the same way the not very numerous cases of incorrect dating in early books when placed side by side with other books of the period can gradually be transferred to the earlier or later groups into which they fit, and the wrong dates are mostly found to be due either (i.) to simple misprints, as in the omission of an *x* in the date Mccccxviij in the first book printed at Oxford; (ii.) to the use in reprints (mostly in legal books, 1560-80) of the date of the first edition to indicate that the text was unaltered; (iii.) to a desire to help surreptitious new editions to escape notice, as in the Geneva Bibles printed in Holland for importation into England after 1617, which were dated 1599, or the later reprints of Shakespeare's *Venus and Adonis* dated 1602.

Collation helps also to determine the order of undated editions, since in reprints a printer had opportunities, which he seldom failed to use, of saving space here and there and so reducing his bills for paper and presswork, and could also set up the successive sheets of preliminaries and text consecutively in their order instead of printing text first and preliminaries after as was usual in first editions. It may even discover evidence of authorship, as when Skeat found that the initial letters of successive chapters of the *Testament of Love* made up a sentence, and Henry Bradley by correcting a wrong arrangement of the sheets showed that the sentence implied the authorship of the book by Thomas Usk, and thus relieved Chaucer, to whom it had most injuriously been attributed, of the burden of it. Collation also brings to light irregularities in the sequence of the sheets of which a book is composed, which can be traced to after-thoughts of the publisher or author, necessitating the insertion of additional leaves and sometimes also the excision of others already printed. Thus, as originally printed, the first sheet of the 1609 quarto of Shakespeare's *Troilus and Cressida* consisted of a title-page, beginning "The Historie of Troylus and Cresseida. As it was acted by the Kings Maiesties seruants at the Globe," and three leaves of text. The title-leaf was subsequently cut out and two leaves (a half-sheet) substituted, the first bearing a new title, the second (with signature C₁) a preface stating that this was "a new play, never stal'd with the Stage." Literary students had long disputed as to which of these variants was the earlier, but the bibliographical evidence is decisive. So again, variations between different copies of the first edition of Herrick's *Hesperides* (1648), which had puzzled his editors, are easily explained as due to the presence of three such cancels. In the 18th century resort to cancels was extraordinarily frequent, and it still occurs. Owing to the extreme slowness of the presswork of the early printers there were more opportunities in their days for making corrections and alterations while a book was still passing through the press than there are now. Thus the first printer at Mainz can be shown to have increased the size of the edition of the first great Latin Bible after a start had been made, so that a few of the leaves are found in two states owing to additional copies having been printed after the type of the first setting had been dispersed, and of the extant copies of the first quartos of Shakespeare's *Richard II.* (1597) and *King Lear* (1608) some have corrected readings on certain leaves which in others are left uncorrected.

On the other hand the leather inking-balls used by the pressmen sometimes caught up one or more pieces of type from the forme and if these were replaced wrongly the sheets subsequently printed would have incorrect readings instead of correct ones, and some of the small variations noticed in different copies of the First Folio Shakespeare and again in the first edition of Milton's *Paradise Lost* have been ascribed to this cause. All the sheets, correct or incorrect, would be used indiscriminately when the book came to be bound, and thus it has been said with some approach to truth that no two copies of an Elizabethan book are absolutely identical. These minor variations thus only constitute different "states" of the leaves or sheets on which they occur, while the substitution of a different title-page, as in the 1609 *Troilus* mentioned above, constitutes a different "issue," both "states" and "issues" being parts of one and the same "edition."

Enumeration and Arrangement.—If every book bore the true name of its author, the correct date and place of its publication, and the names of its printer and publisher, and no mishaps occurred in the course of printing and publication, it would still remain the task of what is here called formal bibliography to collect information as to all the books written by a certain author, or printed by a certain printer, or published in a certain city or country, and arrange them in chronological order under the names of the author, or the printer, or the city or country, according to the plan undertaken. The ideal to which bibliography of this kind is directed is the compilation for each country of a national register of its literature in the form of annals of publication with indexes of authors and (in so far as they are of interest) of printers and publishers, illustrators and any other persons connected with the book, so that under the name of each all their contributions would be shown. The old ideal was directed to a universal register of books, and for those published in the 15th century the zeal of students of early printing has provided the material for an almost exhaustive list, the *Gesamtkatalog der Wiegendrucke* (see INCUNABULA). Of those printed in the years 1501–36 there is a tentative enumeration in the continuation of Panzer's *Annales Typographici* (1803), and materials are gradually being collected for improving and extending this. But the projects once formed for a universal bibliography have dwindled in proportion as the output of the press has increased, and the nearest approaches to such a work are the printed catalogue of the library of the British Museum, and that of the Bibliothèque Nationale at Paris, now in progress. When a universal bibliography was recognized as an impossibility patriotism suggested the compilation of national bibliographies, and the *Bibliotheca Britannica* of Robert Watt (Edinburgh, 1824) remains an extraordinary example of what the zeal of a single man could accomplish in this direction. Quérard's *La France littéraire* (1827–39), while it gives fuller titles, is much less comprehensive, embracing mainly books of the 18th and early 19th centuries, and only a selection of these. In the works of Heinsius (*Allgemeines Bucherlexikon*, 1700–1815, Leipzig, 1812–17) and Kayser (*Bücherlexikon*, 1750, etc., Leipzig, 1834, etc.) Germany possesses a fine record of her output of books during the last two centuries, and since the organization of the book-trade contemporary lists of books, with *résumés* and indexes issued at intervals, exist for most European countries. For English books up to the close of the year 1640, with the aid of catalogues previously published by the British Museum, the Cambridge university library, and other institutions, a *Short-title Catalogue* was compiled by members of the Bibliographical Society and issued in 1926. This comprises over 26,000 entries and gives references to libraries in which copies are preserved.

Subject-Bibliography.—In the 18th and early 19th centuries there was a tendency, especially among French writers, to impose upon bibliography the task of indicating the exact place which every book published should occupy in a logical classification of all literature based on a previous classification of all knowledge. It came to be recognized that the classification of human knowledge is a task for philosophers and men of science, and that, for example, to make a good bibliography of chemistry requires a

knowledge of chemistry and of its history quite extrinsic to bibliography itself, which can only at most suggest certain general principles of arrangement, and point out to some extent how they may be applied. The essential requisite is a clear idea of the use to which the bibliography is to be put. If its chief object be to give detailed information about individual books, a strictly alphabetical arrangement "by authors and titles" (i.e., by the names of authors in their alphabetical order and the titles of their books in alphabetical sequence under the names) will be the most useful. If it is desired to illustrate the history and development of a subject, or the literary biography of an author, the books should be entered chronologically. If direction in reading is to be given, this can best be offered by a subject-index, in which the subjects are arranged alphabetically for speedy reference and the books chronologically under the subject, so that the newest are always at the end. Lastly, if the object is to show how far the whole field has been covered and what gaps remain to be filled, a class catalogue arranged according to what are considered the logical subdivisions of the subject has its advantages. It is important, however, to remember that, if the bulk of the bibliography is very large, a principle of arrangement which would be clear and useful on a small scale may be lost in the quantity of pages over which it extends. In 1886 a great impetus was given to subject-bibliography by the publication by the British Museum of a *Subject-Index of the Modern Works* added to its library since 1880, compiled by Mr. G. K. Fortescue, under whose editorship an enlarged index covering the 20 years 1881 to 1900 was subsequently published, while supplementary indexes have since been issued quinquennially, bringing the total number of books registered under subjects to nearly half a million. In 1895 the Institut internationale de Bibliographie at Brussels issued its first bulletin, and the international character of modern science has gradually led to the revival of old ideals in less ambitious forms. Nearly 20 years earlier (in 1876) Mr. Melvil Dewey, while helping to found the American Library Association and American Metric Bureau, outlined his decimal system for the classification of books, and this, as he gradually worked it out, was widely adopted by librarians not only in the United States, but in England and elsewhere despite much criticism and the competition of rival systems. With Dewey's permission the Institut internationale de Bibliographie, in a *Manuel de la Classification*, amplified his scheme so as to make it available for indexing literature on the widest scale, and in 1927 a British Society for International Bibliography was founded as a branch of the Institut, in order "to promote the study of bibliographical methods and of the classification of information, to secure international unity of bibliographical procedure and classification and to foster the formation of comprehensive and specialist bibliographies of recorded information." In this way the ambitious ideals of subject-bibliography are in process of being realized, not by bibliographers parcelling out knowledge into pigeon-holes but by the workers in each subject helping to form a classification which will answer to their own peculiar needs.

The only competent treatise on the bibliography of the form of books is *An Introduction to Bibliography for Literary Students*, by R. B. McKerrow (1927), based on a paper entitled *Notes on Bibliographical Evidence for Literary Students and Editors of English Works of the 16th and 17th Centuries*, read before the Bibliographical Society in 1913. See also F. Madan's paper *On Method in Bibliography*, in vol. i. of the Society's *Transactions* (1893), and *Some Points in Bibliographical Descriptions*, by A. W. Pollard and W. W. Greg, and a memorandum on *Degrassive Bibliography*, by F. Madan in vol. ix. (1909). Subject-bibliographies will be found listed at the beginning of the entries of books on the subjects with which they are concerned in the successive volumes of the British Museum's *Subject-Index of the Modern Works added to the Library*. For books published before its issue W. P. Courtney's *A Register of National Bibliography, with a selection of the chief bibliographical works and articles printed in other countries* (1905) is still useful. (A. W. P.)

BIBLIOMANCY, a form of divination (*q.v.*) by means of the Bible or other books. The method employed is to open the Bible haphazard and be guided by the first verse which catches the eye. Among the Greeks and Romans the practice was known under the name of *sortes Homericae* and *sortes Virgilianae*, the books consulted being respectively those of Homer and Virgil.

BIBRACTE, an ancient Gaulish hill-top town, 2,500ft. above sea-level, the modern Mt. Beuvray, near Autun, in France. Excavation has revealed an area of 330 acres, girt with a stone and wood rampart 3m. long, and containing the remains of dwelling-houses, a temple of Bibractis, and workshops of iron and bronze workers and enamellers. It was the capital of the Aedui in the time of Julius Caesar. Later on Augustus removed the inhabitants to his new town Augustodunum (Autun), to destroy the free native traditions. Another far more obscure town in Gaul, near Reims, also bore the name.

See J. G. Bulliot, *Fouilles de Beuvray* (Autun, 1899); J. Déchelette, *L'Oppidum de Bibracte* (1903); also references, s.v. AEDUI.

Battle of Bibracte.—This battle was the climax of Julius Caesar's first campaign in Gaul 58 B.C. Before he could contemplate the expansion of Rome's dominion he found that he had to deal with an imminent threat to the security of the existing province. For the Helvetii, assembling around Lake Geneva were about to begin a tribal migration into the fertile plains of Gaul. By negotiations, more diplomatic than sincere, Caesar gained time to block their path across the Rhône. The delay enabled him to return to Cisalpine Gaul and raise two new legions, concentrate three others, and then march back across the Alps to reinforce the solitary Tenth Legion on the Rhône. The Helvetii meanwhile had pursued their leisurely course along the north bank of the Rhône. Caesar caught them in the act of crossing the Arar (modern Saône) just north of its junction with the Rhône near modern Lyon, and inflicted a sharp check. The Helvetii now turned northwards, followed cautiously by Caesar until, embarrassed by shortage of supplies, he decided to press on ahead of them to Bibracte (near modern Autun). His difficulty encouraged the Helvetii to move against him, and their harassing of his march became so unpleasant that he turned at bay on a hill before reaching Bibracte. Posting the two untried legions and the auxiliaries with the baggage on the crest, he formed the remainder in three lines. The Roman javelin (*pilum*) throwing was so effective that it did much to break up the solidity of the assault, and enabled the legionaries to press the enemy steadily back in the close quarter combat. But as the legions followed up the retirement of the Helvetii they laid bare their own rear. The opportunity to fall upon this was seized by a large body of the allied Boii and Tulungi who had been guarding the wagon-park of the Helvetii. To meet the danger Caesar turned his third line about and after a stern struggle repulsed the double attack now launched. The success was eventually completed by the capture of the wagon-park.

BIBULUS, a surname of the Roman gens Calpurnia. The best known of those who bore it was Marcus Calpurnius Bibulus the persistent enemy of Caesar, with whom he was consul, 59 B.C. He was the candidate of the aristocratic party and his election was secured by bribery (Suetonius, *Caesar*, 9). He made an attempt to oppose the agrarian law introduced by Caesar but was overpowered. He then shut himself up in his own house during the remaining eight months of his consulship, taking no part in public business beyond issuing edicts against Caesar's proceedings. When the relations of Caesar and Pompey became strained, Bibulus supported Pompey (Plutarch, *Cato Minor*, 41) and joined in proposing his election as sole consul (52 B.C.). Next year he went to Syria as proconsul. In 49 Pompey gave him command of his fleet in the Ionian Sea, but he proved unsuccessful and died soon afterwards (48) of fatigue and mortification (Caesar, *Bell. Civ.*, iii. 5-18; Dio Cassius, xli 48). His youngest son, Lucius Calpurnius Bibulus, surrendered to Antony soon after the battle of Philippi and was by him appointed to the command of his fleet. He died (about 32) while governor of Syria. He wrote a short memoir of his step-father Brutus, which was used by Plutarch (Appian, *B C.*, iv. 136; Plutarch, *Brutus*, 13. 23).

BICARBONATE, in chemistry, an acid carbonate, a salt in which one only of the two hydrogen atoms in the molecule of carbonic acid has been replaced by metal. Na_2CO_3 is the formula of normal sodium carbonate, washing soda; NaHCO_3 is that of sodium bicarbonate, or baking soda. (See ANTACID; CARBON; and SODIUM.)

BICE, a term erroneously applied to particular shades of green or blue pigments from the French terms *vert bis* and *azur bis*, dark green or blue. These colours are generally prepared from basic copper carbonates, but sometimes from ultramarine and other pigments.

BICEPS, the name given to one of the muscles of the upper arm, from which the latter derives its rounded appearance in front. It has two heads or origins, the shorter attached to the coracoid process of the scapula, the longer to the edge of the glenoid cavity. The two heads unite to form a central portion or belly, which ends in a tendon, the distal end of which is inserted on the radius. The muscle on contraction has the effect of flexing the forearm and assisting in the supination of the hand. See MUSCLES and MUSCULAR SYSTEM.

BICESTER (bis'tyr), urban district of Oxfordshire, England, 12m. N.N.E. of Oxford by the L.M.S.R.; pop. (1921) 3,739. It lies in a pastoral country on the northern edge of the open plain of Ot Moor. The termination *cester*, commonly indicating Roman origin, does not appear to do so here, and is perhaps copied from Alchester and Chesterton, a village two miles west of Bicester, where a Roman site has been recognized at the junction of roads from the south (Dorchester) and from the west, north-east and east. There are records of the settlement (Berncestre, Burencestre, Bissiter) from the time of Domesday. In 1182 Gilbert Basset founded an Augustinian priory which was the centre of industrial life until its dissolution in 1538. Richard II granted a fair and a Monday market, and in 1440 an additional market was granted, to be held in that part of the town called Bury-End, from this date known as Market-End. In the 16th century the cattle market was specially famous.

The church of St. Eadburg contains examples of Norman and each succeeding style. There are scanty remains of the Augustinian priory. Bicester never possessed any manufactures of importance. It has considerable agricultural trade and is famous as a hunting centre. It lies on the G.W.R. line from London to Birmingham.

BICHAT, MARIE FRANÇOIS XAVIER (1771-1802), French anatomist and physiologist, was born at Thoirette (Jura) on Nov. 14, 1771, the son of a physician. He studied anatomy and surgery under M. A. Petit (1766-1811), chief surgeon to the Hôtel-Dieu at Lyons. The revolutionary disturbances drove him to Paris in 1793. He there became a pupil and then assistant of P. J. Desault, who died in 1795. He completed the fourth volume of Desault's *Journal de Chirurgie*, to which he added a biographical memoir of its author. He then wrote the *Oeuvres chirurgicales de Desault, ou tableau de sa doctrine, et de sa pratique dans le traitement des maladies externes* (1798-99), in which, although he professes only to set forth the ideas of another, he develops them with the clearness of one who is a master of the subject. In 1797 he began a course of anatomical demonstrations, and then began to lecture on operative surgery and physiology. His *Anatomie générale* (1801), contains the fruits of his most profound and original researches. His *Anatomie descriptive* (1801-03), in which the organs were arranged according to his peculiar classification of their functions, was completed by his pupils, M. F. R. Buisson (1776-1805) and P. J. Roux (1780-1854).

Before Bichat had attained the age of 28 he was appointed physician to the Hôtel-Dieu, a situation which opened an immense field to his ardent spirit of enquiry. He engaged in a series of examinations, with a view to ascertain the changes induced in the various organs by disease, and in less than six months he had opened about 600 bodies. A fall from a staircase at the Hôtel-Dieu resulted in a fever, and he died on July 22, 1802. His bust, together with that of Desault, was placed in the Hôtel-Dieu by order of Napoleon.

BICHROMATES: see CHROMATES and DICHROMATES

BICKERSTAFFE, ISAAC (c. 1735-c. 1812), British dramatist. He was the author of many plays and burlesque farces interspersed with songs, produced between 1760 and 1771. The best-known are *Maid of the Mill* (founded on Richardson's *Pamela*), *The Padlock*, *He Would if he Could*, *Love in a Village*, *The Hypocrite*, and *The Captive*. In 1772 Bickerstaffe, suspected

of a capital offence, fled to the Continent. The exact date of his death is unknown, but it is recorded that he was living in abject misery in 1812.

A full account of his dramatic productions is given in *Biographia Dramatica*, ed. Stephen Jones (1812).

BICKERSTETH, EDWARD (1786–1850), English hymn writer, was one of the secretaries of the Church Missionary Society, from 1816 to 1830, and rector of Watton, Herts., from 1830 to his death. His *Christian Psalmody* (London, 1833), a collection of over 700 hymns, went through 59 editions in seven years, and formed the basis of the *Hymnal Companion* (London 1870), compiled by his son, E. H. Bickersteth, bishop of Exeter (1885–90).

EDWARD BICKERSTETH (1814–1892), dean of Lichfield, was his nephew, and EDWARD BICKERSTETH (1850–1897), bishop of South Tokyo, his grandson.

BICKNELL, a city of Knox county, Indiana, U.S.A., on the Pennsylvania railroad, 15m. N.E. of Vincennes, in a coal-mining and agricultural region. The population was 2,794 in 1910; 7,635 in 1920.

BICYCLE, a light vehicle formed of two wheels mounted in single line in a simple frame of steel tubes, which is equipped with handles, pedals attached to cranks and a saddle. The rider sits on the saddle, grasps the handlebars, and turns the cranks with his feet by means of the pedals, thus imparting motion to the rear wheel through a chain driven over toothed rings or sprockets.

After several decades of intensive research, development and improvement, bicycles have become the most numerous class of vehicle on the roads of England, France, Germany, Holland, Italy, Belgium and Denmark, while they are very widely used in North America and elsewhere. The bicycle is easily mastered, and can be ridden with very little effort at ten to twelve miles per hour by any normal person. Being easy to house and carry, inexpensive to purchase and maintain, and simple in construction, it is a valuable instrument of self-transport, and it provides pleasant recreation and exercise even while being used for purposes of utility. Cycle-touring is most widely practised in England, but has a large and increasing number of followers in Germany, France and other European countries. Bicycles are also widely used for racing in France, Germany, Belgium, and to a lesser extent in England and the United States (see CYCLING).

The oldest existing trace of the cult of self-propulsion occurs in a stained-glass picture in a church window at Stoke Poges, Buckinghamshire, England. This depicts a figure seated upon a wheeled instrument and apparently using the feet against the ground to propel itself. That, at any rate, is the interpretation placed upon the picture by all authorities. The next development was a ponderous four-wheeled carriage propelled by a footman, whose unenviable task it was to depress two heavy timber levers alternately, thus turning the rear wheels by a crude rack-and-pinion device. This is referred to in contemporary English literature from 1769 onwards, and an improved form was exhibited in Paris and actually paraded before the court of Louis XVI. and Marie Antoinette at Versailles in 1779.

The Hobby-horse, 1816.—

Nothing was gained by such contrivances, for the best speed, even with two drivers, was barely equal to walking pace, and there is no further trace of a velocipede in history until 1816, when an important development occurred in Paris. This was the introduction of the hobby-horse, a simple device consisting of two wheels and a cross-bar, upon which the rider sat while he propelled himself with his feet against the ground. Invented by M. Niepce, a pioneer of photography, the celeripede, as it was called, quickly gained favour. In 1818 it was further improved by Baron de Saverbrun, who is said to have performed some remarkable feats of speed upon it; and in the same year it came to London, where many models were made by Dennis Johnson of Long Acre. The price was high and the machine was not

within the reach of ordinary folk; thus it became known as the dandy-horse, and was used by the prince regent, among others.

The craze—for such it undoubtedly was—spread to America and lasted for a year or two in the Old and the New World, until the natural crudities of the device killed it, and nothing more is recorded until 1840, when the first real bicycle was made in Scotland by Kirkpatrick MacMillan, of Dumfries. This pioneer took a dandy-horse, added cranks, pedals and driving rods to it, built a comfortable seat, elaborate armrests, handlebars, etc., and rode the machine for many years, once being prosecuted and fined for “furious driving” on the roads. In 1846 Gavin Dalzell improved MacMillan’s machine, and the Dalzell became widely known, many specimens being made. These two men are the real pioneers of the bicycle.

FIG. 2.—THE VELOCIPEDE, OR “BONESHAKER,” c. 1865

This was the first crank driven bicycle, and large numbers were sold in France, England and America

After them no important event in bicycle history took place for nearly 20 years. It was during this period that isolated examples of velocipedes were built in remote parts of England and other countries, and most of the apparently baseless claims to have “built the first bicycle” relate to this era.

But hitherto there had been no bicycle with rotary cranks. That came in 1865, and was the invention of Pierre Lallement, a workman employed by M. Michaux, of 29, Avenue Montaigne, Paris, an address which is given here in full because it was the first shop at which bicycles were made and sold in an ordinary commercial way. Lallement sold the patent to Michaux and then emigrated to the U.S.A., where he propagated the same idea. Meanwhile Michaux did good business with the velocipede at 200 francs each. At about the same time an extraordinary wave of interest in velocipedes swept over England, and inventions and freak constructions were numerous. The industry in England was begun on regular lines by the Coventry Sewing Machine Company, who, in order to fulfil an order placed by their Paris agent for 500 machines of the Michaux type, reconstructed their business in 1868 under the name of the Coventry Machinists’ Co. Ltd. Afterwards it became the Swift Cycle Co. Ltd. However, when only a few of the bicycles had been despatched to Paris, the Franco-Prussian war broke out, and this mischance actually established the trade in England, for it compelled the Coventry Machinists’ Co. to find a home market for the remainder of the 500 machines ordered for Paris.

These Michaux-pattern bicycles belong to the class which came to be known as “boneshakers.” They had two wheels of nearly equal size (the front being larger), and the driving-crank and pedals were fitted to the axle of the front wheel. With heavy wooden wheels, thick iron tyres and a massive iron backbone, these machines were extremely heavy, and they vibrated in a terrifying manner over the rough roads. This vibration and weight caused intense fatigue to the rider, but despite this the new vehicle gained in popularity, for it opened up new possibilities.

The Tall “Ordinary.”—Then some important improvements came, as more firms began to manufacture boneshakers, and new ideas were brought into the industry. The heavy wooden wheels gave place to lighter ones of metal, with thin wire spokes set at a tangent to the centre. Solid rubber tyres were cemented to the rims, and the increased speed potentialities were utilized by enlarging the front or driven wheel, so that a higher ratio of gearing was employed or, in other words, a greater distance was travelled with each revolution of the cranks. This tendency continued, and the front wheels grew from 30in. to 40, 48, 52, 60 and even 64in. in diameter, while the rear wheel shrank to 12in. or less. This was the type known as the “ordinary,” and it remained in vogue for 20 years, during which time bicycling became a firmly-established pastime in England, America, France and other countries. Ball-bearings were introduced in 1877.

FROM “THE DAILY MIRROR”

FIG. 1.—THE FIRST BICYCLE, MADE IN SCOTLAND c. 1839

The "ordinary" bicycle naturally gave a great advantage to tall men, who could sit a higher wheel, and thus command a larger gear and travel at a faster speed for the same pedalling rate. If lacking in inches, however, the shorter men were not without brains, and several schemes were devised to place them on an equality with their taller brethren. One of these was the "geared ordinary," in which the cranks and pedals were mounted considerably below the front axle, to which power was transmitted by a chain running over sprockets. Short riders began to turn in increasing numbers, however, to the tricycle, or three-wheeled cycle, which, while the "ordinary" bicycle remained current, gained a popularity out of all proportion to its vogue in more modern times.

The "Safety."—The "safety," or low bicycle familiar to moderns, was made possible by geared-up transmission; that is, the pedals and cranks drove a large sprocket, from which motion was imparted by a chain to a smaller sprocket on the hub of the rear or driven wheel. Thus, although the rear wheel was much smaller than the driven wheel of an "ordinary," the drive could be geared up so that the bicycle's speed in relation to the pedalling strokes was as fast or faster than that of an "ordinary." Curiously enough, the custom has survived of describing a bicycle's "gear" by comparing it with an "ordinary"; for example, a bicycle geared to 65 travels as far, with one revolution of the cranks, as would an "ordinary" bicycle with a 65-in. front wheel.

First invented by H. J. Lawson in 1876, the "safety" rear-driven bicycle was first marketed in a practicable form by Messrs. Starley and Sutton, of the Rover Company, in 1885, and from that time the "ordinary" was doomed, although it lingered until the early 'nineties, and was brought to a really excellent state of precision and lightness (the best racing "ordinaries" weighing only 19 lb.). The following figures tell their own story, however. They represent the percentage of the different types at the two great cycle exhibitions in England during the critical years:—

TYPE.	1889.	1891.	1893.
Ordinary	11.5	3.3	
Rear-driven safety	53.6	86.7	84.6
Single tricycle	22.1	7.7	5.3

The greatest revolution in bicycle history was the introduction of the pneumatic rubber tyre in 1889 by John Boyd Dunlop, of Belfast. Although received with scepticism at first, it was quickly appreciated at its true worth, riders finding that it gave an enormous increase of comfort and speed. In an attempt to stem its advance, makers introduced a cushion-tyre which enjoyed a brief vogue, but soon the air-tyre carried all before it. The following percentages at the English exhibitions are significant:—

TYRE.	1890.	1891.	1891 (later).	1892.	1893.	1894.
Solid	98.6	29.1	16.6	4.0	3.1	0.4
Cushion06	54.2	32.5	14.9	14.7	3.3
Pneumatic	1.2	14.0	39.7	65.5	69.3	89.5

The combination of "safety" bicycle and pneumatic tyre placed the bicycle on an unassailable foundation, and since that date its use has rapidly spread. The "safety" bicycle of 1893 was the modern bicycle in general outline, although there have been many important alterations in detail, as will be shown. Free wheels, which enabled the bicycle to coast or overrun the driving mechanism, were introduced in 1894, and variable gears in 1899.

The bicycle-making industry in the United States was started in 1877 when Col. Albert A. Pope of Boston, Mass., organized the Pope Mfg. Company. The new industry went through about the same changes in models and types, as in England—the Ordinary,

the Geared Ordinary, a lever propelled machine called the "Star" with a large driving wheel at the rear and a small steering wheel in front, solid and cushion tyre safety, and in 1890 finally the pneumatic tyre safety. The industry had a period of great prosperity in 1892-94, when it established a sound export business. This was assisted by the fact that when, just afterwards, a similar boom began in England, the demand exceeded the supply, and American machines were eagerly snapped up. The English boom was a very important epoch in cycle history. Bicycling became fashionable among the wealthy classes, prices soared and many companies were floated and refloated. Later came the inevitable slump, after which the English factories were reorganized and learnt to produce a reliable bicycle at a very moderate price.

The Modern Bicycle.—In its modern form the bicycle is a remarkable piece of engineering, for it carries a load up to ten times its own weight, and is propelled over all kinds of surfaces with very few mishaps. The two wheels run in perfect alignment, as also do the two transmission sprockets, while all bearings are truly parallel to each other and to the direction of travel. Bicycles weigh from 15 to 35 lb., the lightest being suitable only for racing on specially-prepared tracks. The constructional details are as follows:—

Frame.—This gains its great strength from its triangulated design, by which there is no unsupported beam except the front forks. If the latter were braced or supported, they would impart all road shocks direct to the rider, unless a satisfactory springing arrangement was evolved—a difficult problem. As it is, the forks are curved so that they spring slightly, while the section of weldless steel tubing used is round, oval or D-shaped (with the flat side facing inwards). It is usual to draw the tubing in a thickness which tapers from 21 gauge at the hub end to 18 gauge at the top. This prevents the concentration of strain at the top end. The fork crown (at the top of the forks) is fixed to the steering column, which turns freely in two ball bearings in the head tube, and in which is set the handlebar. The slope or steering angle is the cause of a bicycle running naturally in a straight line, because any movement of the wheel out of the straight tends to raise the bicycle slightly; therefore the weight of bicycle and rider discourages any such deflection of the front wheel except when directed by the rider, and a truly-made bicycle will run in a straight line so long as it is upright, except when the front wheel is forced aside by stones, etc. From this point of view even more steering angle, or "rake," would be permissible, but the desirability of curving the front forks, and also the need for avoiding breakage, keeps the angle within moderate limits.

The steering column is a very important part, and ought to be of 13-gauge thickness at the bottom end, and it is usual to make the gauge to taper to 16 at the top end, where threads are cut to accommodate the head ball bearing cup, the locking-rings, etc. Breakages usually result from the negligence of makers who, finding the column too long for the particular bicycle they are making, shorten it by cutting away the valuable thickened part at the bottom, to avoid the trouble of making new threads which would be necessitated were they to shorten the column at the top. For steering columns and forks a steel with a minimum carbon content of .32% is recommended.

Main Frame Tubes.—In the better quality bicycles these are butted or thickened at each end, where the gauge is usually 19, as against 22 in the centre. Mild steel, i.e., steel with a carbon content of .35%, is generally used, and it has been found that the double-butt tubing is much stronger than a plain tubing of 20 gauge. This is because "fatigue" is better distributed in a tapering gauge tube, and also because the ends of the tubes have to be filled in order to "clean-up" after brazing, so that the extra thickness of the butted tubes is an insurance against undue weakening by over-filing. The frame tubes are joined by "lugs" or

FIG. 3.—THE "ORDINARY" BICYCLE, POPULAR FROM C. 1872-1885. With front wheels sometimes built over 5ft. in height, the racing models of this bicycle could attain a speed of 20 miles an hour.

FIG. 4.—AN EARLY "SAFETY" BICYCLE, C. 1885. SUCCESSOR TO THE "ORDINARY"

BY COURTESY OF MESSRS. SWIFT OF COVENTRY, LTD

FIG. 5.—A MODERN ROADSTER SAFETY BICYCLE. IN ITS PRESENT DAY FORM, WITH BALL-BEARINGS, PNEUMATIC TYRES, LIGHT FRAME AND WHEELS, POWERFUL BRAKES, AND COMFORTABLE SADDLE, THE BICYCLE IS A REMARKABLE PIECE OF ENGINEERING. IT EASILY CARRIES A LOAD OF TEN TIMES ITS OWN WEIGHT, OVER ALL SORTS OF ROAD SURFACES

sockets, which are made in various angles as necessary. Lugs were originally made of malleable iron castings, but light steel pressings have been found to save weight and to serve the same purpose. In brazing, the parts are heated to a dull red, and this work must be done very carefully to ensure, first, that sufficient brass is run into the joints, and secondly, that the tubes are not burned and weakened through over-heating.

Instead of brazing, acetylene welding can be employed, and lugs dispensed with. Welding leaves a smooth surface and is stronger, but in the event of breakage the whole frame must be renewed, whereas any single tube may be replaced in a brazed frame. Welding is rare in England, but commonly employed in France and Belgium.

Many improvements have been made in the method of housing the rear wheel in the frame, and on all racing bicycles, and many non-racing (called "roadster") bicycles, it is possible to remove or replace the rear wheel in a few seconds.

Wheels.—These consist of rims, spokes and hub. Rims may be of steel, aluminium alloy, wood or wood steel armoured. The first named is the most commonly used in England; whereas, in France and Germany wood and steel are both in wide use, while America, Belgium and Holland favour wood or wood steel armoured more than steel.

In the United States the wood steel armoured rim is used in a large majority of the bicycles manufactured. This rim has all the resiliency of a wood rim and having a thin covering or armour of sheet steel, is thereby protected against the action of the weather, splitting or warping.

Steel rims are made in 18 or 20 gauge and are rolled over at the edges to provide shoulders for the stiff wired edges of the tyres. Wood rims have similar shoulders where they are intended for this class of tyre, but in England these rims are more commonly used for the tubular racing tyre. Sizes of rims, throughout most bicycle-using countries, are expressed by the overall size of the tyre which fits the rim in question; thus, a rim described in England as 26 by 1½ in. is actually only about 23 in. in diameter, because the size of 26 in. refers to the diameter of the tyre when it is properly in position upon that rim. Aluminium alloy rims are non-rusting, and lighter than steel, but bulk must be added to provide the necessary strength.

Spokes are of steel wire, threaded and adjustable at the point where they pass through holes in the rims, while at the other end

they are bent at right angles to be hooked into holed flanges in the hubs. In England it is customary to fit 32 spokes to front wheels and 40 to rear wheels, but elsewhere the usual arrangement is 36 spokes in all wheels. Spokes may be plain (usually about 15 gauge) or double butted, *i.e.*, 15 or 16 gauge at each end and 17 or 18 gauge for the remainder. For tandem bicycles, carriers, etc., spokes of 14 gauge are used.

In hubs there is one row of ball bearings on each side, these bearings being adjustable by screwing either the outside ball-race (called the cup) in the hub-shell, or the inside ball-race (called the cone) on the spindle. The driving sprockets are screwed upon the shell, many modern European bicycles, particularly of the racing class, possessing a sprocket at each side of the hub. These sprockets are of different sizes, so that upon reversing the wheel in the frame, a different gear is obtained, or, in other words, the amount of travel obtained in one revolution of the crank is raised. Another common arrangement is a fixed sprocket on one side, and a free-wheel or floating sprocket on the other, which is very helpful to tourists. In the free-wheel the sprocket runs upon separate ball-bearings and has a ratcheted edge inside, so that the outer sprocket can drive the hub, but cannot itself be driven.

Another form of hub, called the coaster, is widely used in America, less popular in England and on the continent of Europe. This is a back-peddalling brake. When the pedalling action is reversed, a member is moved sideways on a quick thread inside the hub, and is made to expand a phosphor-bronze ring and bring it into contact with the inner surface of the hub-shell.

Variable Gears.—One of the most ingenious inventions in connection with bicycles is the device of varying the gear. It was first installed in the bottom bracket of the frame, forming part of the chain wheel. Soon afterwards a hub gear giving two different ratios—only one of them on a free-wheel—was invented, then a number of others, of which only the three-speed gear has survived in hub form. It is widely used in the British Isles and in parts of the British empire, and weighs about 2 lb. 2 oz. The drive runs solidly on the middle gear, but is taken through a train of small toothed wheels for the high gear (33½% increase) or the low gear (25% reduction). A small lever on the handlebar or the top frame tube effects the change through a stranded wire cable.

All gear-changing mechanism in bicycles is on the epicyclic principle, by which the toothed wheels or pinions are always in

mesh. The principle need not be described in detail here, but the following simple example will explain it: If a toothed wheel A is revolved round, and in engagement with a toothed wheel B, both being allowed to spin freely on their axis, they will spin at the same speeds. If, however, B is then held and prevented from spinning, A will spin much more slowly. Conversely, if A is held in the same way, B will spin more quickly. The drawback of

FIG. 6.—THE REVERSIBLE BICYCLE HUB WHICH GIVES TWO DIFFERENT GEAR RATIOS

epicyclic gearing in a bicycle is the difficulty of obtaining closer ratios than those mentioned.

Three-speed hubs are also made in England which incorporate a coaster or back-peddalling brake.

Many variable-gearing devices of particular value are used in the Alps and Pyrenees, where the gradients are so long that the cyclist who could not gear sufficiently low to surmount them on his bicycle would be compelled to spend many hours walking. The principle of most of these devices is a loose driving-chain which can be transferred from one sprocket to another mounted by its side. In some cases there are no fewer than three sprockets on the bracket axle, and three others on the hub. A wide range of gears is thus obtainable. This form of gearing is not favoured in England.

Bicycle Tyres.—These are nearly all of the pneumatic india-rubber type. There are two parts, the inner tube and the outer cover—terms which explain themselves. The inner tube contains a larger percentage of pure rubber. It is drawn from a tubing machine under high pressure, and emerges in circular form. Some cheaper tubes, however, are still manufactured from flat sheet rubber. Outer covers are built up on a cotton or flax fabric, the process being more or less elaborate according to the quality. The tread, or rubber surface that touches the road, is vulcanized on by a moulding press. Although this process destroys a small percentage of the resilience of the rubber, it also compresses it, with the result that if a piece of flint or glass cuts the tread afterwards,

FIG. 7.—THE PNEUMATIC TYRE, INTRODUCED IN 1889

On the left is a wired-on tyre cover for road use, and on the right, a tubular, or racing, tyre complete with inner tube

the cut tends to close itself, instead of opening wider. With hand-made tyres there is no vulcanization, the parts being joined by a solution of rubber in naphtha. As bicycles fitted with these tyres are considered easier to propel, they are sought for racing purposes, where the slightly greater vulnerability and cost are of less importance to the rider than speed.

Stiff wires are sewn into each edge of the outer cover, so that when the tyre is in place on the wheel-rim, the pressure from the air tube within forces the wires against the raised edges of the rim, which hold them securely. As the wires are of exactly the

right circumference, it is easy to see that if they are forced, at one place, down into the bed or centre of the rim, the wire on the opposite side of the wheel-circle will project sufficiently to enable it to be lifted over the edge of the rim.

Tubular tyres, used almost solely for racing purposes, are light and flexible. The outer cover completely encloses the inner tube, and it must be unstitched or unstuck when there is a puncture to be repaired. In the Constrictor tyre there are layers of loose threads at the base of the cover, which can be parted to enable a section of the inner tube to be extracted for repair. Tubular tyres are cemented to the rim.

Bicycle Brakes.—The rider brings his bicycle to a standstill by moving levers on the handlebar, which, through thin rods or stranded wire cables, cause small pads of leather, rubber or fibre to press against the wheel rims. These may act on the flat part of the rim, or, with what are known as calliper brakes, on the edges. The advantage of the latter type is that the wheel may be removed or replaced without disturbing the brake, whereas in the other type, the brake rods, with the shoes which hold them and the stirrup-shaped piece which carries the shoes, must be moved out of the way, to make room for the wheels to pass through. Rim brakes are used on front or rear wheels, or both, and on some English bicycles a single lever will apply the front and rear brake simultaneously.

Bracket.—This is the junction of the bottom, seat and chain stay tubes, and carries the toothed wheel driving the chain, and the cranks and pedals by which the rider turns the toothed wheel (known as the chain-wheel). The bracket consists of a cylindrical shell, in which a steel axle is mounted on ball bearings. A toughened steel crank is secured to each end of the axle, the length of this crank varying from $6\frac{1}{2}$ to 7 inches. At the other end of each crank is the pedal, consisting of a framework mounted by ball bearings on a spindle, which screws into the crank. No locking device is necessary, as the right-hand pedal has a right-hand thread, and the left-hand pedal a left-hand thread, so that the pedalling action tends to tighten up each pedal more securely in the crank. The right-hand crank carries the chain wheel, being fastened by bolts and nuts, or welded to it, or forced into it by means of a male or female taper with a serrated surface. This cannot be taken apart after fixing.

In the United States the "one-piece" type of crank is in almost universal use—that is, both cranks and axles are made from a one-piece forging, heat-treated to give spring temper, and the ball cups, cones, etc., so designed as to be easily assembled in the bracket.

The driving sprocket is attached to the crank by being pressed on a shoulder of special design or the sprocket is driven through a lug on the crank, and is easily detachable.

The chain is very light, and accurately made, consisting of mild steel links, fastened by hand steel rivets. Each rivet is covered by a sleeve called the bush, and on most chains, but not all, this bush is covered by a roller which turns freely when the tooth of the chain-wheel or the hub-sprocket bears against it. Chains of half-inch links are almost universal, but one inch is frequently used for racing purposes. The width of the driving surface of a bush or roller is almost invariably one-eighth of an inch.

Bicycle seats are of leather or of a rubber and fibre composition, mounted upon springs. Many shapes, sizes and degrees of springiness are available, including special shapes for persons suffering from perineal maladies.

Handlebars are bent of mild steel, usually one inch in diameter, and carry the brake-levers, in addition to the warning bell. Handlebars are frequently covered with some material giving a comfortable hold to the rider, such as celluloid, rubber-sponge, etc. They are used in a great variety of shapes. Generally they bend upwards on "roadster" bicycles and downwards on racing bicycles or when faster speed or more power is desired. Flat handlebars are a useful compromise.

The tandem is designed to carry two persons, both of whom pedal in unison. The pedalling gear, saddle, handlebar, etc., are therefore duplicated. The frame tubes, wheel spokes, rims, tyres, etc., on a tandem are heavier and stronger than on single bicycles.

Statistics.—It is estimated that over 30 million bicycles are in use throughout the world, but there are no means of obtaining exact figures. In a few countries a system of registration is in force, and, accepting this as a basis, the following figures are approximately correct for 1926:—

Country.	Bicycles in use.
Austria	800,000
Czechoslovakia	600,000
Denmark	1,000,000
France	7,102,000
Holland	2,400,000
Italy	2,000,000
Japan	441,000
South Africa	41,000

Though the estimates vary widely, it may be accepted that there are, at the fewest, as many bicycles in use in Great Britain as in France—probably more in summer.

FROM "CYCLING"

FIG. 8.—THE TANDEM BICYCLE, IN WHICH STEERING AND CONTROL ARE BY THE FRONT HANDLEBARS. THE BACK PART OF THE FRAME IS CONSTRUCTED FOR A WOMAN RIDER

The following may be accepted as approximately the annual production of bicycles in the countries named —

Country.	Bicycles.
Germany	450,000
Great Britain	680,000
Italy	80,000
Netherlands	135,800
Sweden	126,092
U.S.A.	325,000

As the largest producer of bicycles, Great Britain naturally has the greatest export trade. The following are the export figures for 1926:—

Country.	Bicycles.	Average value.	
		£.	s.
Great Britain	280,051	4	6
U.S.A.	5,348	5	16
Belgium	8,026	3	7
Germany	64,507	5	1
Holland	22,570	3	0
Sweden	4,130	6	2
Italy	13,067	4	18

The imports of bicycles into Great Britain are very small compared with the exports, in 1926 only 1,251 were imported, valued at £5,921. A brisker import trade exists in cycle parts, of which £386,034 worth were imported into Great Britain in 1926. It should be noted, however, that during the same year £1,804,006 worth of parts were exported from Great Britain.

Experiments in adding engines to bicycles to render them independent of human propulsion began in 1885 (see MOTOR CYCLES).

(B. W. BE.)

BIDA, a town of West Africa in the Niger (formerly Nupe) province of Northern Nigeria, on the Baro-Minna branch of the Lagos-Kano railway. It lies 25m. E. of the Niger in 9° 5' N., 6° East. It was founded in 1859 when Fula rule was established in Nupe; it is a walled town of considerable size. The inhabitants, mostly Hausa, carry on an extensive trade and are especially noted for their embossed brass and copper work. The Bida goblets, in which brass and copper are beautifully blended, are of extremely elegant design. The manufacture of glass and the dyeing of cloths are other industries. The streets are planted

with huge shade-trees, so that as Bida is approached it looks like a forest.

In 1897 there was a two-days' fight outside the walls of Bida between the forces of the emir of Nupe and those of the Royal Niger Company, ending in the defeat of the Fula army (mostly cavalry). It was not, however, until 1901 that Bida, and with it Nupe, came under effective British control (see NUPE and NIGERIA: History).

BIDDEFORD, a city of York county, Maine, U.S.A., on the Saco river, 6m. from its mouth, opposite Saco and 15m. southwest of Portland. It is on Federal Highway 1 and the Boston and Maine railroad. The population was 16,145 in 1900; 18,008 in 1920, of whom 6,338 were foreign-born white, and was estimated to be 18,532 in 1925. The city has abundant water-power, and manufactures cotton goods, shoes, lumber, cotton-mill machinery and other articles. The output of its 25 establishments in 1925 was valued at \$16,546,310. There are large granite quarries in the vicinity. Biddeford Pool and Fortune Rocks, two summer resorts on the coast, are within the city limits. The Saco river was discovered in 1603, and the first settlement was made (on the Biddeford side, at the mouth of the river) in 1616 by Richard Vines. In 1630 he took possession of a grant including the present site of the city. "Biddeford" was adopted as the name in 1751, and in 1855 the city was incorporated.

BIDDER, **GEORGE PARKER** (1806-1878), English engineer, was born at Moreton Hampstead, Devon, on June 14, 1806, and died at Dartmouth on Sept. 28, 1878. As a child he had an extraordinary capacity for computation, and his father, a stone-mason, exhibited him as a "calculating boy." From this career he was rescued by Sir John Herschel and Sir Henry Jardine, and sent to school and to Edinburgh university. He was employed by George Stephenson in parliamentary work in connection with railway development in the 'forties, and then by R. Stephenson in the designs for the Great Eastern Ry. (L.N.E.R.) and railways in Belgium and Scandinavia. He was one of the founders of the Electric Telegraph Company, and the designer of the Victoria docks (London).

BIDDERY or **BIDRI** (an Indian word, from Bedar or Bidar, a town in the Nizam's dominions), an alloy of copper, lead, tin and zinc used in making various articles and ornaments which are inlaid with gold and silver.

BIDDING-PRAYER, the formula of exhortation to prayer said in England before the sermon in cathedrals, at university sermons, in the Inns of Court, and elsewhere on special occasions. Such formulae are of great antiquity in both eastern and western Churches. The characteristic feature is that the minister tells the people what to pray for. Thus in England in the 16th century they were told what to remember in "bidding their beads" (O. E. *biddan*, to pray, cf. Ger. *beten*). In course of time the word "bid" in the sense of "pray" became obsolete, and the bidding-prayer has come to mean the exhortation itself.

BIDDLE, **JOHN** (1615-1662), frequently called the father of English Unitarianism, was born at Wotton-under-Edge, in Gloucestershire. He was educated at the grammar school of his native town and at Magdalen Hall, Oxford, being subsequently appointed to the mastership of the free school in the city of Gloucester, where "he was much esteemed for his diligence in his profession, serenity of manners, and sanctity of life." A treacherous friend obtained the ms. of his *Twelve Arguments drawn out of Scripture, wherein the commonly received opinion touching the deity of the Holy Spirit is clearly and fully refuted*; and in Dec. 1645 he was summoned before the parliamentary committee then sitting at Gloucester, by which he was committed to prison. He was released on bail after a short imprisonment, but in July 1647 was called before parliament, which desired to enquire into his views. After tedious proceedings, during which Sir Henry Vane befriended him, Biddle was committed to custody, and his *Twelve Arguments*, which he had now published, was ordered by parliament to be seized and burned by the hangman. Notwithstanding this and the ordinance of May 2 1648, visiting denial of the doctrine of the Trinity with death, Biddle issued two tracts, one a *Confession of Faith touching the Holy*

Trinity, and the other *The Testimonies of Irenaeus, etc., concerning the one God and the Persons of the Trinity* (1648). These were suppressed, and the Westminster assembly of divines eagerly pressed for the death penalty for heretics like Biddle. This, however, was resisted by the army, and by many of the Independent parliamentarians; and after the death of the king, Biddle was allowed to reside in Staffordshire under surveillance. He engaged in preaching and in literary work, particularly an edition of the Septuagint, published by Roger Daniel. In Feb. 1652 the general act of oblivion gave him complete freedom, and his adherents soon began to meet regularly for worship on Sundays. They were called Biddellians, or Socinians, or Unitarians, the name which has now become associated with their opinions. Biddle was not left long in peace. He translated some Socinian books, among others the *Life of Socinus*, and published two catechisms which excited a fury of indignation. He was summoned before the parliament in Dec. 1654 and imprisoned. The dissolution of that body again set him at liberty for a short time, but he was presently re-arrested and was only rescued by Cromwell, who sent him (Oct. 1655) out of the way to one of the Scilly islands, allowed him 100 crowns a year, and in 1658, on the solicitation of many friends, released him. For a few years he lived and taught quietly in the country, but, returning to London, he was, in June 1662, again arrested, and fined £100. As he was unable to pay this sum, he was at once committed to prison, where he died of fever.

BIDDLE, NICHOLAS (1786–1844), American financier, was born in Philadelphia on Jan. 8, 1786. During 1804–07 he was the secretary, first of John Armstrong, minister to France, and then of James Monroe, minister to Great Britain. He was an associate editor of Dennie's *Portfolio*, and prepared a *History of the Expedition under the command of Captains Lewis and Clark* (1814). In 1819 he became a director of the Bank of the United States. The bank's national charter lapsed in 1836, but it was immediately chartered by Pennsylvania as the "Bank of the United States of Pennsylvania"; and Biddle remained president until 1839. He took a prominent part in the establishment of Girard college in accordance with the will of Stephen Girard (q.v.). He died in Philadelphia on Feb. 27, 1844.

His son, **CHARLES JOHN BIDDLE** (1819–73) served in the Mexican War as a captain of infantry. He practised law in Philadelphia; was a representative in Congress in 1861–63; was long editor-in-chief of the *Philadelphia Age*; and published "The Case of Major André, with a Review of the Statement of it in Lord Mahon's History of England" in the *Memoirs of the Historical Society of Pennsylvania* (1858).

The best account of Nicholas Biddle's administration of the bank may be found in an excellent work by Ralph C. H. Catterall *The Second Bank of the United States* (Chicago, 1903).

BIDEFORD, municipal borough on north coast of Devonshire, England, 8½ m. south-west of Barnstaple. Population (1921) 9,125. It is situated on two hills rising from the banks of the river Torridge, 3 m. above its junction with the estuary of the Taw.

Bideford (Bedeford, Bydyford, Budeford, Bytheford) is not mentioned in pre-Conquest records, but according to Domesday it rendered geld for three hides to the king. From the time of the Conquest down to the 18th century, Bideford remained in the possession of the Grenville family, and it first appears as a borough in an undated charter (probably of the reign of Edward I) from Richard de Grenville, granting liberties similar to those in use at Breteuil and a market every Monday. A charter (1573) created Bideford a free borough corporate with a common council. This charter also granted the Tuesday market, which is still held. A subsequent charter (1610) continued in force until the Municipal Corporations Act of 1873. In the 16th century Sir Richard Grenville, the famous Virginian settler, did much to stimulate the commercial development of Bideford, which long maintained a very considerable trade with America, Spain and the Mediterranean ports, the import of tobacco from Maryland and Virginia being especially noteworthy.

Many of the houses are built with timber framework in

Elizabethan style, and the two parts of the town are united by a bridge of 24 arches, originally erected in the 14th century, when the revenue of certain lands was set apart for its upkeep. The church of St. Mary is modern save an old tower. A stone chancel screen and a Norman font are also preserved. Industries include the manufacture of earthenware, leather goods, sails, ropes and linen, and iron-founding. The small harbour has about 17 ft. of water at high tide, but is dry at low tide. Anthracite and a coarse potter's clay are found near the town.

Bideford is a support of Barnstaple (q.v.) with some coastal shipping. It has a station on the Southern railway and a car service by the Bideford, Westward Ho! and Appledore railway. The borough is governed by a mayor, four aldermen and 12 councillors. Area, 3,416ac. It forms part of the Barnstaple parliamentary county division.

BIDJUGO, an island fishing population of the Ilhas dos Bissagos of Portuguese Guinea living in 17 villages, and ruled at present by an elected queen.

See de Coutouly, "La population de l'Archipel des Bissagos," *Revue d'Ethn. et Trad. pop.* (1921).

BIDPAI, FABLES OF, the name under which a famous collection of fables of Indian origin became known in Europe in the middle ages. The original Sanskrit work, composed by a Brahman in the 3rd century A.D., still very popular in India as the *Pañcatantra* and its shorter recension the *Hitopadeśa* ("book of good counsel"), was a mirror for princes, conveying practical wisdom in the form of beast-fables under five heads (*pañcatantra*). It was translated with additions from the Sanskrit into Pehlevi for the Sassanian king Khusraw I Anūsharwān (A.D. 531–597) by his physician Burzoe. This Pehlevi version is no longer known, but a Syriac translation from it made in the 6th century still survives. About 200 years later 'Abd Allāh b. al-Muḳaffā' (born c. A.D. 725) translated Burzoe's book into Arabic, with certain additions as an exercise in style. This version, known as *Kalīlah wa Dimna* from the names of the two jackals in the first book, although intended only for amateurs of belles-lettres, attained wide popularity on account of its subject matter. It is in a preface to an edition of it by an otherwise unknown Bahnūd b. Saḥwān that its composition is ascribed to an Indian sage named Bidpā. Ibn al-Muḳaffā's version was soon translated into Persian, Eastern and Ottoman Turkish, Mongol, Malay and Ethiopic. A Hebrew version made at the beginning of the 12th century by a certain Rabbi Jō'el was translated into Latin by a converted Jew named John of Capua for Cardinal Ursinus in the third quarter of the 13th century with the title *Directorium Vitae Humanae*; on this Latin text are based all the translations into the languages of western Europe (except an independent Spanish version of Rabbi Jō'el and of course those by modern orientlists). About the same time Ibn al-Muḳaffā's book was translated into Greek by Simeon son of Seth and thence into Latin, German and the Slavonic languages.

Among the Persian translations of the *Kalīlah wa Dimna*, that by Kāshifi (d. 1504), called *Anwār-i Suhailī* (The Lights of Canopus [Suhail]) in honour of his patron Ahmad Suhailī, attained great popularity as a model of style—(it is absurdly artificial and bombastic to the European taste). Through its use as a Persian text-book by the East India company, this became known in Europe and was translated into most European languages just as its ancestor, *Kalīlah wa Dimna*, had been five centuries before. Through one or other of these versions, the *Pañcatantra* has been translated into all the languages of Europe and India and all the languages of the Muslim world from Berber to Mongol and Madurese. The shorter recension of the *Pañcatantra*, the *Hitopadeśa* became known to Europeans at the end of the 18th century and has since been translated into most European languages.

BIÉ: see ANGOLA.

BIEBRICH, a town of Germany, in Hesse-Nassau, on the right bank of the Rhine, 3m. S. of, and river-port for, Wiesbaden. Pop. (1925) 21,260. The palace of the former dukes of Nassau occupies a fine position on the river bank. Biebrich is an important steamboat station for both passenger and cargo traffic; trade is in cement and aniline dyes, and in the wines of the district.

BIEDERMANN, FRIEDRICH KARL (1812-1901), German publicist and historian, was born at Leipzig Sept. 25 1812, and after studying at Leipzig and Heidelberg became professor of philology in the university of his native town in 1838. His early writings show him as an ardent advocate of German unity, and he was a member of the national parliament which met at Frankfurt in 1848. Becoming a member of the upper house of the parliament of Saxony, he advocated union under the leadership of Prussia. He was imprisoned in 1854 for editing *Deutschen Annalen*, and subsequently retired to Weimar, where he edited the *Weimarsche Zeitung*. Returning to Leipzig in 1863 he edited the *Deutsche Allgemeine Zeitung*, and regained his professorship in 1865. He was again a member of the Saxon upper house, and from 1871 to 1874 a member of the German Reichstag. He died at Leipzig on March 5, 1901.

Biedermann's chief works are: *Erinnerungen aus der Paulskirche* (1849); *Deutschland im 18. Jahrhundert* (1854-80); *Friedrich der Grosse und sein Verhältnis zur Entwicklung des deutschen Geisteslebens* (1850); *Geschichte Deutschlands 1815-71* (1891); *Deutsche Volk- und Kulturgeschichte* (1901). He also wrote the dramas, *Kaiser Heinrich IV.* (1861), *Kaiser Otto III.* (1862) and *Der letzte Bürgermeister von Strassburg* (1870).

BIEKKICH: see BIEBRICH

BIEL, GABRIEL (d. 1495), scholastic philosopher, born at Spiers (Speier). He was the first professor of theology at the newly founded (1477) University of Tübingen, of which he was twice rector, and at some uncertain date entered the Order of the Brothers of the Common Life. His work consists in the systematic development of the nominalistic theories of his master, William of Occam, these theories being expounded in his *Epitome et Collectorium ex Occamo super libros quatuor Sententiarum* (1508, 1512, and various dates). The empirical individualism of the work, together with scattered utterances on special points, which gained for Biel the title of *Papista Antipapista*, had considerable influence in giving form to the doctrines of Luther and Melancthon. It is the best specimen of the final aspect of scholasticism. His other works also have been frequently reprinted. Besides theological works, Biel has a treatise *De Potestate et Utilitate Monetarium*, which gives him a place in the history of economic theory. The title *Ultimus Scholasticorum* is often wrongly bestowed on Biel: scholasticism did not cease with him even in Germany and continued to flourish long after his time in the universities of Spain.

See Linsenmann in *Theol. Quartalschrift* (Tübingen, 1865); H. Plitt, *Gabriel Biel als Prediger* (Erlangen, 1879); W. Roscher, *Geschichte der National-ökonomik* (Munich, 1874), pp. 21-28.

BIELEFELD, chief town of a subdivision of the district of Minden, north-eastern Westphalia, Prussia, c. 40m. E. by N of Münster. Pop. (1925) 86,052. It is situated at the foot of the Teutoburger Wald, and consists of two portions, separated by the river Lutter, which were first united into one town in 1520. Bielefeld is mentioned as early as the 9th century, as *Belanvelde*. It joined the Hanseatic league in 1270. In 1347 the town passed with the countship of Ravensberg to the duchy of Julich, and in 1666 to that of Brandenburg. Among its public buildings and institutions are the old town church, with a curious carved altarpiece, and the town hall. Above the town lies the old castle of Sparenburg, built in the 12th century by Bernhard, count of Lippe. It was restored after its destruction by fire in 1877 and now contains a historical museum. Bielefeld is the centre of the Westphalian linen industry, which dates from the 13th century, and was extended by Dutch settlers in the 16th and 17th centuries. It has also important plush, silk and hosiery manufactures and extensive bleaching works, and does an extensive export trade. Engines, automobiles, glass, furniture and paper are also made.

BIELITZ, a town of Poland in Cracow (Czech. *Bilsko*, Polish *Bielsko*), 40 m. S.E. of Ratibor. It is one of a series of towns in the border zone between the Carpathian mountains and the plain of Eastern Europe. It is situated on the river Biala a small tributary of the upper Wista (Vistula), just opposite the town of Biala. Bielitz, founded in the 13th century, was an important fortified town in the 15th and 16th centuries. It has a castle associated with the Sulkowsky family in favour of whom the lordship of Bielitz was raised to a duchy in 1752. It is an important weaving centre with much trade in woollens and linen. It also manufactures jute and machinery. After the war of 1914-18 Bielitz was in disputed territory and passed from Austrian to Polish hands as a result of the Treaty of St. Germain-en-Laye, Sept. 10, 1919.

BIELLA, episcopal sec., Piedmont, Italy, province of Novara, 55m N.E. of Turin by rail, and 38m. direct, on the southern edge of the lower Alps. Pop. (1921) town 22,146; commune 25,221. The old upper town (1,558ft.) and new lower town are linked by cable tram. Fine palaces with terra-cotta decorations and a modern bath establishment are in the old town. The new town contains the cathedral and the fine Renaissance church of S. Sebastiano; near the former is a baptistery of the 9th century. It is (and has long been, for the statutes of the wool industry go back to 1312) a considerable manufacturing centre for woollens, silks and cottons.

BIENNE or **BIEL**, an important industrial town in the Swiss canton of Berne, at the north-eastern end of the Bielersee, where the river Suze or Scheuss issues from a deep cleft (the Taubenloch) in the Jura range, 19m N.E. of Neuchâtel, and 21m. N.W. of Berne. Its chief industries are watch-making, chain-making, the manufacture of machines and other objects for use on railways, etc. The West Cantonal Technical institute gives instruction in these subjects. The population, which in 1850 was but 3,589 and rose in 1928 to 37,150, was mainly Protestant, and two-thirds German-speaking. The parish church of St. Benedict dates from 1451, but was restored in 1775—it has some fine 15th-century painted glass. In the town is the Schwab museum, chiefly notable for its fine collection of objects from the pile-dwellings. To the north-west, two funicular railways lead up to Évilard (or Leubringen) and Macolin (or Magglingen), both situated on the slope of the Jura.

First mentioned in the 12th century, Biemme was for centuries under the jurisdiction of the prince-bishop of Basle. In 1279 (permanently in 1352) it made an alliance with Berne, in 1334 and 1344 with Soleure, and in 1311 and 1382 with Fribourg. It failed to gain admission into the Swiss confederation, though after it adopted the Reformation in 1528 it was closely associated with the Protestant cantons. In 1798 it was seized by the French, but in 1815, with the greater part of the bishopric of Basle, it became part of the canton of Berne.

See C. A. Bloesch, *Geschichte der Stadt Biel* (to 1854) (Biel, 1855-56); also *Bieler Neujahrsblätter* (1908-10); *Bieler Jahrbuch* (1927, 1928).

Lake of Biemme, or **BIELERSEE**, a Swiss lake, is situated at the foot of the Jura range. It is 7½m long, 2½m. wide, its greatest depth 249ft., its surface 1,424ft. above the sea, and its area 168sq m. In it is the Isle of St. Pierre with many traces of lake dwellings. It receives the R. Suze or Scheuss and the R. Thièle or Zihl (from Lake Neuchâtel). The Hagneck canal leads the waters of the Aar into the lake and the Nidau conducts them out again.

BIENNIALS, the name applied to plants which normally complete their life-cycle in two years, usually devoting the first to laying up a store of food, the second to flowering. This period is not, however, fixed, as if food is scarce the plant may delay flowering for more than one year, or may flower in the first year as in the bolting of such a plant as the beet.

BIERCE, AMBROSE (1842-), American satirist, story-writer and poet, was born on a farm in Meigs county (Ohio), on June 24, 1842, the son of Marcus Aurelius and Laura Sherwood Bierce. His father had little money, but a good library, and instead of a formal education the boy read widely. In 1861 he entered the Confederate army as a volunteer, served throughout the

Civil War, was twice severely wounded, and was breveted a major for bravery. At the end of the war he went to San Francisco; tossed a coin, it is said, to decide his vocation, and entered journalism as editor of the *News Letter*. He went to London in 1872, where, because of his caustic humour revealed in the periodical, *Fun*, and in three thin volumes, *Nuggets and Dust*, 1872, *The Fiend's Delight*, 1873 and *Cobwebs from an Empty Skull*, 1874, he became famous as "Bitter Bierce," and was engaged by friends of the exiled empress Eugénie to edit *The Lantern*, a periodical inaugurated to defend her against rumoured newspaper attacks on a visit to England. But her enemies were prematurely frustrated by the arrangement, and Bierce returned to San Francisco (1876).

Except for a short period of mining near Deadwood (S.D.), he remained in San Francisco for 25 years writing for *The Wasp* and the *Argonaut* and conducting on the *Examiner* a weekly column, "Prattle," which has been described as the most eagerly devoured column of causerie ever printed in America, and in which it is said he made and devastated reputations, literary and political.

Throughout the early '80s he wrote short stories without once finding an editor who would publish any of them. In 1891 the publication of a collection of them, *Tales of Soldiers and Civilians* (published as *In the Midst of Life*, 1899, 1909 and 1927), was financed by a San Francisco merchant. The next year *The Monk and the Hangman's Daughter*, a masterly rewriting and elaboration of a translation by G. Adolphe Danziger from the German, was published in Chicago, and *Can Such Things Be?* a collection of stories of the supernatural, was published in 1893. His book of verse, *Black Beetles in Amber*, appeared in 1892; *Fantastic Fables* (1899); *Shapes of Clay* (1903); *The Cynic's Word Book*, 1909 (published as *The Devil's Dictionary* 1925); *Write It Right*, a black list of literary faults (1909); and *The Shadow on the Dial* (1909), a book of essays covering among other things "government, dreams, writers of dialect and dogs." In 1909-12 his collected works were published in Chicago. In 1896 Bierce was sent to Washington to fight through the Hearst papers the Funding Bill of the Central Pacific railroad, and a year later he returned to Washington to live, corresponding for the New York *American* and conducting a department in the *Cosmopolitan*. In 1913, at 71 he left for Mexico "with a pretty definite purpose, which, however, is not at present disclosable." He never returned, and, though persistent rumours have appeared in the press as to his death at the hands of Mexican revolutionists, none of them has been substantiated.

See *The Letters of Ambrose Bierce*, with an introduction by Bertha Clark Pope (1922); Van Wyck Brooks, *Emerson and Others* (1927); Vincent Starrett, *Ambrose Bierce* (Chicago, 1920); and Percy H. Boynton, *More Contemporary Americans* (Chicago, 1927).

(W. Tu.)

BIERSTADT, ALBERT (1830-1902), American landscape painter, was born in Solingen, Westphalia, Germany, on Jan. 7, 1830, and was taken to the United States when about a year old. In 1853-1856 he studied painting at Düsseldorf. His pictures of the western part of the United States, and particularly the Rocky Mountains, made him widely popular. His "Estes Park, Colorado," is in the collection of the earl of Dunraven; his "Sierra Nevada" (1878) is in the Corcoran gallery in Washington, and "The Valley of Yosemite" in the James Lenox collection in New York. He rendered panoramic views with a certain ability, though his work was rather topographically correct and impressive than artistic. He was a member of the National Academy of Design of New York, and is represented by two historical paintings, "The Discovery of the Hudson River," and "The Settlement of California," in the Capitol in Washington (D.C.). He died in New York city on Feb. 18, 1902.

BIFROST, in Old Norse mythology, the rainbow, which was supposed to form the bridge guarded by Heimdal, god of light, by which the gods passed between heaven and earth.

BIGAMY, in English law, according to the statute now in force (Offences against the Person Act 1861, s. 57), is the offence committed by a person who "being married shall marry any other person during the life of the former husband or wife, whether the second marriage shall have taken place in England or Ireland or elsewhere." It is a felony and is punishable by

penal servitude not exceeding seven years or by imprisonment with or without hard labour for not more than two years. By the same act of parliament the offence may be dealt with in any county or place where the defendant shall be apprehended or be in custody. The following clause embodies the necessary exceptions to the very general language used in the definition of the offence: "Provided that nothing in this section contained shall extend to any second marriage contracted elsewhere than in England and Ireland by any other than a British subject, or to any person marrying a second time whose husband or wife shall have been continuously absent from such person for the space of seven years then last past, and shall not have been known by such person to be living within that time, or shall extend to any person who at the time of such second marriage shall have been divorced from the bond of the first marriage, or to any person whose former marriage shall have been declared void by any court of competent jurisdiction." By the Criminal Justice Administration Act 1914 the wife or husband of a person charged with bigamy is a competent but not a compellable witness (*R. v. Leach*, 22 Cox C.C. 721).

A valid marriage must be proved in the first instance in order to support a charge of bigamy. A voidable marriage, such as one voidable for impotence, will be sufficient, but a marriage which is absolutely void will not. For example, if a woman marry B during the lifetime of her husband A, and after A's death marry C during the lifetime of B, her marriage with C is not bigamous, because her marriage with B was a nullity. In regard to the second marriage (which constitutes the offence) the English courts have held that it is immaterial whether, but for the bigamy, it would have been a valid marriage or not. An uncle, for example, cannot marry his niece; but if being already married he goes through the ceremony of marriage with her he is guilty of bigamy. In an Irish case, however, it has been held that to constitute the offence the second marriage must be one which, but for the existence of the former marriage, would have been valid, but this was disapproved by the Court for Crown cases reserved in *R. v. Allen*, L.R. 1 C.C.R. 367. It is a good defence to a charge of bigamy that the accused after proper inquiries in good faith and on reasonable grounds believed the first spouse was dead, even although seven years have not elapsed (*R. v. Tolson*, 16 Cox C.C. 629). Further, if a person charged with bigamy in England can prove that he has been legally divorced by the law of the country where the divorced parties were domiciled at the time (even though the ground on which the divorce was granted was not one that would justify a divorce in England) it will be good defence to the charge. But a bona fide belief on reasonable grounds that a divorce is valid affords no defence (*R. v. Wheat & Stocks*, 26 Cox C.C. 717). Criminal jurisdiction is always regarded as purely territorial, but bigamy (together with homicide and treason) is an exception to this rule. A British subject committing bigamy in any country may be tried for the same in the United Kingdom (Earl Russell's case, 1901, 20 Cox C.C. 51, where the words "or elsewhere" were held to mean "in any other part of the world"). American law as regards bigamy is similar to English law.

(W. DE B. H.)

BIG BERTHA, the nickname of the German long-range gun (from Frau Bertha von Bohlen, principal proprietor of Krupp's factory, where it was made), which in 1918 shelled Paris from the forest of Coucy at a range of 76 miles. The bombardment commenced on March 23 and extended over 140 days, firing taking place about every third day; 256 people were killed, but the moral effect, after the first day, was slight. The most serious losses were caused on Good Friday, March 29, when 156 were killed or wounded in the church of St. Gervais. The piece was a high velocity gun made by boring out a 15 in. naval gun and inserting a projecting tube of 21cm. calibre which was re-bored to a larger width as it became worn, and by lengthening the muzzle increased the range. The weight of the shell fired was 264 lb. and that of the piece, which was on a railway mounting, 142 tons.

BIG BUSINESS, a term which first came into use in the United States at the beginning of the 20th century, to denote the huge aggregations of capital and enterprise which are growing

up in many industrial countries. The first impulse to form these large aggregations was due to the great area, abundant raw materials and immense markets of the United States, and was in the nature of things probably inevitable. A good example of "big business" is the United States Steel Corporation, which was a fusion, in 1901, of ten extensive plants, many smaller plants and other valuable properties, with a capitalization of \$1,370,000,000 in stocks and bonds. This corporation is one of the very largest industrial organizations and the leading iron and steel producer in the world, with steel ingot production in 1927 of 18,500,000 tons, or 55% of the steel production of the United States. An early example of "big business" was the Standard Oil Company, originally incorporated at Cleveland, O., in 1870, with a capital of \$1,000,000. By 1879 it produced 95% of the refined oil of the United States. Its extraordinary success, and methods like the receipt of rebates from railroads aroused keen opposition.

In July 1890 the Sherman Anti-Trust law declared illegal all combinations in restraint of trade. In 1892 the U.S. Supreme Court ordered the Standard Oil Company dissolved into its 20 constituent companies, but the *pro rata* distribution of stock among subscribers left the combined strength of the companies practically intact. The consolidated income account of the Standard Oil Company of New Jersey, one of the constituent companies, reported gross operating income for 1927 as \$1,256,500,000. In Dec 1902 the International Mercantile Marine consolidated the White Star and four other steamship lines with combined tonnage of over 1,000,000 tons, and with bonds and stock valued at \$170,000,000. Decisions of the U.S. Supreme Court and the more liberal provisions of the Clayton Anti-Trust law of October 1914 marked the growing acceptance of the principle of aggregation.

Wide distribution of ownership is a feature of "big business." Thus the American Telephone and Telegraph Company, comparable in size with the United States Steel Corporation, at the beginning of 1928 had more than 525,000 stockholders, the average holding being 26 shares. The encouragement of employees to purchase stock is another feature of "big business," as represented by the United States Steel Corporation, the Pennsylvania railroad, the Standard Oil Company and other great corporations. This brings stability through a sense of common interest. American labour may possibly also be said to have entered "big business," one trade union (the Brotherhood of Locomotive Engineers) at one time owning banks, large office buildings and coal mines.

BIGELOW, JOHN (1817-1911), American journalist and diplomat, was born at Malden (N.Y.), on Nov. 25, 1817. He graduated at Union college in 1835, practised law in New York, was joint owner (with William Cullen Bryant) and managing editor of the New York *Evening Post* (1849-61); was United States consul at Paris in 1861-64, and minister to France in 1864-67. While consul, Bigelow wrote *Les États-Unis d'Amérique en 1863* to counteract the apparent desire of the French for a dissolution of the American Union, by showing them the relative importance of the commerce of the northern and southern states. On discovering, in 1863, that a French shipbuilder, with the connivance of Napoleon III., was constructing two ironclads and two corvettes for the Confederacy, he succeeded in preventing the delivery of three of these vessels to Confederate agents. In his work, *France and the Confederate Navy* (New York, 1888), he gives an account of this episode. In 1865-66, it devolved upon him as minister to France, to represent his Government in its delicate negotiations concerning the French occupation of Mexico, and he discharged this task with credit. From 1875 to 1877 he served as secretary of state of New York. He wrote books of travel, of popular biography, and of historical or political discussion, etc., but his principal literary achievements were editions (1868 and 1888) of Franklin's autobiographical writings, copiously annotated; and of the complete works of Franklin (New York, 1887-89), based in part upon the editor's personal investigations of manuscript sources in France and elsewhere. Bigelow, a close friend of Samuel J. Tilden, became the latter's literary executor, editing his speeches and other political writings (1885), publishing a biography in 1895, and editing a two-volume collec-

tion of Tilden's letters and literary memorials (1908). He also wrote a biography of William Cullen Bryant (1890). In 1897 he published a volume entitled *The Mystery of Sleep* (2nd ed., 1903). In 1909 he published *Retrospections of an Active Life*, covering his career to 1866. He died in New York on Dec. 19, 1911; and two additional volumes of the *Retrospections*, ending with 1879, were issued by his son in 1913.

BIG GAME HUNTING. The pursuit of large game probably shares with the lust for gold the credit for drawing the majority of explorers into the unknown, and there can be no doubt that such pursuit has always exercised the greatest fascination for mankind. In the past fifty years conditions have changed greatly and at the present time there would be comparatively few easily accessible big game fields left in the world had it not been for timely protection.

The actual methods of hunting depend on the type of country in which the game is found, and on the size and habits of the creatures themselves. In open country which is free from any trees or bush it is obvious that game can be viewed from afar, the actual distance depending on the contour of the ground. In these conditions a slow and stealthy approach is necessary before a shot can be obtained, use being made of every tuft of grass, rock, or hollow as a means of concealment and attention being paid to the direction of the wind. This is known as "stalking."

In dense bush or scrub it is, however, impossible to see beyond a few yards. Any animal which is sighted will be well within shot when it is seen, so there is no need of a long approach to get within range. Game in these conditions is come upon suddenly, and the best chance of getting a shot is to walk slowly and cautiously through the forest, ever on the alert. This form of hunting has been described by different names but none is so graphic or realistic as the American "still hunting."

There are some animals which cannot be followed in this manner. Such are mostly big beasts which herd together, as do elephants. They leave well defined tracks, or spoor, in soft ground and even on hard ground a skilful hunter can follow their trail and eventually track them down. "Tracking" describes this work.

There are other animals which inhabit or else retire to patches of dense jungle so thick that it is impossible for any man to make a sufficiently silent advance to within shooting distance or view his quarry without first giving the alarm and frightening it away. Tracking and still hunting are out of the question and here the best chance of success is to drive the animal out into the open where a shot can be obtained, or at any rate along some path where the sportsman is waiting. This can only be done with the help of a number of men or else with a line of elephants as used in certain parts of India, and this method is universally known as "driving" or "beating." If, however, men or elephants are not available in circumstances such as these, the only course for the sportsman to adopt is to wait in hiding over some spot where the animal will probably pass or return. Such a place may be either a water hole, or a salt lick, or, in the case of beasts of prey, a half-eaten kill. This waiting method is known as "sitting up." It should, however, be stated that sitting up over water or a salt lick is not generally considered a sportsmanlike procedure and is prohibited by law in some countries.

In America there is yet another form of hunting which is commonly practised in pursuit of moose, but can be used with almost all species of deer; this is known as "calling." Calling consists in waiting in hiding and making a noise in imitation of the call of a cow or hind during the rutting season or else of the challenge of a bull or stag. In either case a male will answer and will gradually come right up to the sportsman believing him to be a possible mate or a probable antagonist. Every form of big game hunting is a modification of one of these principal methods; the next consideration is that of the distribution of the game fields of the world, which can be dealt with best by continents.

EUROPE

Before 1914 there were two principal hunting fields for big game in Europe proper, Russia and Scandinavia. The conditions in the latter area which comprises the countries of Norway and Sweden

do not differ materially from those prevailing before the war. The game to be found includes reindeer, red deer, European elk and brown bear (*Ursus Arcturus*). Of these the elk is probably the most important and in Norway is more widely distributed than any other species of big game, its habitat including all the larger continuous areas of coniferous forest. But it is a great wanderer and will on occasions invade districts where it has been previously unknown. This is especially the case with the elk which have in recent years been seen in parts of Finmark, where they have probably penetrated from the neighbouring districts of Finland. The best localities for elk have lately been the districts north of Trondhjem, and further south in Hedemarken, Kristians Amt, Storelvedan, Ytre Rendalen and Gausdal in Gudbrandsdalen. The best heads usually come from the more northern districts. The close season for elk varies, but at present they can be killed from Sept. 10 to Sept. 20. Elk are hunted either by still hunting or with special hounds which run them to bay.

The European reindeer is of the barren-ground type, being smaller in the body than the woodland types of Canada and Alaska and carrying long, slender horns which show less palmaria than those of the American caribou. In former times reindeer were very widely distributed throughout the whole of Scandinavia, but now its range has become much more restricted and it only exists on the mountain plateaux above the timberline, and in summer prefers those mountains where there are plenty of "braes" or snowfields.

Red deer are not very widely distributed, existing only along the western coast of Norway from Buknfiord in the south to Namdalen in the north, and in a few other scattered areas. The only localities where red deer are found in any numbers are the two islands of Tusteren and Hitteren. Bears still exist, but in such small numbers as almost to be negligible from a sporting point of view, although a certain number are killed by peasants annually.

Russia is at present an entirely unknown quantity. Without question much of the big game of central and southern Russia has been exterminated during and after the World War. In northern Russia, however, circumstances have been different. The rolling tundras and dense forests, mostly devoid of human habitation, have been little affected by the great upheaval, and it is more than possible that some of the best European hunting grounds of the future may lie in northern Russia and Siberia. From Scandinavia to the eastern coast of Siberia, elk and reindeer are to be found. Further north in the tundras reindeer only are to be found. These tundras consist of open, undulating country covered with heather and lichens, interspersed with bogs, while here and there are to be seen scattered clumps of silver birch. a country, in fact, which is very like some of the northern deer forests of Scotland. Reindeer exist everywhere on these tundras and they are particularly common in the Kola and Yalmal peninsulas and the island of Novaya Zemlya.

Other species of game to be found are lynx and bear, both of which are very plentiful, while wolves are ubiquitous and follow the elk. These wolves, it should be noted, are the big grey timber wolves. Polar bears are fairly common in the northern parts of Novaya Zemlya and walrus may sometimes be encountered on the ice floes. The White Straits are frozen from Christmas to May, while the whole of the Arctic Ocean and Kara Sea are closed with ice from November to May, and are liable to further blocks from ice during periods of northerly winds even later on in the spring.

Central Europe suffered a similar fate to that of central and southern Russia, and the reserved forests which formerly held magnificent red deer, brown bear and roe buck have been sadly depleted of game. In the Carpathians game still exists in considerable numbers. Chamois and red deer both run large in these mountains and it is probable that better heads are to be found here than anywhere else in Europe. Similarly Tirol has been less affected than the lower levels. Chamois are to be found in the Alps in fair numbers, but it must be remembered that all the best districts are preserved. In Spain proper the conditions are the same, and the travelling sportsman would stand no chance of sport without influential friends or exceptional letters of introduction. The big game of Spain are brown bear, red deer, chamois

and Spanish ibex. Bear are very scarce and are confined almost entirely to the mountains of the north, the Pyrenees and Cantabrian mountains. Red deer are somewhat local but they exist in the forests of the Sierra Morena and Andalusia. Although not plentiful, chamois or "Izard" exist in the Pyrenees and Cantabrian mountains. They are somewhat smaller than the chamois of Tirol, both in size of bodies and heads. The Spanish ibex, however, is a magnificent creature but is very strictly preserved. Formerly it used to be found in almost all the mountains of Spain from the Pyrenees to the Mediterranean, but it was so heavily hunted and shot that it became nearly extinct. The most rigid preservation was then introduced with the pleasing result that this grand animal has increased considerably. In the Pyrenees it is found only in one valley, the Val d'Arazas, which is the private property of H.M. the King of Spain and is regarded as a sort of national park. The horns of the Spanish ibex are quite unlike those of any other of the goat tribe, more resembling those of the East Caucasian Tur, than any other.

The chamois of the Pyrenees is one of the only two specimens of European big game which can give the sportsman who is unable to afford the rent of a special shoot, or forest, much chance; the quarry is one which will exercise all his stalking skill and as much hard work as the veriest glutton for exercise can desire. With the exception of the Val d'Arazas, to which reference has already been made, the shooting of the Pyrenees is open to the public for all practical purposes, but a passport both for France and Spain must be obtained. Chamois are by no means common although they are to be found in certain localities.

The other European animal which offers a chance of big game hunting to the sportsman of moderate means is the Sardinian Moufflon. This handsome wild sheep also exists in Corsica, where it had become almost extinct in 1914, but happily it increased during the war and at present it is strictly preserved by the French Government. In Sardinia moufflon shooting is legally open only for one month of the year, normally September, but the game laws are disregarded by the local inhabitants and it would appear to be but a matter of time before the Sardinian moufflon is extinct. These wild sheep at present inhabit the higher mountains, especially the Gennargentu mountains, and good heads may still be obtained although they are becoming more scarce every year.

Useful books dealing with big game hunting in Europe are: Abel Chapman, *Wild Spain and Wild Norway*; E. N. Buxton, *Short Stalks*; and H. P. Highton, *Shooting Trips in Europe and Algeria*.

ASIA

Asia offers greater variations both in climate and physical features than any other continent and although its big game may not be quite so numerous either in species or actual numbers as those of Africa it undoubtedly offers attractions to the big game hunter with an exploring turn of mind which can be equalled in no other part of the world. Beginning in the west moufflon, similar to the Sardinian species but larger, are to be found in the mountains of Asia Minor, while the Caucasus still provides some of the most difficult yet splendid sport in the world. In the higher ranges there is that fine wild goat, the West Caucasian tur, which in the east gives way to the East Caucasian tur, an animal which carries horns very similar to the Himalayan burrel, but which has a short beard and is a true goat with all the characteristic smell of that species. In the wooded valleys may be found the maral, a magnificent specimen of the red deer species almost as large as the American wapiti, while it is just possible that the aurochs is not yet extinct. Then the *pasang*, or Persian wild goat (*Capra aegagrus*), extends right through the Caucasus from the mountains of Asia Minor, and onwards throughout the ranges of northern Persia down to Baluchistan and the hills on the Indian frontier in Sind, where it is known as the Sind ibex.

Persia itself is full of opportunities and is as yet little known from the big game hunter's point of view. Tiger exist in the low lying forests to the south of the Caspian sea and probably further east as well, while the maral of the Caucasus extends well into Persia. The mountain ranges hold at least one variety of wild

sheep which is very similar to the Indian orial, but slightly larger in body and with very much finer heads, and the plains carry several varieties of gazelle. Leopard are common in many parts. Mesopotamia and Palestine offer few attractions, although gazelle are found in the deserts of the former, but Arabia is a *terra incognita*. A species of ibex inhabits the mountains of the Sinaitic peninsula, and possibly extends further inland, while specimens of the Arabian oryx can be obtained from Aden. The Arabian thar inhabits the mountains of Oman and the desert holds gazelle.

Returning to Persia it will be seen that the mountain ranges of this country run eastwards through Afghanistan to India where they increase in height and form the range known as the Hindu Kush. This system extends again to the north and east where it merges into the Karakorum, the range in which is K₂, the second highest mountain in the world, and which continues eastward until it unites with the Kuen Lun Range, that great northern buttress of the Tibetan plateau. North of the Hindu Kush lie the Pamirs, and north of these and parallel to the vast chain of mountain systems already mentioned are the Tian Shan mountains. Yet further north and still parallel are the Altai mountains, and north of these are the Siberian steppes. It will accordingly be seen that there are three huge principal mountain systems of Central Asia, all running approximately east and west, with lower lying levels in between them, although in the centre the wide extent of the Pamir plateau forms a mighty backbone from which the other systems extend.

The whole of this vast area is a wonderful hunting ground. Wild sheep are to be found in the higher ranges which carry heads with wide sweeping horns. Of these the *Ovis poli* of the Pamirs is probably the best known, and this species certainly carries the longest horns, but they are not so massive as those of the *Ovis karakorum* of the Tian Shan, or of the *Ovis ammon* of the Altai, which has the most massive horns of all. The range of these central Asiatic wild sheep is large, extending right through Manchuria to Kamchatka, and throughout the mountains and hills of Manchuria and northern China different species and sub-species exist. Southwards, on the plateau of Tibet, they are represented by the *Ovis ammon hodgsoni*, the "ammon" of the Indian sportsman and the "nyan" of the Tibetans. Ibex range from the northern bank of the river Sutlej through the Himalayas, Karakorum and Pamirs, to the Tian Shan, the heads getting bigger as one travels north, the biggest heads of all being found in the Tian Shan.

China itself is little known. In the mountains of the north wild sheep are found, and it is certain that tiger extend throughout the forests of eastern China from Manchuria to the extreme south. There are, in fact, strong grounds for belief that Manchuria is the real home of the tiger which has extended its range southwards in comparatively recent times. At birth tiger cubs are woolly, indicating a natural protection against cold, and although tigers are found in the hottest jungles of India they dislike heat and their pads will blister when they are forced across open ground in the hot weather. The tiger is common throughout China and extends throughout Cochin China and Siam to Burma, India, the Malay States and Sumatra. In south-east China the forests and cultivation give way to higher altitudes which culminate finally in a mountain range which forms the eastern border of the Tibetan massif. Here are to be found typical game of southern Tibet, the burrhel and the uncouth takin. Apart from tiger Cochin China holds leopard and is probably the eastern outpost of the Asiatic elephant, gaur and rhinoceros. These animals all exist in Siam and here, too, may be found the curious Schomburgk's deer with its widely spreading and many pointed antlers, and a small representative of the Indian sambhur. This grand deer seems to have India as its real home, for it is in this country that it attains to the biggest size both of body and horn, but it has a very wide habitat, being found throughout the Malay Peninsula, Sumatra, Java and Borneo as well as in Ceylon.

Between the Kuen Lun Mountains on the north and Burma, Siam and Cochin China on the south lies the Tibetan plateau, the highest and most extensive plateau in the world. Only one

animal seems to be almost ubiquitous throughout Tibet, and that is the burrhel, or blue wild sheep of the Himalayas, but whose real home is undoubtedly Tibet; it is regarded by some naturalists as the connecting link between the sheep and goats. Vast herds of Tibetan antelope roam over the Chang Tang, the desert of northern Tibet which has a mean altitude of nearly 17,000 feet, and here, too, are to be found herds of wild yak. Further south the *Ovis ammon hodgsoni* and Tibetan gazelle may be obtained, while in the lower districts to the east of Lhasa there are forests which hold Thorold's deer, a large deer very few specimens of which have ever been obtained by European sportsmen. There is also a small bluish bear of Tibet, but very little is known of its habitat. Wolves are numerous, and in the west, bordering on the Himalayas, the snow leopard and Tibetan lynx exist but are rarely encountered.

The Himalayas, the greatest mountain system in the world, form a natural barrier between the lofty desolation of Tibet and the low lying fertile plains of India. The Himalayas themselves provide magnificent stalking, the quarry being, in addition to those Tibetan animals already mentioned, ibex, thar, markhor and shapoo (a wild sheep identical with the orial), while other game animals are goral, serow and two species of bear, one black and one brown, which latter exists only in the higher ranges near the snow line and is a variety of the brown bear of Europe. In the western Himalayas, in Kashmir territory, may be obtained specimens of the Kashmir stag, a deer very similar to, but larger than, the red deer of Scotland, while in the east there is an isolated "pocket" of territory in the Chumbi valley which is the home of a still larger stag, the Shou.

India proper contains the oldest and best known hunting grounds of all. Sportsmen had been accustomed to shooting tigers long before any big game hunter had set foot in Africa. And on the whole conditions have changed little during the past hundred years. The game fields of old are game fields yet: they have shrunk in size and the numbers of animals they hold: that is all. There are no vast areas where game formally teemed and which are now denuded of animal life, and in this respect India is different from other countries. The explanation lies in the fact that the climate renders it an impossible country for the white man to colonise and so the denizens of the Indian jungles have had the chance of existing without the menace of the advance of settlers as has been the case in America and many parts of Africa. The principal game fields are the Terai, a huge belt of tropical jungle which runs along the foot of the Himalayas from the river Jumna to Assam and which holds tiger, elephant, rhinoceros, sloth and black Himalayan bear, sambhur, cheetah, swamp deer and other smaller varieties; the jungles of Central India and the Central Provinces in which tiger, gaur (commonly called the "bison"), sambhur and sloth bear are the most important big game; the damp and intensely thick jungles of southern India, including the Mysore plateau, where elephant, gaur and tiger are abundant, and in the Nilgiri Hills there is a species of wild goat locally known as the "ibex" which is really a variety of tahr. Assam and the Sunderbunds, the semi-flooded delta of the Ganges, are the home of the buffalo, which was also common at one time in the Central Provinces, but which is now almost extinct in that district, and Burma is the best ground for elephant, gaur and tsine, an animal akin to the gaur. Leopard abound in all the areas mentioned while the Indian antelope, or black buck, and gazelle exist in large numbers all over the plains, especially in the deserts of Bikanir and the Punjab.

Probably the best sport is to be obtained in the dependent Indian States, but permission to shoot in these is only gained by special invitation and the visiting sportsman would stand no chance of getting such without exceptional influence. All the jungles of British India proper are controlled by the Imperial Forest Service of India and are divided up into blocks, which are let out to sportsmen for a limited period. The total number of animals which can be killed in each block *per annum* is strictly limited and the blocks are allotted to applicants according to priority of asking. In India there are no firms or individuals who make a business of conducting visiting sportsmen on an extended

hunting tour as is the case in America or East Africa, and big game hunters who visit India must be prepared to make their own arrangements and take their chance with those British officers of the army and different civilian services who spend the greater part of their lives in administering the land. The big game of Ceylon is very similar to that of India except that tiger do not exist in the island and all the horned or antlered game carry very much smaller heads, while the elephants are almost invariably tuskless. Sumatra probably offers the wealthy hunter better opportunities for obtaining specimens of Asiatic elephant, gaur, rhinoceros and possibly tiger, than does India proper. A large launch is essential and such can be hired locally.

Many books have been published dealing with big game hunting in Asia but the following should provide the information necessary: R. L. Kennion, *By Mountain Lake and Stream* (Persia); T. and K. Roosevelt, *East of the Sun and West of the Moon* (Central Asia); G. Burrard, *Big Game Hunting in the Himalayas and Tibet*; R. L. Kennion, *Sport and Life in the Further Himalayas*; A. A. Dunbar-Brander, *The Wild Animals of Central India*; A. E. Stewart, *Tiger and other Game*; J. W. Best, *Shikar Notes* (Central Provinces of India); G. P. Sanderson, *Thirteen Years among the Wild Beasts of India* (Southern India); Fletcher, *Sport in the Nilgiris and Wynnad*, vol. ii. of *Big Game Hunting of the Badminton Library*; *The Indian Field Shikar Book*; G. P. Evans, *Big Game Hunting in Upper Burma*; Forsyth, *Highlands of Central India*; H. G. C. Swayne, *Through the Highlands of Siberia*; E. Demidoff, *A shooting Trip to Kamchatka*.

AFRICA

Although the game fields of the African continent were the last to be discovered they have suffered more than those of any other part of the world, except some parts of North America, from the attacks of the white man. Such attacks, however, have not been delivered by the man who shot for sport, and if sport alone had been the object of pursuit it is doubtful whether the numbers of game would have decreased very materially. In South Africa the Dutch settlers must take the responsibility for the complete extinction of such species as the quagga and the general extermination of game from the greater part of the country which lies to the south of the Limpopo. These settlers shot for the sake of meat and hides, and wherever commercialism enters into the question the fate of wild game is sealed. Similarly the early elephant hunters had much for which to answer. But shooting alone has not been responsible for the elimination of big game from huge areas of Africa. Colonization by different nationalities of European settlers drove the wild animals into unsuitable country, just as it did in America, and it is this advance of civilisation which is really the most serious menace to the *fauna* of Africa. There are, however, gigantic tracts of country quite unsuitable for colonization by white settlers and in such the game should flourish for many years to come, protected as it now is by efficient game laws in most parts of the continent.

In the first place it must be realized that the real wealth of Africa as far as big game is concerned lies in its wonderful variety of antelopes and gazelles. There are over 60 different species. The next interesting point is that no specimen of the deer tribe seems to be indigenous in the whole of Africa. It is true that a few red deer do exist in northern Africa in the neighbourhood of Tunis, but it is probable that these were either imported or else are the descendants of some which migrated from Spain before the formation of the Straits of Gibraltar. Africa shares with Asia the boast of rhinoceros and elephant, but both the African varieties of rhinoceros (black and white) are as different from any variety of Asiatic rhinoceros as is the African elephant from the Indian. The giraffe and okapi are quite distinctive and peculiar to Africa, while the African buffalo, with all its varieties, is as distinctive as is the African elephant. The leopard is distributed throughout the continent and is similar to the Asiatic species although an experienced sportsman can usually detect the difference in the skins. The lion, extinct in Mesopotamia, Palestine and Arabia, and driven into one small corner of India, reigns supreme among the wild creatures throughout the whole of Africa from Morocco in the north to Zululand in the south, and from Somaliland in the east to the Gold Coast in the West.

The most accessible district of all is the Sudan which offers a

great variety of hunting grounds. On the east the Red Sea Hills hold ibex, while the deserts of Kordofan and Dongola provide gazelles, oryx and the elusive addax, as well as Barbary sheep in the barren hills. But the chief hunting grounds of the Sudan lie in the south up the Blue and White Niles. There is a big game reserve in the valley of the Blue Nile, but plenty of excellent ground exists, although the upper courses of the White Nile, notably the Bahr-el-Ghazal, will probably attract the collector of rare varieties as here may be obtained specimens of the giant eland (Lord Derby's) and the white rhinoceros, an animal which was once common in South Africa but is now unknown except in the southern Sudan, Northern Congo and Uganda. Elephants and buffalo are both common but the tusks of the former and horns of the latter are not big in the Sudan.

Just as the Sudan is the nearest of the African big game fields, so Kenya is the most popular. Game may be seen in numbers to be encountered nowhere else in Africa in spite of the fact that the herds are not nearly so large or numerous as they were. Every kind of country and climate is met with in Kenya and each has its own *fauna*. Starting from the Indian Ocean the first district is the coast belt, where game is plentiful but not so easily obtained as in other parts. Porters are the best form of transport and the bag should include elephant, buffalo, rhino, eland, lion, hushbuck and some of the smaller antelopes. The next and by far the most popular district is the highlands which consist of great rolling plains interspersed with patches of bush and situated at an elevation of from 4,500 to 7,000ft., in places reaching 9,000ft. A great part of this area has been settled by Europeans but nearly 11,000,000 acres are permanently reserved for the Masai tribe. The eastern half of this area is a game reserve but the western half is the most popular hunting ground, and here may be obtained specimens of almost every variety of East African game. But a very large portion of Kenya is taken up by desert which lies to the north of the Highlands. The game of this desert is confined to oryx, Grévy's zebra, dikdik and Grant's gazelle, which gives place to Sommerring's gazelle in Jubaland.

The real tropical African country is not found much in Kenya but covers an extensive part of Tanganyika, where there is nearly as much possibility of varied sport as in Kenya. Here one comes to the land of the sable antelope, which extends right down through Nyasaland, Northern and Southern Rhodesia to the frontiers of the Kalahari, but for really big sable antelope Angola is the best district. Rhodesia, both north and south, is a fine hunting ground and offers a chance of big kudu and roan antelope. Portuguese East Africa is heavily poached, but in the big swamps round the mouth of the Zambesi buffalo roam in great herds. South Africa has now little to show in the way of big game, although Zululand is probably still the best chance for nyala and the Kalahari Desert is the only place where gemsbuck exists.

The West Coast holds plenty of game but not nearly in such profusion as the East, and this fact combined with the doubtful climate prevent its attracting sportsmen in numbers. Further the heads of animals run smaller as a rule than they do in the east, while elephants carry lighter tusks. The West African buffalo, or bush cow, is, however, a distinctive type which is found nowhere else. The immense tracts of the French and Belgian Congo are seldom visited by sportsmen other than professional elephant hunters, but bordering on the eastern boundary of the Belgian Congo lies Uganda which is the district, *par excellence* for elephant and buffalo, as well as that shy and retiring water antelope, the situtanga. To the north of the Congo extends the great Sahara Desert, the home of gazelles, but in the hills of Morocco and Algiers, the sportsman who has not time for a long journey has a chance of Barbary sheep.

Useful books of reference dealing with African big game hunting include H. C. Maydon, *Simen, its Heights and Abysses* (Abyssinia); H. G. C. Swayne, *Seventeen Trips through Somaliland*; W. D. M. Bell, *Wanderings of an Elephant Hunter*; Abel Chapman, *Savage Sudan*; W. B. Cotton, *Sport in the Eastern Sudan*; Sir Samuel Baker, *Nile Tributaries of Abyssinia* (Blue Nile); A. B. Percival, *A Game Ranger's Notebook*; F. C. Selous, *A Hunter's Wanderings in Africa, Sunshine and Storm in Rhodesia*; H. A. Bryden, *Kloof and Karroo*; P. H. G. Powell Cotton, *Travel and Adventure in the Congo*; J. C. B. Statham, *Through Angola, The South and East African Year Book and Guide*.

NORTH AMERICA

Just as Africa is the home of the antelopes so North America may be described as the home of the deer. The moose, wapiti (known as "elk"), caribou (both woodland and barren ground varieties), mule deer, white tail and black tail being among the varieties to be found. Other game animals are the grizzly and black bears, several varieties of big horn sheep, Rocky Mountain goat and in the extreme north polar bear. The pronghorn antelope which is a peculiarly interesting animal in that it forms the connecting link between the deer and antelope (having regular horns, as opposed to antlers, which it sheds annually) was at one time extraordinarily common and roamed the prairies in great herds, but it is now confined to a few districts in the farther west and to that great national game reserve, the Yellowstone park. Here also may be seen the remnants of the stupendous herds of bison, or American "buffalo", which formerly darkened the prairie and which suffered almost complete extinction.

At the beginning of the 20th century Newfoundland provided the finest caribou shooting to be obtained, the heads of the woodland variety being remarkable for their size and number of points. But they were slaughtered during their annual migrations to such an extent that they were threatened with extinction and at present killing of caribou in Newfoundland is prohibited. The chief game fields of North America now consist of New Brunswick, where moose are fairly plentiful but little else, and the country from the east of the Rocky mountains to the Pacific coast right up into Alaska. Here all the varieties of North American big game may be obtained. Wapiti do not range much to the north of British Columbia, but moose are especially plentiful, the biggest heads coming from Alaska, while there is an exceptionally large variety of grizzly bear which inhabits Kodiak Island off Alaska. The wild sheep are akin to the various Asiatic varieties found in Mongolia and Kamchatka.

Useful books in North American big game hunting are: C. R. E. Radclyffe, *Big Game Shooting in Alaska*; and Bryan Williams, *Game Trails in British Columbia*.

OTHER GAME FIELDS

South America has little in the way of attractions to the big game hunter, the jaguar being the only animal worthy of pursuit, and this leaves Australia as the only continent which has not been considered. The only indigenous big game of Australia is the kangaroo which is scarcely an animal for the sportsman's rifle, but in the Northern Territories there are herds of buffalo, the descendants of domesticated animals which escaped into the bush and have been completely wild for many generations. Some of these bulls carry quite good heads.

New Zealand, however, is on a very different footing and is a country of peculiar interest in that all its game has been imported. These experiments in importation have been most successful with the result that for many years magnificent red deer heads have been obtained, and at the present time the following animals seem to have become acclimatised: red deer; American moose and wapiti; chamois; Indian sambhur, cheetah, thar and burrhel; mule deer. It is highly probable, therefore, that in a few years' time New Zealand will be able to offer as fine a variety of good heads as any other country of the same size in the world.

See T. E. Donne, *Red Deer Stalking in New Zealand*; and *The Game Animals of New Zealand*.

General Information.—One of the most important steps in the planning of an expedition after big game is to ascertain the best time of year for hunting. Quite apart from the question of health, should the sportsman visit the country at an unfavourable season he may stand but a small chance of sport because some peculiar local conditions, such as high grass, may prevent him from seeing anything. Another factor is water: as a rule this is fairly plentiful in any district where game exists in abundance, but at some seasons of the year it may be very scarce, and only exist in certain localities. Information on these points will always be given gladly by the Game Department of the country in which it is proposed to hunt, and the following further information should also be obtained: (1) what stores and equipment can be

obtained locally; (2) what means of transport is generally used between the proposed base and the actual shooting grounds; (3) whether this transport is easily obtained, and how; (4) whether any trackers or native hunters are available. Good maps of the country are another essential item.

The question of the most suitable battery is largely a matter of personal preference built up on experience, but generally speaking the best weapon for stalking is a rifle of the modern "magnum" small bore type which develops a very high muzzle velocity and so gives a flat trajectory, thus eliminating the difficulties of judging distance. It is always a mistake, however, to select a rifle which does not fire a fairly heavy bullet, as very light bullets are too liable merely to wound, and 150 grains is a fairly safe minimum weight. For dangerous game which is shot at close quarters the tyro will be well advised to use a heavy double cordite rifle of a calibre of about .470. There are many experienced hunters who use nothing but small bores, but the beginner can adopt such methods when he has gained experience for himself.

Useful books dealing with big game hunting generally are: G. Burrard, *Notes on Sporting Rifles*; Rowland Ward, *Records of Big Game*; Sir S. Baker, *Wild Beasts and their Ways*; Badminton Library *Big Game* (Two Volumes); Rowland Ward, *The Sportsman's Handbook*. (G. Bu.)

BIGGLESWADE, urban district, Bedfordshire, England, 41 m. N. by W. of London by the L.N.E. railway. Pop. (1921) 5,395. It lies on the east bank of the Ivel, a tributary of the Ouse, on a plain in which vegetables are largely grown for London markets. Biggleswade (Bichelswade, Beckleswade, Bickleswade) is an ancient borough by prescription. The borough court was held by the lord of the manor. At the time of Edward the Confessor, Archbishop Stigand owned the manor. Henry I. granted it to the bishop of Lincoln, under whose protection the borough evidently grew up. In 1547 the bishop surrendered his rights to the king, and in the 17th century Biggleswade formed part of the jointure of the queens of England. Annual fairs were held here from early times. Biggleswade was formerly engaged in straw-plaiting and lace manufacture.

BIG HOLE BATTLE FIELD, a tract five acres in extent in southwestern Montana, U.S.A., set apart in 1910 as a National monument. It is the scene of a battle which was won on Aug. 9, 1877, by a small force of United States troops over a large number of Nez Perce Indians. The reservation is administered by the War department.

BIGHORN, the common name of the Rocky Mountain sheep (*Ovis cervina*), so called from the size of the horns in the male. The female bears shorter, ribbed horns. The bighorn is the only wild sheep indigenous to the New World, where it was formerly found from Mexico to Alaska in the mountainous districts, it is now extremely rare south of Montana, except in game preserves. The bighorn is gregarious and displays great activity and wariness. The horns of the ram may measure 42 in. round the curve. There are several varieties, sometimes separated as distinct species.

BIGHT, a nautical term for the loop or bent part of a rope, as distinguished from the ends; it is used as a geographical term for a slightly receding bay between two distant headlands, e.g., the Bight of Benin, the Great Bight of Australia. The name is occasionally used for any slight bend or curve as a geographical feature, e.g., the corner or recess of a bay, the bend of a river.

BIGNON, JÉRÔME (1589–1656), French lawyer, made his reputation by his *Chorographie ou description de la Terre Sainte*, (1600). Henry IV. made him tutor to the dauphin (Louis XIII.), under whose reign he held important legal offices. His other principal works were *Traité sommaire de l'élection du pape* (1605), and an edition of the *Formulae* of the jurist Marculf.

BIGNON, LOUIS PIERRE ÉDOUARD, BARON (1771–1841), French diplomatist and historian, was born on Jan. 3 1771, and died at Paris, Jan. 5 1841. As minister-plenipotentiary at Cassel, between the years 1804 and 1806, he took a prominent share in the formation of the confederation of the Rhine; and after the battle of Jena he returned to Prussia as administrator of the public domains and finances. He filled a similar function

in Austria in 1809 after the battle of Wagram. At the end of 1810 he became French resident at Warsaw. After Waterloo, as minister of foreign affairs under the executive commission, it was he who signed the convention of July 3 1815, by which Paris was handed over to the allies. Bignon did not re-enter public life until 1817, when he was elected to the chamber of deputies, in which he sat until 1830, consistent in his opposition to the reactionary policy of successive governments. He published attacks on the policy of the continental allies, two of his works attracting special attention, *Du Congrès de Troppau ou Examen des prétentions des monarchies absolues à l'égard de la monarchie constitutionnelle de Naples* (1821), and *Les Cabinets et les peuples depuis 1815 jusqu'à la fin de 1822* (1822).

He was for a few weeks minister of foreign affairs in the first government of Louis Philippe, and again for a few weeks minister of public instruction. Elected deputy in 1831 and member of the chamber of peers in 1839, he devoted himself to his great work, the *Histoire de France sous Napoleon* (10 vols. 1829-38, then 4 vols., 1847-50).

See Mignet, *Notice historique sur la vie et les ouvrages de M. Bignon* (1848).

BIGOD, HUGH (d. 1177), earl of Norfolk, was the second son of Roger Bigod (d. 1107), the founder of the English family of this name. Hugh inherited large estates in East Anglia on the death of his brother William in 1120, and enjoyed the favour of Henry I. At first a supporter of Stephen during this king's struggle with the empress Matilda, Hugh was rewarded with the earldom of Norfolk before 1141. After having fought for the king at the battle of Lincoln the earl deserted him, assumed a position of armed neutrality during the general anarchy, and then assisted Henry II. in his efforts to obtain the throne. This king confirmed him in the possession of his earldom; but becoming restless under the rule of law initiated by Henry, he participated in the revolt of 1173, which so far as England was concerned centred round his possession. Though defeated and compelled to surrender his castle, Bigod kept his lands and his earldom, and lived at peace with Henry II. until his death, which probably took place in Palestine.

His son ROGER (d. 1221), who succeeded to the earldom of Norfolk, was confirmed in his earldom and other honours by Richard I., after he had fallen under the displeasure of Henry II. He took part in the negotiations for the release of Richard from prison, and after the king's return to England became justiciar. The earl was one of the leaders of the baronial party which obtained John's assent to Magna Carta, and his name appears among the signatories to this document.

Roger was succeeded as 3rd earl by his son, Hugh, who died in 1225, leaving a son, ROGER (d. 1270), who became 4th earl of Norfolk. Through his mother, Matilda, a daughter of William Marshal, earl of Pembroke, Roger obtained the office of marshal of England in 1246. He was prominent among the barons who wrested the control of the government from the hands of Henry III, and assisted Simon de Montfort. The earl married Isabella, daughter of William the Lion, king of Scotland, but left no sons.

Hugh, the 3rd earl, left a younger son, HUGH (d. 1266), who was chief justiciar of England from 1258 to 1260, and who fought for Henry III. at the battle of Lewes. The latter's son, ROGER, succeeded his uncle Roger as 5th earl of Norfolk in 1270. This earl was the hero of a famous altercation with Edward I. in 1297, which arose out of the king's command that Bigod should serve against the king of France in Gascony, while he went to Flanders. The earl asserted that by the tenure of his lands he was only compelled to serve across the seas in the company of the king himself, whereupon Edward said, "By God, earl, you shall either go or hang," to which Bigod replied, "By the same oath, O king, I will neither go nor hang." The earl gained his point, and after Edward had left for France he and Humphrey Bohun, earl of Hereford, prevented the collection of an aid for the war and forced Edward to confirm the charters in this year and again in 1301. The earl died without issue in December 1306, when his title became extinct and his estates reverted to the crown. The Bigods held the hereditary office of steward (*dapifer*) of the royal

household, and their chief castle was at Framlingham in Suffolk.

BIBLIOGRAPHY.—See J. R. Planche, "The Earls of East Anglia" (*Brit. Arch. Ass.*, vol. xxi., 1865); G. E. C(okayne), *Complete Peerage*, vol. vi. (1895); and W. Stubbs, *Constitutional History*, vols. i. and ii. (1896-97).

BIGOT, one obstinately and intolerantly holding particular opinions, generally religious. The early meaning of the word in English, at the end of the 16th century, was that of a religious hypocrite. It was applied in French, in the 12th century, to certain tribes of Southern Gaul, and, in an abusive sense, to the Normans. The meaning changed in French to that of "religious hypocrite" through the application, in the feminine *bigote*, to the members of the religious sisterhoods called Beguines (*q.v.*).

BIG RAPIDS, a city of Michigan, U.S.A., on the Muskegon river, 56m. north by east of Grand Rapids; the county seat of Mecosta county, which contains 90 lakes. It is served by the Pennsylvania and the Pere Marquette railways. The population in 1920 was 4,558. The principal manufactures are veneer, lumber, furniture, automatic machinery and tools. Fox-farming is a growing industry in the surrounding country. A State trout hatchery is situated at Paris, 6m. away. Big Rapids was settled in 1854, laid out in 1859, and chartered as a city in 1869. It owes its name to the falls of the Muskegon, which drop 16ft. within the city limits, furnishing a source of abundant hydro-electric power.

BIGSBY, JOHN JEREMIAH (1792-1881), English geologist and physician, the son of Dr. John Bigsby, was born at Nottingham on Aug. 14, 1792. Educated at Edinburgh, where he took the degree of M.D., he joined the army medical service, and then, in 1817, was stationed at the Cape of Good Hope. In 1822 he was appointed British secretary and medical officer to the Boundary Commission, and carried out extensive and important geological researches, contributing papers to the *American Journal of Science* and other scientific journals. He returned to England in 1827. During the last 20 years of his long life he was continually at work preparing tabulated lists of the fossils of the Palaeozoic rocks. His *Thesaurus Siluricus* was published with the aid of the Royal Society in 1868; and the *Thesaurus Devonico-Carboniferus* in 1878. In 1877 he founded the Bigsby medal to be awarded by the Geological Society of London. He died in London on Feb. 10, 1881.

BIG SPRING, a city of western Texas, U.S.A., on Federal highways 80 and 385, Girauds Creek, and the Texas and Pacific railway; the county seat of Howard county. The population was 4,273 in 1920 (91% native white). It is a division headquarters of the railroad, which has offices, round-houses and shops employing 500 men. Stock farming is the principal occupation of the region, and large shipments of cattle are made. An experiment station of the department of agriculture is situated there. There are large springs and oil wells in the vicinity.

BIHARI LANGUAGE (properly *Bihārī*), the most western speech of the eastern group of modern Indo-Aryan languages "Bihārī" means the language spoken in the province of "Bihār." To the west it extends over the province of Agra so far as the longitude of Benares, and to the south it covers nearly the whole of the province of Chota Nagpur. It is also the language of the inhabitants of the neighbouring Tarai districts of Nepal (see INDO-ARYAN LANGUAGES). While an outer language, it shows points of contact with the intermediate ones. As regards *s*, the Māgadhi Prakrit pronounced it as *ś*, like the *sh* in "shin." The Prakrits of the West preserved its dental sound, like that of the *s* in "sin." Here Bengali and Eastern Hindi exactly represent the ancient state of affairs. The former has the *ś*-sound and the latter the *s*-sound. At the present day Bihari pronounces its *s*'s as clearly as in the West. The pronunciation of *s* is a literal shibboleth between Bengal and Upper India. For centuries Bihar has been connected politically with the West, and has rid itself of the typical pronunciation of the East. On the other hand, in the Kaithi character, *s* is always written *ś*. In the declension of nouns, Bihari follows Bengali more closely than Eastern Hindi, and its conjugation is based on the principles which obtain in the former language.

Bihari has three main dialects, which fall into two divisions, an eastern and a western. The eastern division includes *Maithili* or *Tirhutīā* and *Magahi*. *Magahi* is the modern representative of the purest Māgadhī Prakrit. It is nearly related to Maithili, but it is quite uncultivated and has no literature. Maithili is the dialect of the old country of *Mithilā* or *Tirhut*, famous from ancient times for its learning. It has retained numerous antiquated forms, and parts of its grammar are extraordinarily complex. It has a small literature. The Bhojpuri dialect has extended south-east into the southern half of Chota Nagpur. It might almost be classed as a separate language, had it any literature worthy of the name.

(Abbreviations: Mth.=Maithili, Mg.=Magahi, Bh.=Bhojpuri, B.=Bihari, Bg.=Bengali, Skr.=Sanskrit, Pr.=Prakrit, Mg.Pr.=Magadhī Prakrit.)

Vocabulary.—*Tatsamas*, or words borrowed in modern times from Sanskrit (see INDO-ARYAN LANGUAGES), are few in number, while all the dialects are replete with honest home-born *tadbhavas*, used both in the literary and in the colloquial language. Very few words are borrowed from Persian, Arabic, or other languages.

Phonetics.—The stress-accent of Bihari follows the usual rules of modern Indo-Aryan vernaculars. As a general statement we may say that Bihari spelling is not fixed, and that there are often many ways of writing, and sometimes two or three ways of pronouncing the same word.

The genius of the Bihari language is adverse to the existence of a long vowel in a *tadbhava* word, when it would occupy a position more than two syllables from the end. This is subject to various subsidiary rules which will be found in the grammars. The principle is a most important one, and, indeed, pervades all Indo-Aryan vernaculars of the present day, but it is carried out with the greatest thoroughness and consistency in Bihari. The whole system of declension and conjugation is subject to it.

Declension.—Bihari has a stronger sense of gender than the other languages of the eastern group. In the modern language the distinction is in the main confined to animate beings, but in the older poetry the system of grammatical, as distinct from sexual, gender is in full swing. Except in the case of the interrogative pronoun, there is no neuter gender—words which in Skr. and Pr. were neuter being generally, but not always, treated as masculine. The plural can everywhere be formed by the addition of some noun of multitude to the singular.

Cases are usually formed, as elsewhere, by suffixing postpositions to a general oblique case, usually the same as the nominative. There is no case of the agent, as in Hindustani; the subject of all tenses of all verbs being always in the nominative.

Every noun can have three forms, a short, a long, and a redundant. The short form is sometimes weak and sometimes strong. Occasionally both weak and strong forms occur for the same word. The long and redundant forms are mainly used in conversation. They are familiar and often contemptuous. Sometimes they give a definite force to the word as *ghorawā*, the horse. In the feminine they are much used to form diminutives.

The singulars of the personal pronouns have fallen into disuse. The plurals are used politely for the singulars, and new forms are made from these old plurals to make new plurals. The old singulars survive in poetry and in the speech of villagers, but even here the nominative has disappeared and new nominatives have been formed from the oblique bases. All the pronouns have numerous optional forms.

Conjugation in Maithili and Magahi.—It is in the conjugation of the verb that the amazing complexity of the Mth. and Mg. grammars appears. In all three dialects the verb makes little or no distinction of number, but instead there is a distinction between non-honorific and honorific forms. In Mth. and Mg. this distinction applies not only to the subject but also to the object, so that for each person there are, in the first place, four groups of forms, viz.:—

- I. Subject non-honorific, object non-honorific.
- II. Subject honorific, object non-honorific.
- III. Subject non-honorific, object honorific.
- IV. Subject honorific, object honorific.

Forms in which the object is non-honorific may be, as in the case of nouns, short, long or redundant. There are numerous optional forms. Moreover, the feminine gender of the subject introduces new complications. These *minutiae* must be learnt from the regular grammars.

There are numerous irregular verbs. There is a long series of transitive verbs formed from intransitives and of causal verbs formed from transitives. Compound verbs are numerous.

The Bh. conjugation is simple. In the first and second persons the plural is generally employed for the singular, but there is no change in the verb corresponding to the person or honour of the object.

The termination of the present changes in sympathy with the old present to which it is attached. Irregular verbs, the formation of transitive and causal verbs, and the treatment of compound verbs, are on the same lines as in Mth.

Literature.—In all three dialects there are numerous folk-epics transmitted by word of mouth. The only dialect which has any real literature is Maithili. The earliest writer is Vidyapati Thakkura (Bidyapati Thākūr), who lived at the court of Rājā Śiva Śimha of Sugaonā in Tirhut in the 15th century. His fame rests chiefly on his dainty lyrics in Maithili dealing with the loves of Rādhā and Krishna. These have exercised an important influence on the religious history of eastern India. They were adopted and enthusiastically recited by the reformer Caitanya (16th century), and through him became the home-poetry of the Bengali-speaking Lower Provinces. Their language was transformed (we can hardly say translated) into Bengali, and in that shape they have had numerous imitators. A collection of poems by the old Master-singer in their Maithili dress has been published by Grierson in his *Chrestomathy* of that language. The most admired of Vidyapati's successors is Manbōdh Jhā, who died in 1788. He composed a *Haribans*, or poetical life of Krishna, which has great popularity. Many dramas have been composed in Mithila. The fashion is to write the body of the work in Sanskrit and Prakrit, but the songs in Maithili. Among modern writers in the dialect, we may mention Harṣanātha, an elegant lyric poet and author of a drama, entitled *Uṣā-haraṇa*, and Candra Jhā, whose version of the *Rāmāyana* and translation of Vidyapati's Sanskrit *Puruṣa-parīkṣā* are deservedly popular.

BIBLIOGRAPHY.—*The Linguistic Survey of India*, vol. v. part ii. (1903), gives a complete conspectus of Bihari in all its dialects and sub-dialects. See also G. A. Grierson, *Seven Grammars of the Dialects and Sub-dialects of the Bihārī Language*, parts i. to viii. (1883–87—these deal with every form of Bihari except standard Maithili); and S. H. Kellogg, *A Grammar of the Hindi Language, in which are treated High Hindī . . . also the Colloquial Dialects of . . . Bhojpur, Magadha, Maithila, etc.* (2nd ed., London, 1893).

For Maithili, see G. A. Grierson, *An Introduction to the Maithili Language of North Bihār*, containing a *Grammar, Chrestomathy and Vocabulary*; part i. *Grammar* (1881; 2nd ed., 1900), part ii. *Chrestomathy and Vocabulary* (1882). For Vidyapati Thakkura, see J. Beames, "The Early Vaishnava Poets of Bengal," in *Indian Antiquary*, ii. (1873), pp. 37 ff.; the same, "On the Age and Country of Vidyapati," *ibid.*, iv. (1875), pp. 290 ff.; anon. article in the *Banga Darśana*, vol. iv., (1282 B.S.), pp. 75 ff.; Śirādicaraṇa Maitra, *Introduction to Vidyāpatir Padāvalī* (1285 B.S.); G. A. Grierson, *Chrestomathy*, as above; "Vidyapati and his Contemporaries," *Indian Antiquary*, vol. xiv. (1885), pp. 182 ff.; "On some Mediaeval Kings of Mithilā," *ibid.*, vol. xxviii. (1890), pp. 57 ff. A later and more complete collection of Vidyapati's poems (but containing many that are of doubtful origin) is *Vidyāpatir Thākurer Padāvalī* by Nagēndranāth Gupta (Calcutta, 1316 B.C.=A.D. 1909).

For Bhojpuri, see J. Beames, "Notes on the Bhojpuri Dialect of Hindi spoken in Western Bihār," in *Journal of the Royal Asiatic Society*, vol. iii. n.s. 1868, pp. 483 ff.; A. F. R. Hoernle, *A Grammar of the Eastern Hindī compared with the other Gaudian Languages* (here "Eastern Hindī" means "Western Bhojpuri"), (London, 1880); J. R. Reid, *Report on the Settlement Operations in the District of Azamgarh* (Allahabad, 1881), contains, in appendices, full grammar and vocabulary of Western Bhojpuri.

No special works have been written about Magahi.

BIHĀRI-LĀL, the author of the *Sat-saī*, a collection of approximately 700 distichs, perhaps the most celebrated of Hindi poetry. The language is the form of Hindi called *Braj-bhāshā*, the idiom of Mathurā, the poet's home. Most of the verses are amorous utterances of Rādhā and her lover, Krishna. A couplet in the *Sat-saī* states that it was completed in A.D. 1662, although

couplet 705 seems to refer to an event of the year 1665. It is said that Mirzā Jai Singh, for whom the verses were composed, rewarded the poet with a gold piece (16 rupees) for every couplet. Little is known of the author beyond what he himself tells us. He was born in Gwalior, and later settled in Mathurā. The collection very soon became celebrated, and its high position may be judged from the fact that 17 commentators have devoted their efforts to its full interpretation. Many different recensions exist, but the standard is that settled by an assembly of poets under the direction of Prince A'zam Shāh, the third son of the emperor, Aurangzēb (1653-1707), and hence called the A'zam-shāhi; it comprises 726 couplets. The collection has also twice been translated into Sanskrit.

The best-known commentary is that of Lallū-jī-Lāl, entitled the *Lāla-chandrikā*. A critical edition of it has been published by Dr. G. A. Grierson (Calcutta, 1896).

BIISK (Brysk), a town in the Siberian area of the Russian Socialist Federal Soviet Republic, situated at the point where the Ob river is formed by the junction of the Biya and the Katun. Lat. 52° 40' N., long. 85° 40' E. Pop. (1926) 45,574. It has storage plant for butter and eggs and is the terminus of a caravan route from Kobdo in Mongolia. The Ob river is navigable to Biisk, and Siberian merchants dispatch their wool and skins by steamer as soon as the ice melts and in spring form caravans to go to Mongolia, taking with them manufactured goods and lump silver. Chinese brick tea is sometimes used as currency. The rate of exchange of silver and brick tea at Biisk is an interesting index of the relative prosperity of the Siberian area and Mongolia.

BIJAPUR, an ancient city and modern district of British India in the southern division of Bombay. It is a station on the Southern Mahratta railway, 60m. S. of Sholapur. The ancient city was supplied with water by an elaborate underground system of reservoirs and aqueducts, which has been restored in part. The population in 1921 was 32,485. The city used to be the extensive and splendid capital of an independent sovereignty of the same name, but now retains only the vestiges of its former grandeur, though it is now increasing in population, and includes one of the most picturesque collection of ruins in India. The city owed its greatness to Yusuf Adil Shah, the founder of the independent State of Bijapur. It consists of three distinct portions—the citadel, the fort and the remains of the city. The citadel, a mile in circuit, is of great strength and encompassed by a ditch 100yd. wide, formerly supplied with water, but now nearly filled up with rubbish. Within the citadel are the remains of Hindu temples, which prove that Bijapur was an important town in pre-Mohammedan times. The fort, which was completed by Ali Adil Shah in 1566, is surrounded by a wall 6m. in circumference and from 30 to 50ft. high, with massive bastions and a deep moat. Outside the walls are the remains of a vast city, now for the most part in ruins, but affording abundant evidence of the ancient splendour of the place. The Gol Gunbaz, or tomb of Sultan Mohammed Adil Shah, which was built 1626-56 is a square building, surmounted by a great circular dome 198ft. high. The inside area is greater than the Pantheon at Rome. It has been thoroughly restored, and one portion is used as a museum. The Ibrahim Roza, or tomb and mosque of Ibrahim Adil Shah, which took 36 years to build, is exquisitely beautiful. It was completed about 1620. The Gagan Mahal, or ancient audience hall, is in ruins but the archway, about 90ft. high, remains. Through it the last king of Bijapur was brought bound with silver chains, while on a raised platform sat Aurangzeb, the Mogul emperor, who had left Delhi three years previously to conquer the Deccan.

History.—The founder of the Bijapur dynasty, Yusuf Adil Shah, is said to have been a son of the Ottoman sultan Murad II., who went to India, took service under the Bahmani king of the Deccan, and ultimately became a person of great importance at the court of Mahmud II. In 1489 he took advantage of the break-up of the Bahmani power to establish himself as an independent sultan at Bijapur, his dominions including Goa on the west coast. His descendants maintained the prosperity of the State, until the rise of the Mahratta power under Sivaji began to make inroads upon it, and it was exposed to the yet more for-

midable ambition of Shah Jahan. In 1686 the Mogul emperor, Aurangzeb, who as Shah Jahan's general had unsuccessfully besieged the city under Mohammed Adil Shah, took Bijapur and annexed the kingdom to the Delhi empire. The celebrated gun, Malik-i-Maidan, now in the capital, and said to be the largest piece of cast bronze ordnance in the world, was captured from the king of Ahmadnagar by the king of Bijapur about the middle of the 17th century. An inscription on the gun recording that fact was erased by Aurangzeb, who substituted the present inscription stating that he conquered Bijapur in 1686. The city and territory of Bijapur remained annexed to Delhi till 1724, when the nizām established his independence in the Deccan, and included Bijapur within his dominions; but, being defeated by the Peshwa in 1760, he was compelled to purchase peace by its cession to the Mahrattas. Upon the fall of the Peshwa in 1818 Bijapur passed into the hands of the British, and was by them included in the territory assigned to the rajah of Satara. In 1848 the territory of Satara was escheated through the failure of heirs. The city was made the administrative headquarters of the district in 1885.

The district of Bijapur occupies a barren plain, sloping eastward from a string of feudatory Mahratta States to the nizām's dominions. It contains an area of 5,707sq.m., and its population in 1921 was 796,876. The fluctuating numbers of the population reveal the effects of famine. There is very little irrigation in the district. The principal crops are millet, wheat and cotton. There are considerable manufactures of cotton and silk goods and blankets, several factories for ginning and pressing cotton, and a grain and cattle trade. The East Deccan line of the Southern Mahratta railway traverses the district from north to south.

BIJAWAR, a state of Central India, in the Bundelkhand agency. Area, 973 sq.m.; pop. (1921) 111,723. Forests cover nearly half the State, which is believed to be rich in minerals, but lacks transport facilities.

The State takes its name from the chief town, Bijawar (pop. in 1921, 6,133), founded by Bijai Singh, one of the Gond chiefs of Garha Mandla, in the 17th century. It was conquered in the 18th century by Chhatarsal, the founder of Panna, a Rajput of the Bundela clan, whose descendants still hold it. It was confirmed to Ratan Singh in 1811 by the British Government under the usual *sanad*. In 1857 Bhan Pratap Singh helped the British during the Mutiny, being rewarded with certain privileges and a hereditary salute of 11 guns. In 1866 he received the title of maharajah, and the prefix *sawai* in 1877.

BIJNOR, a town and district of British India in the Bareilly division of the United Provinces. The town is about 3m. from the left bank of the Ganges. The population in 1921 was 18,095. There is a large trade in sugar.

The district of Bijnor has an area of 1,874 square miles. The country is mainly a level plain, but the northern part rises towards the Himalayas, the greatest elevation being 1,342ft. above the sea-level. The Koh and Ramganga are the principal rivers, and the Ganges forms its western boundary. In 1921 the population was 740,182. The country is watered in most parts by streams, but a series of small canals has been constructed. Sugar is largely exported.

Of the early history of Bijnor, even after it passed under Mohammedan rule, little is known with any certainty. About 1748 the Rohilla chief, Ali Mohammed, made his first annexations in Bijnor, the rest of which soon fell under the Rohilla domination. The northern districts were granted by Ali Mohammed to Najib Khan, who gradually extended his influence west of the Ganges and at Delhi, receiving the title of Najib-ud-daula and becoming paymaster of the royal forces. For the part played by him in the victory of Panipat he was made wazir of the empire. After his death in 1770 his son, Zabita Khan, was defeated by the Mahrattas, who overran all Rohilkhand. In 1772 the nawab of Oudh made a treaty with the Rohillas, covenanting to expel the Mahrattas in return for a money payment. He carried out his bargain; but the Rohilla chiefs refused to pay. In 1774 the nawab concluded with the Government of Calcutta a treaty of alliance, and he now called upon the British, in accordance with its terms, to supply a brigade to assist him in enforcing his claims

against the Rohillas. This was done; the Rohillas were driven beyond the Ganges, and Bijnor was incorporated in the territories of the nawab, who in 1801 ceded it to the East India company. During the Mutiny of 1857 it was occupied by the nawab of Najibabad, a grandson of Zabita Khan; he held it until April 1858, when he was defeated by the British at Nagina; whereupon British authority was restored.

BIKANER, SIR GANGA SINGH, MAHARAJA OF (1880—), Indian soldier and statesman, succeeded by adoption his elder brother, Dungar Singh, in 1887, as 21st ruler of the State, being invested with full powers in 1898. The first of his many visits to England was made in 1902, when he attended King Edward's coronation, and became A.D.C. to the prince of Wales, an appointment continued by King George. In the World War the Maharaja served in France as a staff officer, and in 1915 in Egypt. In 1917 he was made a member of the Imperial War Conference, and assisted the secretary for India at the Imperial War Cabinet. He represented the Indian States at the Peace Conference, 1919, and the Indian princes at the League of Nations Assembly, Geneva, 1924. It was largely due to his personal influence that the constitution of the Chamber of Princes, as a deliberative, consultative and advisory body, was secured under royal proclamation in 1921.

BIKANER, an Indian state in the Rajputana agency, with an area of 23,315 sq.m., a desolate tract, without a single permanently running stream. It is overspread with undulating sandhills, 20 to 100 ft. above the average level, and so loose that men and quadrupeds stepping off the beaten track sink as if in snow. Two streams, the Katli and Ghaggar, attempt to flow through this dismal region, but are lost in its sands. Water is very scarce, and is raised from wells of from 150 to 340 ft. in depth. A few shallow salt lakes are filled by rain water, but they dry up on the setting in of hot weather, leaving a thick crust of salt on their beds, which is used for commercial and domestic purposes. The Ghaggar canal from the Punjab irrigates 5,000 acres on the northern border; and a magnificent new canal, connected with the Sutlej Valley scheme, has just been opened, which is intended to protect about 1,100 sq.m. of the state. The inhabitants live chiefly by pasturage, rearing camels, horses and sheep. The other industries are leather work, sugar-refining, goldsmith's work, ivory carving, iron, brass, copper, stone masonry, tanning, weaving, dyeing and carpentry. The principal towns are Bikaner, the capital, Churu, Rajgarh, Ratangarh and Reni. In 1921 the population was 659,685. The military force includes a famous Camel Corps, which distinguished itself in China in 1900, and in Egypt during 1914-18. The educational institutions embrace the Dungar Memorial college, a school for the sons of nobles, and a girls' school called after Lady Elgin. The city of Bikaner is surrounded by a stone wall, 6 ft. thick, 15 to 30 ft. high and $3\frac{1}{2}$ m. in circuit, with five gates and three sally-ports. The citadel half a mile north-east of the city, is surrounded by a rampart with bastions. The population in 1921 was 69,410. The Bikaner carpets are famous, and there are also manufactures of fine blankets and sugar-candy. The wealth of the towns in this state is due to their being the ancestral homes of Marwari merchants, who trade all over India and amass great riches, with which they retire to the abodes of their forefathers.

In the 15th century the territory which now forms the state of Bikaner was occupied by Rajput clans, partly Jats, partly Mohammedans. About 465 Bika, a Rathor Rajput, sixth son of Rao Jodha, chief of Marwar, started out to conquer the country. By taking advantage of the rivalries of the clans he succeeded; in 1485 he built the small fort at the capital which still bears his name, and in 1488 began the building of the city itself. He died in 1504, and his successors gradually extended their possessions. In the reign of Akbar the chiefs of Bikaner were most loyal adherents of the Delhi empire, and in 1570 Akbar married a daughter of Kalyan Singh. Kalyan's son, Rai Singh, who succeeded him in 1571, was one of Akbar's most distinguished generals and the first raja of Bikaner; his daughter married Selim, afterwards the emperor Jahangir. Two other distinguished chiefs of the house were Karan Singh (1631-1669), who in the struggle of the sons

of Shah Jahan for the throne threw in his lot with Aurangzeb, and his eldest son, Anup Singh (1669-1698), who fought with distinction in the Deccan, was conspicuous in the capture of Golconda, and earned the title of maharaja. Wars of Bikaner with Jodhpur raged intermittently through the 18th century. On May 9, 1818 a treaty was concluded, and order was restored in the country by British troops. Ratan Singh, who succeeded his father in 1828, applied in vain in 1830 to the British government for aid against his *thakurs*; but during the next five years dacoity became so rife on the borders that the government raised a special force to deal with it (the Shakhawati brigade), and of this for seven years Bikaner contributed part of the cost. In 1842 Ratan Singh supplied camels for the Afghan expedition; in 1844 he reduced the dues on goods passing through his country, and he gave assistance in both Sikh campaigns. His son, Sardar Singh (1851-1872), was rewarded for help given during the Mutiny by an increase of territory. Sardar Singh had no son, and on his death in 1872 his widow and principal ministers selected Dungar Singh as his successor, with British approval. The rebellion of the *thakurs* in 1883, owing to an attempt to increase the dues payable in lieu of military service, led to the permanent location at Bikaner of a British political agent. Dungar Singh died in 1887 without a son; but he had adopted his brother, Ganga Singh (b. 1880), who succeeded as 21st chief of Bikaner with the approval of the government, and under whose enlightened rule the State has made striking progress.

BILASPUR, a town and district of British India in the Chhattisgarh division of the Central Provinces, situated on the right bank of the river Arpa. From a small village said to have been founded by a fisherwoman named "Bilasa," it became a Mahratta post and, after the lapse of the Nagpur State to the British, it was made the headquarters of the district in 1862. Its population was then under 5,000. When the Bengal-Nagpur railway was constructed in 1889 it became an important junction on the direct route between Bombay and Calcutta, a branch line connecting it through the Pendra Ghat and the Rewa State with the East Indian Railway at Katni. Its trade and importance have continued to increase and its population (1921) is 24,295. The American Mission has important educational institutions here, and there are the Government high school and its subsidiaries. There are also railway schools.

The District of Bilaspur, as now constituted, has an area of 7,618 square miles. It forms the upper half of the basin of the river Mahanadi. It is almost enclosed on the north, west and east by ranges of hills, while its southern boundary is well cultivated and closely dotted with villages embedded in mango groves. This area constituted the northern portion of the great Chhattisgarh plain (Chhattisgarh division). The Mahanadi is the principal river of the district, and governs the whole drainage and river system of the surrounding country. Flowing north from Raipur it crosses the Bilaspur boundary near Seorinarain, then turning south and east, after a course of 25 m., enters the Sambalpur district on its way to Bengal. The most important affluents of the Mahanadi are the Seonath and Hasdeo. The district is poorly protected from drought and suffers intensely in famines. In 1897 there was a heavy death-rate, and relief in 1899-1900 was carried out on a most lavish scale; there has been good recovery since.

Upon the formation of the Drug district, transfers of territory were made; the population of the areas now included in the district is (1921) 1,231,765. Formerly migration was very limited, but since the famines there has been much emigration to the Assam tea districts and there is an annual movement of surplus labour to Khargpur and Calcutta. The chief wealth of the district consists in its agricultural produce. Rice, the principal crop, is exported to Bombay, Berar and northern India. The tussur silk industry is of some importance. *Sal*, and other timber, is exported, and *Lac* is sent in quantities to Calcutta and Mirzapur. There is coal in the Korba Zamindari. Among local industries hand-weaving is important, and there is a match factory at Kotah.

The district includes several large Zamindari estates held on a special privileged tenure. Many of these are in wild and hilly

country with forests of considerable value. The Pandaria Zamin-dari in the west is more level and fertile.

Bilaspur has not been so fortunate as its neighbours in regard to the construction of large government irrigation works, but the deficiencies are being made up. Two large works are under construction (1928) and other projects under preparation.

(R. H. C.)

BILBAO, formerly sometimes written Bilboa, the capital of the province of Biscay, in northern Spain. Pop. (1920), 112,819. Bilbao is one of the principal seaports of Spain, and the greatest of Basque towns. It is situated picturesquely among hills on both sides of the river Nervión and about 8m. from the mouth of the river in the Bay of Biscay. The old town on the right bank includes the 14th century *Siete Calles* (Seven Streets), and its extensions to the north, which date from the 16th century onwards. The *Siete Calles* is one of the most remarkable examples of a mediaeval site laid out entirely to plan, remarkable both for its regularity and for the care taken by careful levelling to secure drainage and ventilation; its paved streets were long closed to horsemen and to wheeled traffic, and their cleanliness was the wonder of all visitors. With its high houses and narrow streets, the old town is to-day the principal business and shopping centre. The prosperity which followed the World War has led to far-reaching proposals for its alteration, in particular for the improvement of through communications by cutting two broad streets from the Puente de San Antón in the south, leading respectively to the Puente de la Merced and to the Puente de Isabel Segunda, the most important bridge carrying traffic to the new town. The new town (*Ensanche*) stands a little lower down the river on the left bank; it is built on modern and spacious lines, in rectangular blocks with main arteries of traffic radiating from central plazas. The plan for the new town was approved in 1876, and was conceived on a scale adequate to the subsequent needs of the town. At Olaveaga, about a mile off, is the Jesuit university, attended by 850 students. During the second half of the 19th century the population of Bilbao increased nearly fivefold, principally because of the development of the mining and metallurgical industries. The mining industry, producing chiefly iron ore, has declined in the present decade in sympathy with the depressed state of the British foundries which consume three-fourths of the ore produced, and in face of increased cost of production and of the growing competition from North Africa; the high-class ores are also becoming worked out. More satisfactory is the condition of the metallurgical industry, which has applied to modernization of plant a large portion of the enormous profits made during the World War. The exports are chiefly iron; the imports coal; large quantities of wine from Navarre and the Ebro valley are also sent abroad, and the importation of timber of all kinds from Scandinavia and Finland, and coastwise from Asturias, is of great importance. In the coasting trade the exports are mostly pig-iron, codfish and some products of local industries and agriculture. The port of Bilbao includes an outer harbour (with free port), protected by a breakwater and counter-mole constructed outside the bar of the river Nervión, between Santurce and the opposite headland at Algorta; the depth at low water alongside the quay of the free port is 33ft. At Bilbao itself there are quays, 6,560ft. in length, chiefly on the left bank; the depth alongside at low water varies from 13 to 15ft. Five dry docks are now available, varying in length from 325ft. to 614ft. and in depth from 21ft. to 25ft. In 1925, 1,304 ships engaged in foreign trade, of a total registered tonnage of 1,905,766, entered the port; of these 477 were Spanish and 278 British, the respective tonnages being 625,755 and 319,535. Both the shipping and ship-building industry of the port are beginning to revive, after a period of decline, under the influence of the government bounties accorded by Decree-law of 1925. Besides the mining and metallurgical industries, Bilbao has breweries, tanneries, flour mills, glass works, brandy distilleries, and paper, soap, cotton and mosaic factories.

Bilbao was founded by Don Diego López de Haro about 1300, and was given special privileges which enabled it soon to outstrip Portugalete, the port at the river mouth. Its importance was greatly increased by the establishment in 1511 of a Consulado

modelled on that of Burgos. The code of commercial regulations, drawn up first in 1459 by the merchant guild and revised from time to time by the Consulado, became in its final form—the *Ordenanzas de Bilbao* of 1737—the basis of the mercantile law of Spain and of many of the South American republics. This code had the advantage over its rival the *Libro del Consulado del Mar* of Barcelona—that it embraced both land and sea trade. Bilbao suffered notable sieges by the Carlists in 1835–36 and 1874.

See O. Jürgens, *Spanische Städte* (Hamburg, 1921 bibl.).

BILBERRY, BLAEBERRY or WHORTLEBERRY, known botanically as *Vaccinium Myrtillus* (family Ericaceae), a low-growing shrub, found in woods, copses and on heaths, chiefly in hilly districts. The stiff stems, from 6in. to 2ft. long, bear small ovate leaves with a serrate margin, and small, globose, rosy flowers tinged with green. The berries are dark blue, with a waxy bloom, and about one-third of an inch in diameter; they are used for tarts, preserves, etc. The plant is widely distributed throughout the north temperate and extends into the arctic zone. Cowberry or whimberry is an allied species, *V. Vitis-Idaea*, growing in similar situations, but not found in south-eastern England, distinguished by its evergreen leaves and red acid edible berry. The plant, native also to northern continental Europe and Asia, is widely distributed in North America, ranging from Massachusetts and Maine to Labrador, especially in the mountains, and north-westward to Alaska. In the eastern United States it is commonly called mountain cranberry. (See BLUEBERRY; CRANBERRY; VACCINIUM.)

BILBES, a town of lower Egypt, on the eastern arm of the Nile, 36m. N.N.E. of Cairo by rail. The Coptic name, Phelbēs, seems derived from Egyptian, but nothing is known of the place before mediaeval times. Considered the bulwark of the kingdom on that side, Bilbes was strongly fortified by the Mohammedans. In 1163–64 it was besieged for three months by the crusaders under Amalric, and in 1168 was captured and pillaged by another army of crusaders. Napoleon in 1798 ordered the restoration of the fortifications, but they have again fallen into decay.

BILBO (from the Spanish town Bilbao, formerly called in England "Bilboa," and famous, like Toledo, for its sword-blades), in the earliest English use, a sword, especially one of superior temper. In the plural form (as in Shakespeare's phrase "methought I lay worse than the mutines in the bilboes") it meant the irons into which offenders were put on board ship.

BILDERDIJK, WILLEM (1756–1831), Dutch poet, was the son of an Amsterdam physician. His parents were ardent partisans of the house of Orange, and Bilderdijk grew up with strong monarchical and Calvinistic convictions. After studying law at Leyden university, he practised as an advocate at the Hague. He refused in 1795 to take the oath to the new administration, and was consequently obliged to leave Holland. He went to Hamburg, and then to London, where his great learning procured him consideration. There he had as a pupil Katherina Wilhelmina Schweickhardt (1776–1830), the daughter of a Dutch painter and herself a poet. He married this lady in 1802. In 1806 he returned to Holland. He was kindly received by Louis Napoleon, who made him his librarian, and a member and eventually president (1809–11) of the Royal Institute.

A picture of the Bilderdijk household is given in the letters (vol. v., 1850) of Robert Southey, who stayed some time with Bilderdijk in 1825. Madam Bilderdijk had translated *Roderick* into Dutch (1823–24). For his work as a poet see DUTCH LITERATURE. His many-sided activity showed itself also in historical criticism—*Geschiedenis des Vaderlands* (1832–51), a conservative commentary on Wagenaar's *Vaderlandsche Historie*; in translations from the Greek and Latin classics, in philology, and in drama. His most important poetical works are the didactic poem, *De Ziekte der geleerden* ("The Disease of the Learned"), 1807; a descriptive poem in the manner of Delille in *Het Buitenleven* (1803); and his fragmentary epic, *De Ondergang der eerste wereld* (1820).

His poetical works were collected by I. da Costa (Haarlem, 1856–50) with a biography of the poet. See also "Mijne Levensbeschrijving" in *Mengelingen en Fragmenten* . . . (1834); his *Brieven* (ed. 1836–37)

by I. da Costa and W. Messchert; Dr. R. A. Kollewijn, *Bilderdijs, Zijn Leven en werken* . . . (1891).

BILEJIK, chief town of the Ertogrul vilayet in Asia Minor, altitude 1,900ft., situated on a hill 2½m. from its station on the Ismid-Angora railway. Pop. (1927), 21,427. It is an important centre of the silk industry, and has several silk-spinning factories.

BILFINGER or **BÜLFINGER, GEORG BERNHARD** (1693–1750), German philosopher, mathematician and statesman, was born on Jan. 23, 1693, at Kanstatt, Württemberg. He studied philosophy under Wolff, became professor of philosophy (1721) and then of mathematics (1724) at Halle. His *Dilucidationes philosophicae de deo, anima humana, mundo* (Tübingen, 1725) is a clear presentation of Wolff's philosophy. On Wolff's recommendation he was invited by Peter the Great to lecture at St. Petersburg, and he remained there from 1725 to 1731. In the latter year he returned to Germany, became professor of theology at Tübingen, and a member of Duke Charles Alexander's council. On the duke's death he became a member of the Regency Council, and helped to reorganize education and agriculture in the State. He died at Stuttgart on Feb. 18, 1750.

Beside the *Dilucidationes*, he wrote:—*De Harmonia animi et corporis humani commentatio* (Frankfort and Leipzig, 1725); *De origine et permissione mali* (1724), an account of the Leibnizian theodicy.

See Tafinger, *Leichenrede* (Stuttgart, 1750); Abel, in Moser's *Patriot, Archiv*, ix. p. 369 (1788); Spittler, *Verm. Schriften*, xii. p. 421; R. Wahl, "Bilfinger's Monadologie" *Zeitschrift für Philos.* (1884); E. Zeller, *Geschichte d. deutsch. Philos. seit Leibnitz*.

BILGE, the widest part or "belly" of a cask; the broad horizontal part of a ship's bottom above the keel; also the lowest interior part of the hull; hence, "bilge-water," the foul water which collects in the bilge. "Bilge-keels" are pieces of timber fastened to the bottom of a ship to reduce rolling. The word is a corruption of bulge, from Fr. *bouge*, Lat. *bulga*, a bag, probably deriving from an original Celtic word.

BILGRAMI, SAYYID HUSAIN (1843–1926), Indian statesman, a member of a well-known Mohammedan family, was educated at the Presidency college, Calcutta, and became professor of Arabic at Lucknow. In 1884 he was attached to the service of the Nizam of Berar, where he was director of education for 20 years. He helped to build up the Mohammedan Oriental college at Aligarh, which is now a university; in other ways he promoted Mohammedan interests in India, and from 1907 to 1909 was a prominent member of the India Council in London. He died on June 9, 1926.

BILHARZIASIS or **SCHISTOSOMIASIS**, a disease characterized by haematuria or by discharge of blood and mucus by the rectum caused by the fluke parasite schistosoma and endemic throughout Africa, South America and the West Indies, China, Japan, the Philippines, Formosa, Burma, India and Western Australia. One European country only, south Portugal, is known to be infected by schistosomiasis (1925).

Causation.—Schistosomiasis is caused by certain metazoal parasites of the family Schistosomidae Looss-1899 (type genus *Schistosoma* Weinland 1858) belonging to the trematode class of the phylum Platy-helminthes. In the schistosomidae the sexes are separate, and the alimentary canal is united posteriorly into a single tube. In the known human species the egg is furnished with a characteristic spine (point) or knob. A ventral (gynaecological) canal for carrying the cylindrical female worm is formed by the infolding lateral margins of the leaf-shaped male.

There are three known human species; *Schist. haematobium*, the chief African species infects principally the bladder; *Schist. mansoni*, also found in Africa, the only species infecting America, affects the large intestine; *Schist. japonicum*, the Asiatic species, affects the large intestine and liver and spleen.

The adult worms inhabit the portal venous system, reach maturity in the liver and pass in the portal tributaries to the pelvic veins in the bladder and large intestine to lay their eggs, which reach the exterior world in the urine and faeces. In fresh water under favourable conditions the ovum hatches the ciliated embryo (miracidium).

If during its short active life it approaches an appropriate water-snail, it penetrates and bores its way to the pancreatico-hepatic gland and encysts. Bifid larvae (cercariae) develop within the daughter cysts and escape when the snail ruptures. The parasite again becomes free swimming Cercariae survive not longer than 36 hours. They are attracted by and penetrate human skin and mucous membranes immersed in the water. They discard the tail and are carried by the blood and lymph to the lungs and from thence to the liver where they mature. Definite symptoms of schistosomiasis may be expected two months or later from the time of contact with infected water.

Treatment.—In 1917 Christopherson in Khartum found that antimony tartrate administered intravenously was an infallible parasiticide for both species of Egyptian schistosomiasis, and worked out the method of treatment by antimony which has since been adopted. Later it was found that antimony tartrate was an equally trustworthy parasiticide for Asiatic schistosomiasis. Recovery is the rule provided reinfection is obviated. Death takes place from toxæmia due to a heavy infection, from intercurrent disease, from impairment of liver function, from complications caused by the damaged organs and secondarily from stone in the bladder or cancer.

Preventive Measures.—Theoretically schistosomiasis can be stamped out of a locality by (1) curing all the cases, (2) killing

AFTER LOOSER AND FROM "AMERICAN JOURNAL OF HYGIENE" THE SCHISTOSOMA PARASITE, RESPONSIBLE FOR BILHARZIASIS, A DISEASE TO WHICH MAN IS SUBJECT IN AFRICA AND OTHER COUNTRIES Above are shown the main water snails that serve as intermediate hosts of the parasites; below, the stages from the ovum to the adult worm

the intermediary hosts (water snails), (3) preventing the mollusc infecting man, and man the mollusc. This is effected by the intravenous injection of antimony tartrate (Pot. or Sod) daily for five days, afterwards three times a week until the necessary total (adult) amount (25–30 grains) is reached. Antimony is contraindicated in cardiac and renal disease and when the liver is extensively disorganized. Emetin is given when antimony tartrate is not tolerated. Extermination of the snails is accomplished by

chemicals which kill the mollusc but are beneficial to or do not interfere with the fertility of the soil, chiefly calcium and ammonium compounds. In Egypt where irrigation is under government control, Leiper recommended the periodical drying up in rotation of irrigation canals for 15 days. The natural enemies of the snail (ducks) are to be encouraged. Water contaminated by bilharzia, if kept for two days, is innocuous for domestic purposes.

BILIN: see BILINA.

BILINA, a small town of Bohemia, Czechoslovakia, situated on the Biele within the Germanized belt of the country. Like many towns in this region it is famous for its mineral springs, the Biliner Sauerbrunnen, which have a temperature of 45-6° F and contain bicarbonate of soda. The water is bottled and exported in large quantities and is also evaporated for its salt. South of the town rise the volcanic heights of the Mittelgebirge, a region of wide panoramas notably from the Rudenstein (2,460ft.), while northward it has easy access to the lignites of the Most-Teplice basin.

BILINGUALISM. In many parts of the world people use one language inside the family circle and speak another, sometimes of a different type, freely and naturally, outside the family circle. Or two languages may exist side by side in the same country and be used freely by the inhabitants both at home and outside the home. One may develop into a lingua franca (*q.v.*) and the other remain a local dialect. The conflict between localization and unification goes on everywhere and affects language as a social instrument and institution. Inside a society, if education is the privilege of the few, there will be found such differences between the speech of the educated and the uneducated classes as to produce a kind of bilingualism. A man may write like an angel and talk like poor Poll. The purists in Athens and Bengal go to classical models while the speech of the people—living—subject to the life of the people—develops independently. Then there are cases of politically advanced communities where two distinct languages are spoken in the same area, are taught in the schools and are recognized for official purposes. There are cases, too, unhappily not infrequent in history where a ruling people has thrust its language on a conquered country. But so closely is language bound up with national and religious life that the former language will be kept alive by patriotism.

The study of bilingualism in the strict sense involves, therefore, scrutiny of its distribution, of the conditions in which it occurs, of the nature and extent of the effects which it produces on the phonetic and structural systems of both languages, the familial and the external. Regard must be had to the conditions in which the second or external language is acquired and used, to the linguistic affinities of the two languages and to the psychological, economic and political conditions of contact. (See **CULTURE CONTACT**.)

Distribution.—The languages of the world are divided into families and groups. (See **LANGUAGES, DISTRIBUTION OF**) The identification of the boundaries of a language is not always an easy matter. Since natural bilingualism occurs when two languages come into contact, the occasion for bilingualism is almost world wide. In Europe for instance, Magyar, a Finno-Ugrian language, is surrounded by languages which belong to the Slavonic, Romance and Teutonic groups.

Finnish speech is in touch with Russian and Swedish, and Russian in turn farther East is in contact with Mongol and Chinese. In India, Brahui, a Dravidian language is ringed round with Iranian tongues, and in the south the Dravidian languages encounter Indo-Aryan languages along a great frontier. There are Dravidian areas surrounded or in touch with Austric (Munda) speech. Assam and Burma, too, have linguistic frontiers. Austric speech meets Papuan in New Guinea. In American conditions there are people such as the Mayas who are even trilingual for they speak Maya in their homes, learn Spanish in the mission schools and use English in trade.

Social Conditions.—The family is the most important group in all societies as the first instrument of cultural transmission. The conditions in which the first or familial language is learnt are not repeated exactly when a second language has to be learnt.

The form of the family, the modes of marriage observed, polygamy, matrilineal and patrilineal marriage, induce variations in linguistics as in other social matters.

Marriage with strangers may be allowed, encouraged or, more usually, forbidden and disliked. Some societies are exclusive, jealous of strangers, resistant to new ideas. Others, those in which bilingualism flourishes, are willing, even eager to seek intercourse with others. Here and there occur special cases where only historical knowledge can explain a difficult linguistic phenomenon as among the Caribs who killed off the Arawak men and took the women as captives. The women spoke Arawak, their own language, and taught it to their daughters, but the boys were taken by their fathers often at an early age for long voyages and expeditions and so learnt Carib. In Burma mixed marriages of Burmese women with Chinese men are known and the girls are brought up as Burmese while the boys follow the father.

Phonetics.—Every language has a distinctive phonetic system and a distinctive pattern of structure. Neither is absolutely rigid, incapable of modification. Changes occur, from internal causes and by reasons of external contacts. These changes are however directed by the pre-existing system and structure. But while a single sound change such as may be introduced in association with bilingualism may upset the old phonetic pattern by bringing in disharmony, there can be seen in all languages a general drift in a definite direction, compensated and controlled by a readjusting tendency and a conservative tendency.

Structure.—Something like an ideal linguistic entity dominates the speech habits of the members of each group and modifications and variations of all linguistic phenomena have to be correlated with this ideal entity.

Slight phonetic readjustment or unsettlement may in the course of millennia bring about the most profound structural changes. Thus a growing tendency to throw the stress automatically on the first syllable of a word may eventually change the fundamental type of a language, reducing its final syllables to zero. One of the most potent causes of unsettling a language is any widespread bilingualism, whether open or, as is often the case, secret and unsuspected.

Certain languages have structural features due to the suggestive influence of neighbouring languages.

How great the influence of one language on another may be, even when the two belong to different language families, is shown by the present condition of Finnish, Estonian and Magyar and Finno-Ugrian languages. It is said that a reader familiar with other European speech will find nothing fundamentally original in the syntax of the sentences of a journal in these languages, apart from a few idiomatic expressions.

Vocabulary.—Borrowed words are made to conform to the phonetic pattern of the borrowing language and are often sorely changed in the process. Then a psychological principle seems to be at work by which certain types of words are selected or are preferred for assimilation as conforming to the inner type of the borrowing language. Some languages find it easier to create new words out of their own resources.

Words have an association with other words in their pristine vocabulary and lose this value at least in part when adopted into a new home where they acquire association with another and generally very different set of ideas and thus gain a new meaning.

BILL. There are three words in English with distinct meanings and derivations. (1) A written, originally sealed, document. The word is derived from the Early English *bille*, Anglo-Latin *billa*, from Latin *bullā*, in the mediaeval sense of "seal." It is a doublet, therefore, of "bull." (2) A common Teutonic word

for a long-handled cutting weapon of which the name and shape is preserved in the bills or bill-hooks used for pruning hedges and lopping the branches of trees. For an account of the weapon see (2) in the next column. (3) The beak of a bird.

(1) In the sense of a document the word is used in various connections in law and commerce.

In the English parliament, and similar legislative bodies, a bill is the draft of a proposed statute (*q.v.*) submitted to either house, which when finally passed becomes an act. The modern system of legislating by means of bill and statute appears to have been introduced in the reign of Henry VI., superseding the older mode of proceeding by petitions from the Commons, assented to by the king, and afterwards enrolled by the judges. (For procedure see PARLIAMENT.)

A *Bill in Chancery*, in former days, in English law, was a written statement of the plaintiff's case whereby he complained of the wrong upon which the suit was based and prayed for relief. By the Judicature Acts 1873 and 1875 its place was taken by a writ and statement of claim (see PRACTICE and PROCEDURE).

A *Bill of Indictment* is a presentment against a prisoner, charging him with an offence, and presented at quarter sessions or assizes to the grand jury (see INDICTMENT).

A *Bill of Costs* is an account setting forth the charges and disbursements incurred by a solicitor in the conduct of his client's business (see COSTS).

A *Bill of Exceptions* was formerly a statement in writing of objections to the ruling of a judge, who, at a civil trial, had mistaken the law, either in directing the jury, or in refusing or admitting evidence or otherwise. It was abolished by the Judicature Act 1875, and a "motion for a new trial" substituted.

A *Bill of Health* is a document given to the master of a ship by the consul or other proper authority of the port from which he clears, describing the sanitary state of the place. A bill of health may be either "clean," "suspected" or "touched," or "foul." A "clean" bill imports that at the time the ship sails no disease of an infectious or contagious kind is known to exist; a "suspected" or "touched" bill, that no such disease has as yet appeared, but that there is reason to fear it; a "foul" bill, that such a disease actually exists at the time of the ship's departure. Bills of health are necessary where the destination of the ship is a country whose laws require the production of such a bill before the ship is allowed into port, and where, in default of such production, the ship is subjected to quarantine.

A *Bill of Mortality* in England was a weekly return issued under the supervision of the company of parish clerks showing the number of deaths in a parish. During the Tudor period England suffered much from plague, and various precautionary measures became necessary. Quarantine or isolation was the most important, but to carry it out successfully it was necessary to have early warning of the existence of plague in each parish or house. For this purpose searchers—usually women—were appointed, who reported to the clerk the cause of each death in the parish. He, in turn, sent a report to the parish clerks' hall, whence was issued weekly a return of all the deaths from plague and other causes in the various parishes, as well as a list of those parishes which were free from plague. Bills of mortality are usually said to date from 1538, when parish registers were established by Cromwell (Lord Essex), but there is extant a bill which dates from Aug. 1535, and one which is possibly even earlier than this. It is certain that they first began to be compiled in a recognized manner in Dec. 1603, and they were continued regularly from that date down to 1842, when under the Births and Deaths Registration Act 1836 they were superseded by the registrar-general's returns. It was not till 1728, when the *ages* of the dead were first introduced, that bills of mortality acquired any considerable statistical value. It was on the data thus furnished that the science of life insurance was founded.

A *Bill of Particulars* was, in law, a supplementary statement in writing, informing each party to a suit of the precise nature of the case he had to meet.

A *Bill of Peace* is, in equity, a suit brought by a person to establish and perpetuate a right which he claims, and which from

its nature may be controverted by different persons at different times and by different actions; or where several attempts have already been unsuccessfully made to overthrow the same right, and justice requires that the party should be quieted in the right if it is already sufficiently established. Bills of this nature were usually filed where there was one general right to be established against a great number of persons, or where one person claimed or defended a right against many, or where many claimed or defended a right against one. Thus, a bill might be filed by a parson for tithes against his parishioners; by parishioners against a parson to establish a *modus*; by a lord against tenants for an encroachment under colour of a common right; or by tenants against a lord for disturbance of a common right. Bills were also filed in cases where the plaintiff had, after repeated and satisfactory trials, established his right at law, and yet was in danger of further litigation and obstruction to his right from new attempts to controvert it. Actions in the nature of bills of peace are still maintainable.

A *Bill of Sight* is a document furnished to a collector of customs or other proper officer by an importer of goods in England, who, being unable for want of full information to make a perfect entry of goods consigned to him, describes the same to the best of his knowledge and information. The goods may then be provisionally landed, but perfect entry must be made within three days by indorsing on the bill of sight the necessary particulars. In default of perfect entry within three days the goods are taken to the king's warehouse, and if perfect entry is not made within one month and all duties and charges paid, they are sold for payment thereof. See the Customs Consolidation Act 1876.

A *Bill of Store* is a licence granted by the custom-house to re-import British goods into the United Kingdom. All British goods re-imported into the United Kingdom are entered as foreign, unless re-imported within ten years after their exportation and unless the property in the goods continues and remains in the person by whom they were exported. But in such case they may be entered as British goods, by bill of store, with certain exceptions.

A *Bill of Victualling* or *Victualling Bill*, in its original meaning, is a list of all stores for shipment, but now an order from an export officer of the customs for the shipment from a bonded warehouse or for drawback of such stores as may be required and allowed with reference to the number of the crew and passengers on board a ship proceeding on an overseas voyage. It is made out

TYPES OF OLD ENGLISH BILL

On the left is a bill of the time of Edward IV.; the centre bill is Elizabethan, and that on the right, a Watchman's bill of the 17th century.

A victualling bill serves as a certificate of clearance when there is nothing but stores on board the ship.

See also ATTAINDER, INDEMNITY, LETTER OF CREDIT, BILL OF EXCHANGE, BILL OF RIGHTS and BILL OF SALE; for a *bill of lading* see AFFREIGHTMENT.

(2) Meaning a weapon, a common Teutonic name for a long-handled weapon with a cutting edge (O.E. *Bil*, *billes*, sword or falchion, O. Sax. *bill*, M.H.G. *Bil*, Mod. Ger. *Bille*, a pickaxe; no connection with Ger. *Beil*, an axe), of which the name and shape is preserved in the hedging-bills used for pruning hedges and lopping the branches of trees.

The primitive forms of a bill suggest short scythe-blades or

hedgers' bill-hooks mounted on tall staves. In such shape it is found in the hands of the English before the Conquest. English mediaeval documents make much confusion between the bill and the halbert and other forms of staved weapons with cutting heads. Before the 15th century the bill had been reinforced with a pike head above the curved blade and another jutting at a right angle from the blade's back. In this form it became a popular English weapon, the "brown bill" of many ballads.

Billmen are not found in the king's host at Crecy and Calais, the bowmen carrying mallets or short swords, and Henry VII's contracts for troops do not name the bill, which may be regarded rather as the private man's weapon. But when, in the middle of the 15th century, Walter Strickland, a Westmorland squire, contracts to raise armed men, it is noticeable that more than half his horsemen carry the bill as their chief arm, while 71 bowmen are to march on foot with 76 billmen. In the 16th century the bill, with the halbert, fell out of use among regular troops, the pike taking their place on account of the longer staff, which made it a better defence against cavalry. It remained during the 17th century as a watchman or constable's weapon, although rudely-fashioned bills were seen in the Sedgemoor fight. (O. B.)

BILLAUD-VARENNE, JACQUES NICOLAS (1756-1819), French revolutionary, was the son of an *avocat* at the parlement of Paris. In 1785 he left the Oratorian College where he was prefect of studies, married and bought a position as *avocat* in the parlement. Early in 1789 he published at Amsterdam a three-volume work on the *Despotisme des ministres de la France*, and he adopted with enthusiasm the principles of the Revolution.

At the Jacobin club he became from 1790 one of the most violent of the anti-royalist orators. After the flight of Louis XVI. to Varennes, he published a pamphlet, *L'Acéphocratie*, in which he demanded the establishment of a federal republic. In the night of Aug. 10, 1792, he was elected one of the "deputy-commissioners" of the sections who shortly afterwards became the general council of the commune. Elected a deputy of Paris to the National Convention, he at once spoke in favour of the immediate abolition of the monarchy, and the next day demanded that all acts be dated from the year 1 of the republic. At the trial of Louis XVI. he added new charges to the accusation, proposed to refuse counsel to the king, and voted for death "within 24 hours." On June 2, 1793, he proposed a decree of accusation against the Girondists; on June 9, at the Jacobin club, he outlined a programme which the Convention was destined gradually to realize: the expulsion of all foreigners not naturalized, the establishment of an impost on the rich, the deprivation of the rights of citizenship of all "anti-social" men, the creation of a revolutionary army, the licensing of all officers *ci-devant* nobles, the death penalty for unsuccessful generals. Sent in August as "representative on mission" to the departments of the Nord and of Pas-de-Calais, he showed himself inexorable to all suspects. On his return he was added to the Committee of Public Safety and published a book, *Les Éléments du républicanisme*, in which he demanded a division of property, if not equally, at least proportionally among the citizens. But he became uneasy for his own safety and turned against Robespierre, whom he attacked on the 8th Thermidor as a "moderate" and a Dantonist. Surprised and menaced by the Thermidorian reaction, he denounced its partisans to the Jacobin club. He was then attacked himself in the Convention for his cruelty, and a commission was appointed to examine his conduct and that of some other members of the former Committee of Public Safety. He was arrested, and as a result of the insurrection of the 12th Germinal of the year 3 (April 1, 1795), the Convention decreed his immediate deportation to French Guiana. After the 18th Brumaire he refused the pardon offered by the First Consul. In 1816 he left Guiana and took refuge in Port-au-Prince (Haiti), where he died of dysentery.

In 1821 were published the *Mémoires de Billaud-Varenne écrits à Port-au-Prince* (Paris), but they are probably forgeries. An interesting autobiographical sketch of his youth, "Tableau du premier âge," composed in 1786, was published in 1888 in the review, *La Révolution française*. (See also FRANCE: History.)

BILLBOARDS, the general term which in the United States and Canada designates advertising by means of painted or proc-

essed bulletins and posters. In Great Britain the term "hoardings" is used rather than billboards. This name was derived from the hoardings upon which posters were so frequently placed. From the indiscriminate pasting up of advertising sheets which were left unattended and soon became ragged and unsightly, bill-posting has been developed into an extensive and highly organized business. Painted bulletins usually consist of steel or wooden panels, framed and held in position by specially constructed forms. The usual practice is to repaint these every four months and contracts with the larger posting companies are uniform as to this clause. They are not of uniform size but are constructed to fit the space available. Rates are governed by the size and the number of people likely to see the notice.

Posters are paper sheets printed or lithographed. In the United States and Canada they are uniform in size. There are two different units: the more popular one is the "24-sheet" poster which is about 9 by 25 ft. including the frame around the panel; the smaller unit, called the "3-sheet" poster is approximately 3 by 7 feet. Although there are many concerns that are engaged in bill-posting they are so organized that practically the whole of North America can be covered through the association of bill-posters so that the advertiser will have but one contract to make and one bill to pay.

The charge for bill-posting is also highly standardized. Each city is divided up into a number of equally prominent showings and these are designated in the business as "standard set showings." The "regulars" are charged from \$7 to \$7.50 a month, the advertiser supplying the lithographed sheets. "Specials" are stands located where traffic is heavy and these are often illuminated at night. The rental for the specials is from \$20 to \$30 a month. In New York city 200 regulars and 124 specials are required for an "intensive showing" in Manhattan and the Bronx. It would be possible for 14 advertisers each to employ an intensive showing at the same time in this district. They would reach approximately the same number of people and would be charged the same price. If it were desired to make a smaller investment, a "representative" or "half" showing could be taken, which would be of course 100 regulars and 62 specials. A few boards are sold as miscellaneous, primarily to local advertisers.

Few branches of advertising have made such improvement in their methods of doing business in the last few years as bill-posters. Formerly, the obtrusive sheets were pasted on buildings, fences, hoardings and even on freight cars, water tanks, etc. The public rebelled against this unsightly display which caused the bill-posters to unite and reorganize the whole business. Now posters are not placed on residence streets; they are not allowed to become ragged or soiled. The bill-posters agree to keep the poster in presentable condition for the term of the contract and will replace the paper without cost if it becomes unattractive for any reason. Copy is carefully censored and no objectionable pictures or messages are permitted. With the reorganization of the business, the volume has been greatly increased. The two leading bill-posting companies of the United States and Canada now do an annual business in excess of \$50,000,000.

Bill-posting is a form of advertising popular with advertisers who wish to appeal to the masses. Particularly is this true if the product can be attractively presented by a picture and a few words. With the more rapid forms of transportation, the copy has been condensed until 10 to 20 words is now regarded as the maximum length of a profitable message. One American advertiser spent \$3,000,000 on billboards in 1927. This provided a full showing for the whole country. (See POSTERS.) (H. E. A.)

BILL-BROKER, a broker who deals in bills of exchange. Bill-brokers specialize in bill-discounting, and their operations are very varied in character. They may deal for themselves as principals or for others as agents. When they sell bills of exchange on commission, they are purely brokers; this function has become almost obsolete. When they buy bills of exchange to sell again at a profit they become, in effect, bill-merchants. When, enlarging their functions, they deal in bills on the grand scale, employing much capital derived from depositors, they become what are called "discount houses." (See BILL OF EXCHANGE; MONEY MARKET; DISCOUNT AND DISCOUNT HOUSES.)

BILLET. (1) A small paper or "note," commonly used in the 18th and early 19th centuries as a "billet of invitation" (Fr. *billet*, diminutive of *bille*, a writing). A particular use of the word is to denote an order issued to a soldier entitling him to quarters with a certain person (see **BILLETING**). From meaning the official order, the word *billet* came to be used of the quarters thus obtained, giving rise to such expressions as "a good billet." Another sense of the word is that of a voting-paper occurring in the 17th century with reference to the Act of Billets passed by the Scottish parliament in 1662.

(2) A piece of wood roughly cylindrical, cut for use as fuel (Fr. *billette* or *billot*, diminutive of *bille*, the trunk of a tree). In mediaeval England it was used of the club or bludgeon which was the weapon proper to the serf. The name has been transferred to various objects of a similar shape, e.g. ingots of gold, or bars of iron or steel; and in heraldry (*q.v.*) to a bearing of rectangular shape. The term is applied in architecture to a form of ornamental moulding used in Norman and sometimes in Early English work. It resembles small billets of wood arranged at regular intervals in a sunk moulding. In early French architecture it sometimes forms the decoration of a string course.

BILLETING, a method of providing temporary accommodation for military forces by lodging them in parties on the inhabitants of a district (See **CANTONMENT: MILITARY TERMS**).

BILLET-MOULDING, in architecture, a type of moulding much used in the Norman, Anglo-Norman and early Gothic styles; it consists of a series of small sections of *torus* (*q.v.*) or bead-moulding (*q.v.*) with spaces between them. Frequently, two or three rows of billet-moulding are combined, the projecting portions of one row directly above or below the flat portions of the next; occasionally the *torus* or bead will be bent at right angles to connect two such rows. The French term, which is much used in architectural books in English, is *bâton rompu*.

BILLIARDS, an indoor game of skill, played on a rectangular table, and consisting in the driving of small balls with a stick called a cue either against one another or into pockets according to the methods described below. The revised rules of all the recognized games (as authorized by the Billiards Association and Control Council) can be obtained from all billiard table manufacturers or the offices of billiard journals. The name probably originated in the Fr. *bille* (connected with Eng. "billet") signifying a stick. Of the origin of the game comparatively little is known. In an American text-book, *Modern Billiards*, it is stated that Cathaire More (Conn Cetchathach), king of Ireland in the 2nd century, left behind him "fifty-five billiard balls, of brass, with the pools and cues of the same materials." The same book refers to the travels of Anacharsis through Greece, 400 B.C., during which he saw a game analogous to billiards. French writers differ as to whether their country can claim its origin, though the name suggests this. While it is generally asserted that Henrique Devigne, an artist, who lived in the reign of Charles IX., gave form and rule to the pastime, the *Dictionnaire universel* and the *Académie des jeux* ascribe its invention to the English. Bouillet in the first work says: "Billiards appear to be derived from the game of bowls. It was anciently known in England, where, perhaps, it was invented. It was brought into France by Louis XIV., whose physician recommended this exercise." In the other work mentioned we read: "It would seem that the game was invented in England." It was certainly known and played in France in the time of Louis XI. (1423-83). Strutt (*Sports and Pastimes of the People of England*) considers it probable that it was the ancient game of Paillemaille (Pall Mall) on a table instead of on the ground or floor—an improvement, he says, "which answered two good purposes: it precluded the necessity of the player to kneel or stoop exceedingly when he struck the bowl, and accommodated the game to the limits of a chamber." Whatever its origin, and whatever the manner in which it was originally played, it is certain that it was known in the time of Shakespeare, who makes Cleopatra, in the absence of Anthony, invite her attendant to join in the pastime—

"Let us to billiards: come, Charmian."

—*Ant. and Cleo. Act. ii. sc. 5.*

In Cotton's *Compleat Gamester*, published in 1674, we are told that this "most gentle, cleanly and ingenious game" was first played in Italy, though in another page he mentions Spain as its birthplace. At that date billiards must have been well enough known, for we are told that "for the excellency of the recreation, it is much approved of and played by most nations of Europe, especially in England, there being few towns of note therein which hath not a public billiard table, neither are they wanting in many noble and private families in the country."

ENGLISH BILLIARDS

The English table consists of a framework of mahogany or other hard wood, with eight legs, strong enough to bear the weight of five slabs of slate, each 2½ ft. wide by 6 ft. 1½ in., and about 2 in. thick. These having been fitted together to form a level surface, and a green cloth of the finest texture having been tightly strained over it, the cushions are screwed on, and the pockets, for which provision has been made in the slates, are adjusted. As the inside edge of the cushion is not perpendicular to the bed of the table, but is bevelled away so that the top overhangs the base by about ¾ of an inch, the actual playing area of the table is 6 ft. wide but is 1½ in. short of 12 ft. long. The height of the table from the floor to the top of the cushion rail must be from 2 ft. 9½ in to 2 ft. 10½ inches.

The three spots are on the centre line of the table, and are usually marked by small circular pieces of black tissue paper or court plaster; sometimes they are specially marked for the occasion in chalk. The *baulk* line and the D are marked either with chalk, tailors' pipeclay, or an ordinary lead pencil; no other marks appear on the table. Smaller tables and dinner tables convertible into billiard tables provide plenty of practice and amusement, provided that the relation of the length to the breadth be observed. On these tables full-sized balls may be used, the pockets being made slightly smaller than in the full-size table.

In the early part of the 19th century the bed of the table was made of wood, occasionally of marble or stone; green baize was used to cover both the bed and the cushions, the latter made of layers of list. Then, as now, the cushions were glued to a wooden framework which is screwed on to the bed of the table. The old

FROM JUSSEURAND, "LES SPORTS ET JEUX D'EXERCICE DANS L'ANCIENNE FRANCE" PUBLISHED BY LIBRAIRIE PLOIN

LOUIS XIV. OF FRANCE ENGAGED IN PLAYING BILLIARDS, 1694

The game of billiards was popular in Europe during the middle ages. Louis XIV. is reputed to have introduced it into France. It was played with peculiar shaped cues and without pockets.

list cushions possessed so little resilience that about 1835 india-rubber was substituted, the value of the improvement being somewhat modified by the fact that in cold weather the rubber became hard and never recovered its elasticity. Vulcanite resisted the cold, but was not "fast" enough, i.e., did not permit the ball to rebound quickly; but eventually a substance was invented, practically proof against cold and sufficiently elastic for all purposes. Late in the 19th century pneumatic cushions were tried, tubes into which air could be pumped, but they did not become popular, though the so-called "vacuum" cushions give good re-

sults. The shape of the face of the cushion has gone through many modifications, owing to the difficulty experienced in the actual striking of the ball when resting against the cushion with only a small fraction of its surface offered to the cue; but low cushions are made which expose nearly half of the upper part of the ball.

From 1870-85 matches for the championship were played on "championship tables," the pockets measuring only 3 in. at the "fall." The tables in ordinary use have 3½ in. pockets, but in the "standard tables," introduced by the Billiard Association at the end of the 19th century, the pockets are slightly smaller, the Association providing templates which a table must pass before being recognized as a "standard."

The principal games are three in number—*billiards*, *pyramids* and *pool*, and from these spring a variety of others. The object of the player in each game, however, is either to drive one or other of the balls into one or other of the pockets, or to cause the striker's ball to come into successive contact with two other balls. The former stroke is known as a *hazard* (a term derived from the fact that the pockets used to be called hazards in old days), the latter as a *cannon*. When the ball is forced into a pocket the stroke is called a winning hazard; when the striker's ball falls into a pocket after contact with another ball, the stroke is a losing hazard; "red hazards" means that the red ball is the object ball, "white hazards" the white.

The *spot-stroke* is a series of winning hazards made by pocketing the red ball into one of the top pockets off the spot. The object is, first, to make sure of the hazard, and next, to leave the striking ball in such a position as to enable the player to repeat the stroke. It was known as long ago as 1825 when a run of 22 spots caused quite a sensation. John Roberts, sen., who succeeded Kentfield as champion in 1849, worked hard at the stroke, but never made, in public, a longer run than 104 in succession. But W. Cook, John Roberts, jun., and others, assisted by the improvements made in the implements of the game, soon outdid Roberts, sen., only to be themselves outdone by W. J. Peall and W. Mitchell. In 1888 W. J. Peall made 663 "spots" in succession, and in 1890 in a break of 3,304—the longest spot break—no less than 3,183 of the points were scored by spot strokes. C. Memmott made 423 winning hazards into one pocket by the aid of the "screw-back." The result was that the Association altered the rules in such manner as to make the stroke practically impossible.

Top-of-the-Table Play.—When the spot-stroke was dying, many leading players, headed by John Roberts, jun., assiduously cultivated another form of rapid scoring, known as "top-of-the-table play," the first principle of which is to collect the three balls at the top of the table near the spot. The balls are then manipulated by means of alternate red winning hazards and cannons.

The Push-Stroke.—Long series of cannons were also made along the edge of the cushion, mainly by means of the "push-stroke," and with great rapidity, but eventually the push-stroke too was barred as unfair.

Balls Jammed in Pockets.—If the two object-balls get jammed, either by accident or design, in the jaws of a corner pocket, an almost interminable series of cannons may be made by a skilful player. T. Taylor made 729 cannons in 1891, but the American champion, Frank C. Ives, in a match with John Roberts, jun., easily beat this in 1893, by making 1,267 cannons before he deliberately broke up the position. In Ives's case, however, the balls were just outside the jaws, which were skilfully used to keep the balls close together; but in this game, which was a compromise between English and American billiards, 2¼-in balls and 3¼-in pockets were used. Under the aegis of the Billiard Association a tacit understanding was arrived at that the position must be broken up, should it occur. A similar position came into discredit in 1907 in the case of the "cradle" or "anchor" cannon, where the balls were not actually jammed, but so close on each side of a pocket that a long series of cannons could be made without disturbing the position—a stroke, discovered by an amateur, introduced by Lovejoy in 1907, and carried to extremes by W. Cook and T. Reece. The former, a son of the old champion, was given a certificate by the Association for a break of 42,746, while the latter, in a game of half a million, made a break of 449,135.

Rules were then framed to make such affairs impossible. But in 1927, owing to a flaw in the wording of the rules, Reece discovered a method of evading them, known as the "pendulum" cannon, and fresh rules had to be drafted to overcome his ingenuity.

A *long jenny* is a losing hazard made into one of the top pockets, when the object ball is close to the cushion along which the striker's ball must travel. *Short jennies* are similar strokes into the middle pockets.

Massé and *Piqué* are difficult strokes made by striking downwards on the upper surface of the cue-ball, the cue being held nearly at right angles to the table.

When the cue-ball is so played that its centre is aimed at the extreme edge of the object-ball, the cue-ball's course is diverted at what is called the "*natural*" or "*half-ball*" angle. This half-ball angle is regarded as the standard angle for billiards, providing, as it does, a definite spot, the edge of the object-ball, at which to aim.

Development in Billiard Play.—The modern development of English billiards is due mainly to the skill of such leading players as John Roberts, sen., and his son of the same name. Indeed, their careers form the history of modern billiards from 1849 when the elder Roberts challenged Kentfield (who declined to play), to the end of the 19th century. No useful comparison can be made between the last-named men, and the change of cushions from list to india-rubber further complicates the question. Kentfield represented the best of the old style of play, and was a most skilful performer; but Roberts had a genius for the game, combined with great nerve and physical power. This capacity for endurance enabled him to practise single strokes till they became almost certainties, when weaker men would have failed from sheer fatigue; and that process applied to the acquisition of the spot-stroke was what placed him decisively in front of the players of his day until a younger generation taught by him came forward. It is curious to realize that John Roberts, sen., developed the game chiefly by means of spot-play, whereas his son continued the process by abandoning it. The public, however, liked quick scoring and long breaks, and therefore a substitute had to be devised. This was provided by the younger Roberts, whose fertility of resource and manual dexterity eventually placed him by a very long way at the head of his profession. In exhibition matches he barred the spot-stroke and gave his attention chiefly to top-of-the-table play.

The next development was borrowed from the French game, which consists entirely of cannon strokes. Both French and

STANDARD SIZE ENGLISH BILLIARD TABLE, WITH MEASUREMENTS SHOWN. The length and breadth of the English Billiard table are as shown: the height may vary between 2ft. 9½ in. and 2ft. 10½ in. A shows the "billiard spot," on the centre line, 12¾ in. from the top cushion; C, the "centre spot," in the centre of the table, and B the "pyramid spot," midway between A and C: XY is the "bulk line," and D the "D"

American professors, giving undivided attention to cannons and not being permitted to use the *push-stroke*, arrived at a perfection in controlling or "nursing" the balls to which English players could not pretend; yet the principles involved in making a long series of cannons were applied, and leading professionals soon acquired the necessary delicacy of touch. The plan is to get the three balls close to each other, say within a space which a hand can cover, and not more than from 4 to 8 in. from a cushion. The striker's ball should be behind the other two, one of which is

nearer the cushion, the other a little farther off, and farther forward. The striker's ball is tapped quietly on the one next the cushion, and hits the third ball so as to drive it an inch or two in a line parallel to the cushion. The ball first struck rebounds from the cushion, and at the close of the stroke all three balls are at rest in a position exactly similar to that at starting, which is called by the French *position mère*. Thus each stroke is a repetition of the previous one, the position of the balls being relatively the same, but actually forming a series of short advances along the cushion. With the push-stroke a great number of these cannons could be quickly made, say 50 in 3½ minutes; and, as that means 100 points, scoring was rapid. Most of the great spot-barred breaks contained long series of these cannons, and their value as records is correspondingly diminished, for in such hair-breadth distances very often no one but the player, and sometimes not even he, could tell whether a stroke was made or missed or was foul. Push-barred, the cannons are played nearly as fast; but with most men the series is shorter, *massé* strokes being used when the cannon cannot be directly played.

The Championship.—When Kentfield declined to play in 1849, John Roberts, sen., assumed the title, and held the position till 1870, when he was defeated by his pupil W. Cook. From 1870-85 the championship was shared by W. Cook, J. Roberts, jun., and J. Bennett.

LATER DEVELOPMENTS

From 1885 to 1899 John Roberts occupied a position in billiards which no other man has occupied in any game before or since, a position higher even than that of W. G. Grace in the cricket field. There was nobody to approach him. He made his own circle and remained impregnable in the centre of it. Men like W. J. Peall, Mitchell, North, Diggle, Richards, Shorter, all fine performers, stood no chance with him, even with a start of a quarter of the game. Moreover, it was not alone the superiority of his execution. He created his own atmosphere wherever he played, but especially in his headquarters at the Egyptian Hall in Piccadilly. Men spoke of "going to see Roberts," not of going to see billiards. He used to play games of 24,000 up, necessitating his making 1,000 at each session, against all comers, giving starts ranging from eight to ten thousand. At length he issued a challenge to give any man in the world half the game start. W. J. Peall was, according to the rules in force, quite as incontestably champion as Roberts himself was at the spot-barred game, which the latter had invented, rightly foreseeing that the spot-stroke was killing the game from a spectacular point of view. Peall took up the challenge and won by a considerable margin, though in the course of the game there had been times when it seemed as though Roberts might pull through after all.

About this time another reformer appeared in the world of billiards, though this time an amateur. Mr. Sydenham Dixon took great interest in performers, and performances, rules and regulations, and seeing clearly that the game was in need of a governing body, he founded the Billiard Association of which he finally became president, remaining so until its amalgamation with the Billiards Control Council in 1919. It may safely be said that no man has done more for the game. Broad-minded, with a sense of justice and fair play for all, he possessed a strength of character which led to many a clash with anyone attempting to control the game to his own advantage from the professional point of view, from John Roberts to Melbourne Inman and Smith. Roberts would have nothing to do with any championship other than one of his own arrangement. The other professionals regarded it as hopeless to contend against him. Not so Mr. Dixon, who actually ignored him and started the Billiard Association championship in 1889. He soon found many professionals eager to play for it, carrying as it did amongst other prizes, an income of £100 a year to the holder. Roberts, however, remained aloof, an unfortunate state of affairs, for he could certainly, at that time, have given substantial starts to many of the holders, and the Egyptian Hall remained the principal attraction.

Roberts was the very Beau Brummel of the game. His good looks and his bow to his audience as he led the way into his hall combined to make a picture which those who saw it will never

forget. And though for the sake of the game Mr. Dixon ignored him, no one in reality admired him more. Years alone could overcome him, and as his beard grew grey he dropped slowly out of the game at which he was still supreme. The idea of his taking a start from anyone was simply not to be contemplated. He had long searched for a possible successor, and pitched first on Stevenson and later on Tom Newman, taking the latter off on world tours until the boy came nearly to Roberts' standard by the time death removed the supreme billiard genius of more than a quarter of a century.

Dawson stood out as his successor. Had not Roberts consented to play a level match with the sturdy Yorkshireman? But Stevenson was close alongside. In style the two were widely opposed, the latter dainty and dapper in play as in person, the former, more square-fronted with less intricate methods. But at the very moment Dawson had gained his objective, fate struck him down with an affection of the eyes which completely put an end to his billiards. This left Stevenson champion under Billiard Association rules. He was satisfied in his own mind that he could now beat Roberts and that a victory over him would set his reputation on a pedestal. Very naturally Roberts considered that he had everything to lose and nothing to gain by a level match, and consented to play only if the younger man took a start of 2,000 points in 18,000. Rather than not have a match at all Stevenson agreed, and one of the most famous games in the history of billiards followed. Moreover, before the end of the first week all Stevenson's start had gone and the apparently still invincible veteran had the game won. But just when all men cried that he was beaten, the younger player took the bit between his teeth, caught up and passed his formidable rival and in the end won a great victory. So tremendously had Stevenson been oppressed by the sense of the meeting, by the atmosphere of Roberts' following, and their air of certainty of his superiority, that until the game was practically lost he could not find his touch. Stevenson 18,000; Roberts 16,480.

This victory left Stevenson, a very young man, apparently champion for a decade. At this point an unexpected figure emerged from the crowd, Melbourne Inman. Son of a professional player he had played with success most of the third class, and even these successes were gained to everyone's astonishment. His position at the table, cue delivery, and clumsy method of waving his cue about in an amateurish style to the danger of the lights and the markers' eyes, as though trying to assist his ball to go where he had designed to send it, gave no sort of impression that he was a future champion. None the less, he worked his way through the second class as surely as he had done through the third, principally by means of intense pains and regard for safety tactics, together with the British attribute of not knowing when he was beaten, and a certain number of close watchers of the game, among them the president of the Billiard Association, were not surprised when he challenged for the championship and in 1908 won it. Inman literally wore his opponents down. They became depressed and unable to produce their best. Time after time, after waiting while Inman had made 50 or 60 most laboriously, they went to the table to find themselves confronted with hopeless situations, when the stroke, itself intensely difficult, implied, in case of failure, another easy leave for another heavy-handed effort. Of course Inman soon rid himself of his poor style, till he became the master of technique and smooth action that he was at his zenith; but compared with his other great rivals, Stevenson and Reece, it still appeared long odds on either of them, although Reece was nearly always beaten. Reece once won a game in Australia, and in 1927 won another by means of the pendulum cannon. Style is by no means a criterion of scoring ability, delightful as it is to watch.

The trio remained for some time in a class by themselves until the composition-ball, losing-hazard artist, George Gray, appeared in 1910. Until his defeat at the hands of Smith, then almost unknown, and in receipt of a considerable start, Gray was regarded as unconquerable; with composition balls indeed he was. However, in the 1914 championship, played with ivory balls, he was beaten by Reece. This was a memorable championship, for the game which had been all Roberts till it became Dawson-Steven-

son, and turned later into Inman-Stevenson-Reece, now became Newman-Smith, with Davis threatening their heels (1921). Breaks, owing to changes in rules, freak cannons, etc., are difficult to compare, but with composition balls in Australia Walter Lindrum made a run of 1,879, second only to Gray's unfinished 2,000 effort. In 1927 the ivory ball record was held by Newman with a break of 1,370. Davis, Newman and Smith were at this time the only other players who had made runs of four figures with ivory balls. In other respects the game has undergone little change in the last 50 years so far as the implements are concerned.

None the less, billiards began to lose its hold on the public after the World War. With the exception of *The Times*, and such papers as are confined to sport, it was very poorly reported, many journals ignoring it altogether, though there was a monthly paper entirely devoted to it, *The Billiard Player*. There was very little money in the game in 1927 for any but those absolutely at the head of the profession. Except the halls provided by the billiard-table makers there was no place where it could be seen except during the championship. This development is the more strange in view of the fact that the popularity of the game as a pastime for amateurs increased during the same period. Great numbers of halls sprang up throughout the country, holding 20 or 30 tables, every one of which found users at certain times of the day, whilst snooker, as a rival game, could be seen even oftener than billiards. Long matches, sometimes of a fortnight's duration, are perhaps an explanation of the decline. New methods are certainly called for.

But if things from a professional point of view were not particularly cheerful in this period, the case was quite the contrary among the amateurs, who, being much more amenable to discipline, were easier to manage than the professionals. Their championship never caused any trouble to the governing body. The first was held in 1888 and was won by Mr. H. A. O. Lonsdale, a player with a beautiful style who came out and won it again in 1910, after an interval of 20 years or more. For a little while there were two amateur championships. One, the original, under the rules of the Billiard Association: the other under those of the Billiards Control Council. Happily for the game these ultimately became one body with a strong, hard-working committee whose whole concern was the betterment of the game.

The difference in play between the best amateurs and the best professionals is marked; it is natural that those whose living depends on their ability should excel those not so dependent. The latter devote only an hour or two daily to play and less to practice; the former make the game their business, especially devoting many hours a day to practice. Another good reason for the superiority of the professional is that he continually plays for a week or a fortnight on the same table, with his own cues, and the same set of balls. Contrast this with the ordinary amateur's play. He goes from table to table, each one differing in strength, in cushions and in cloth, sometimes finding himself faced with composition, sometimes with ivory balls, and with indifferent cues except in his club or when playing on his own table at home. How can he be expected to give any idea of his merit when asked to play after such mixed experiences?

The professional, of course, takes up a position that is easily intelligible, for it is naturally based upon financial considerations. In every professional question that is only to be expected and may be sympathized with, but what cannot be so treated is the professional's claim for exemption from the control of governing bodies, and his desire to rely solely on the power of the press. An exception must be made in the case of Newman, the 1927 champion. He competed for the title without a grumble and became a strong favourite with the public in consequence. In 1928 Davis beat him in the championship and succeeded him as title-holder.

The outstanding figure amongst amateurs in the beginning was Mr. A. P. Gaskell, who, however, relied for his predominance on his ability at the spot-stroke. He won the championship five times. In those days more than one championship was played for annually, a match taking place whenever a challenger appeared. Mr. Christy was another great exponent of the spot-stroke, by means of which rumour credits him with at least one four-figure break, and there were a good many professionals then who could not claim that.

The changed rules applied equally to amateurs as to professionals with the result that new names sprang into prominence. Messrs. Fry (8), Virr (6) and Graham Symes (3) between them won 17 championships. Mr. Fry's eight victories were won during an interval of 32 years—1893–1925. Mr. G. Symes only gave up competing when the composition balls came into use. Many winners of the amateur championship subsequently became professionals, amongst them Courtenay, Lovejoy, Breed and Earlam. It is often

FRENCH BILLIARD TABLE
Both French and American billiards are played on a pocketless table. Only cannons are played, each scoring one point

said that there are plenty of amateurs about the West End clubs who could easily beat those who compete in the championships, but Mr. Fry's excellent book states that in his lengthy experience he has only known two amateurs who would have held much chance of winning the open trophy—Messrs. H. R. Rimington-Wilson, and Douglas Lane. The former is said to have played a level match against Mitchell at his best and beaten him, and the latter was endowed with power of cue and eye which enabled him to make strokes equal to those of the very best professionals. In a previous generation there was a similarly gifted amateur of the name of Rogers.

There is one game on the billiard table at which a few amateurs can hold their own against the professionals—snooker. No professional had made a break of 100 up to 1927, but this was done by an amateur, whilst some of the latter have gone far in the Open Snooker championship. The game has become exceedingly popular, more so than billiards itself, especially in the north of England and Scotland. In 1928 Davis made a hundred break.

An Empire amateur billiard championship was started in 1925, representatives from England, Scotland, Ireland, Australia and South Africa taking part. This was won by Earlam who then turned professional. It is questionable whether those who intend taking up the game professionally should be allowed to play in amateur events. They might easily be excluded without giving any offence by all the players having to sign a statement that they had no intention of turning professional for at least five years.

In 1927 the Empire amateur championship was won by South Africa, represented by Mr. Allan Prior.

Winners of championships, professional and amateur, from the year 1900, were:—

Professional.	Amateur
1901—C. Dawson.	1900—S. H. Fry.
1901—H. W. Stevenson.	1901—S. S. Christy.

AMERICAN BILLIARDS

The game of American billiards is played on a table without pockets. It is called a carom table and is of two sizes, one 4½ by 9 ft. and the other, 5 by 10 feet. For the carom game three balls are used, one red, one plain white and one white with a black dot. In the four ball game, played by the less expert, there are two red balls and two white balls.

Three Ball Game.—The red ball in the three ball game is placed on the foot section of the table on a spot at the middle of a line drawn across the table at a right angle from the second diamond on each long rail, and one white ball is placed on a corresponding spot at the head of the table. An imaginary line drawn across the head of the table at right angles to the second diamond on each long rail is termed the "string." In what would be the centre of this line a spot is placed, known as the head spot. The game is begun by "stringing" for the lead, banking from the head to the foot rail and back. The player whose ball settles nearest to the head rail wins the choice of white balls and the right to elect whether to lead or to make his opponent lead. Should the two white balls come in contact when stringing for lead, the player whose ball is clearly out of its true course or whose ball strikes the red ball when that ball is on its proper spot, forfeits the lead. When the contact of the balls is equally the fault of both players or when the balls come to rest at an equal distance from the head cushion, the players string again. Contestants play in rotation until a specified number of points constituting a game is completed. The player leading must place his ball inside the string and within six inches to the right or left of the other white ball and must make the cue ball strike the red ball in order to effect a count. On any other than the opening shot, excepting when the balls are for any reason spotted, the striker may play upon either ball. Each carom counts one point. A ball forced off the table is spotted on its proper spot. If the spot is occupied by another ball the ball forced from the table is placed on one of the other spots. A foul ends an inning. No points are counted on foul strokes.

In the three ball straight rail carom game the crotch is barred. The object balls are considered crotched wherever the centres of both lie within a 4½ in. square at either corner of the table, and when so crotched but three counts are allowed unless one or both object balls be forced out of the crotch. In case of failure the player's hand is out and his opponent plays with the balls as he finds them. In the four ball game a carom counts one, but in case of a carom on both object balls the player counts two.

14.2 Balk Line Game.—To mark the table properly for 14 in balk line the lines are drawn on a 5×10 table from each of the first diamond sights on the end and side rails to the corresponding diamond sight on the opposite end or side rail. The large centre space on the table is not a balk space. The object balls are in balk whenever both have stopped within any one of the balk spaces. The marker then calls "in" and when one or both object balls are driven out of balk space, the marker calls "out." A ball on the line is in balk. A ball is on the line only when its centre or point of contact with the table touches this line. When two object balls are on the same line the striker shall have the option to determine in which balk they are to be called, and must govern his play accordingly. But two shots are allowed when two object balls are within the same balk space, hence the name 14.2 balk line. If at least one of the object balls is not driven out of balk on the second shot the shot is void and the player's hand out.

18.2 Balk Line Game.—The game of 18.2 balk line is played on a 5×10 table and the balk lines are drawn 18 in. from the edges of the cushions with eight anchor spaces on each table. These anchor spaces measure seven inches square. Two each are located on the head rail and on the foot rail and two each on the side rails with the 18 in. balk line across the ends of the table as a centre. The general rules of 18.2 balk line are somewhat similar to those of the 14.2 balk line game. The object balls are considered to be in anchor when the centres of both balls lie in one of the anchor spaces. When the balls are anchored the striker may have two consecutive shots, but if he fails on the second shot to force one or both of the object balls outside the anchor space, the second shot is void and the opponent plays the balls as he finds them. There is also an 18.1 balk line game in which but one shot is allowed in balk and one in anchor. It is claimed for the 18.1 balk line game that it is the medium by which the highest skill of both professional and amateur can be measured. After Frank Ives had won the 14.2 balk line championship in 1892 it was agreed the game had become too easy. Experiment began and the new game of 18.2 was invented. In 1896 Maurice Daly held the first 18.2 championship in New York City, Ives, Schaefer and Garnier competing. The game was for 500 points, five shots allowed in anchor. The anchor spaces were 3½ by 7 inches.

In 1903 the first world tournament at 18.2 was played in Paris. Vignaux was awarded the championship by a decision based upon grand averages. Sutton and Slosson, representing the United States, played against him. Sutton challenged Vignaux and lost to him, 1904, by 496 to 500. Since then all 18.2 tournaments have been played in the United States. George F. Slosson won in New York in 1906, losing to Sutton only. Sutton challenged and won from Slosson the same year. Sutton was challenged but held the title to 1908, when he lost to Hoppe on the latter's second challenge. Hoppe resigned the title. Successive winners were Morningstar, 1909; Demarest, the same year; Hoppe, 1912; at 500 points. In 1919 the anchor spaces were enlarged to seven inches square and the total of points reduced to 400. Hoppe won the tournament and also that of 1920. In the eighth tournament in 1921 Jacob Schaefer, Jr., not only won the championship played for in Chicago, but established a single average of 200, grand average of 51.23, and tied Hoppe in games, winning the play off, 400 to 26. Schaefer defeated Cochran 400 to nothing in their game. Hoppe won in 1922 and 1923 in New York City. In 1925 the most remarkable billiard tournament in history was played in Chicago. Schaefer, Jr., won the title again, being undefeated in five games. Schaefer won the seventh of the series from Hagenlacher by winning the bank and making 400 points and game without miss. In the closing game between Hoppe and Schaefer, the latter entered the eighth inning 296 points behind and ran the game out. His grand average was 57.14, a world's record to add to the single average records. Cochran won in 1927 and in his challenge match with Erich Hagenlacher established a high record run of 407 points in one inning.

Development of Game.—Tom Foley, an American authority on billiards, dates the real start of the game in the United States from the year 1859. The first national match was played at Detroit, Mich., April 12, 1859. John Seereiter of Detroit and Michael Phelan of New York City were matched for a stake of \$15,000 and the championship of America. The game was for 2,000 points, caroms, with four balls and 6×12, six-pocket table, pushing and crotching allowed. Phelan won 2,000 to 1,904 for Seereiter. The winner's best run was 129 and his average 12-32-164. Phelan was declared the first billiard champion of America and returned to New York in triumph where he reigned as champion through 1860, 1861 and 1862. Dudley Kavanaugh was champion in 1863, 1864 and 1865, to be succeeded the latter year by Louis Fox and John Deery. In 1866 Deery and Joe Dion were champions. In 1867 the champions were Joe Dion and John McDevitt, the latter again in 1868. Beginning in 1869 the championship was played for at four ball caroms on a 5½×11 pocket table, pushing and crotching barred, single caroms counting 3 and double caroms 6, for 1,200 points. John Deery was champion that year and in 1870, until

he lost to A. P. Rudolphe. In 1871 the championship was held by Frank Parker and Cyrille Dion. The latter was undisputed champion in 1872 but in 1873 was succeeded by Maurice Daly and Albert Garnier. In 1874 the champions were Maurice Vignaux and Joe Dion. In 1876 the rules were changed to what were called straight rail play, three balls, on a 5×10 carom table. William Sexton was champion in 1876-77-78. Following him began the long reign of Jacob Schaefer, Sr., known as the "Wizard," who was champion in 1879-80-81-82. In 1883 the 5×10 table was in use with an eight inch balk line to prevent nursing. Schaefer won in 1883-84. In 1885 the balk line was widened from 8 to 14 inches. Slosson won from Schaefer and then lost. The

FULL SIZE AMERICAN POCKET BILLIARD TABLE WITH DIMENSIONS
The pocket billiard table differs from the standard billiard table in that it is equipped with six pockets into which the fifteen balls of the game are played

latter was champion in 1886-87-88-89 and 1890. From then until 1897 no championship was played for. Champions at 18.1 have been George Slosson in 1897, Jacob Schaefer and Frank Ives, 1898; W. F. Hoppe, 1906; Geo. B. Sutton, W. F. Hoppe and Jacob Schaefer, Sr., 1907; George Slosson and George B. Sutton, 1908 and W. F. Hoppe, 1910, since which year no championship has been contested. Champions at 18.2 balk line have been Jacob Schaefer from 1901-05; Slosson and Sutton, 1906; Sutton, Hoppe and Schaefer, Sr., 1907; Slosson and Sutton, 1908; Morningstar and Demarest, 1909; Hoppe from 1910-20; Schaefer, Jr., 1921; Hoppe from 1922-25; Schaefer, Jr., 1925; Cochran, 1927. The amateur champions at 14.2 were Martin Mullen in 1899, Wilson P. Foss, 1900; C. Fred Conklin, 1901; Arthur R. Townsend, 1901; Chas. Norris, Wilson P. Foss, Edward W. Gardner, 1902; Wilson P. Foss, 1903; J. Ferdinand Poggenburg, 1904; C. Fred Conklin, 1905; Edward W. Gardner, 1906; Calvin Demarest, 1907-08. The invention of the balk line game is attributed by Tom Foley to M. Bensinger, early head of The Brunswick-Balke-Colender company. He undertook to devise a system of lines to be drawn upon the surface of the table that might handicap Schaefer, at that time the leading billiard player of the world and thus make other players his possible equal. In consultation with Charles E. Mussey, T. Z. Cowles and Foley he evolved the eight inch balk line game in 1883. A tournament was held under the new rules in Chicago in that year. Following the eight inch lines, which were quickly discovered not to be severe enough, came the 14in. and then the 18in. balk lines.

Three Cushion Carom.—About 1910 the three cushion carom game began to attract attention in the United States and in 1912 the first three cushion carom championship tournament was held and John Horgan won. Subsequent champions have been Alfredo De Oro, George Moore, A. Kieckhefer, John Layton, Tiff Denton and R. L. Cannefax. A valid three cushion carom is effected by making the cue ball touch three cushions before striking the second object ball. Three cushions mean three impacts. The number of cushions does not mean three different cushions as a count may be executed on one cushion. Each carom counts one. When the cue ball rests on a cushion the striker can play directly at that cushion but that shall not count as an impact. In case the balls are frozen (i.e., in contact) the striker has the option of playing away from the ball with which the cue ball is in contact or having the balls spotted as at the opening of the game. This

game is one that calls for power of stroke, as well as delicacy and is more intricate than other games because of the demand upon the player for accurate knowledge of cushion angles.

Pocket Billiards.—Fifteen ball pool is known in the United States as pocket-billiards. Championships have been won by Gottlieb Wahlstrom, Albert Frey, J. L. Malone, Peter Rodgers, Alfredo De Oro, Frank Sherman, William Clearwater, K. Stofft, Thomas Hueston, John Horgan, Charles Weston, Jerome Keogh, Ben Allen, W. E. Blankenship, Frank Taberski, Ralph Greenleaf. The game is played on a six pocket table with 15 object balls, continuous pocketings being the rule. The cue ball is white and the 15 balls are red in colour. The object balls are numbered. The player calls the number of the ball and the pocket into which he will drive it. When 14 object balls are pocketed, they are set up in triangular form with the apex vacant and the striker is allowed to proceed as long as he can legally pocket a ball. If other balls than those called are pocketed he is entitled to them.

BILLING MACHINE: see OFFICE APPLIANCES.

BILLINGS, JOHN SHAW (1839-1913), American surgeon and librarian, was born in Switzerland county, Ind., on April 12, 1839. He graduated at Miami university in 1857 and at the Medical College of Ohio in 1860. During the Civil War he served as a surgeon in the field and in hospitals from 1861 to 1864 when he entered the surgeon-general's office in Washington. In this position he had charge of the Army medical museum and library, and developed the latter into one of the largest medical libraries in the world, for which he prepared an unusually valuable index-catalogue. In 1896 upon the consolidation of the Astor and Lenox libraries and the Tilden Trust into the New York Public library, he became its first director and displayed marked constructive capacity in this position until his death which occurred in New York city on March 11, 1913. Among his published works are *Mortality and Vitality Statistics of the United States* (1885); *National Medical Dictionary* (1889); *Some Library Problems of Tomorrow* (1902); and *Physiological Aspects of the Liquor Problem* (1903).

BILLINGS, a city in southern Montana, U.S.A., on the Yellowstone river, 3,000ft. above sea-level; the county seat of Yellowstone county. It is on the Yellowstone trail, the Custer battlefield, and the National parks highways, and is served by the Burlington, the Great Northern, and the Northern Pacific railways. The population was 3,221 in 1900; 15,100 in 1920; and about 17,500 in 1927. It is the metropolis of the "midland empire," a productive region of Montana and Wyoming, which already contains 2,000,000 acres of irrigated land. Sugar beets, wheat, wool and live stock are the leading products in the immediate vicinity, and there is a factory which makes 90,000,000lb. of beet sugar a year. The city has 70 manufacturing and wholesale establishments, and is the trading centre of an area as large as the State of Minnesota. Shipments of live stock, flour, sugar, grain, hay, wool, beans, potatoes, butter, and eggs amount to over \$10,000,000 annually. Natural gas is used. The Eastern Montana Normal school, Polytechnic institute and the first orthopaedic hospital in the North-west are situated here.

Billings is the gateway to the Beartooth national forest, one of the wildest and most picturesque regions in the North-west, in which is Grasshopper glacier, with millions of grasshoppers embedded in its ice. On the outskirts is the State fish hatchery. There are many vacation resorts in and near the forest, including numerous "dude ranches," which offer tenderfoot visitors the pleasures of western life without its hardships.

BILLINGS-CODY WAY, a thoroughfare extending from Billings, Mont., to Cody, Wyoming. It is about 130m. in length. Touching upon Laurel, Bridger and Powell, it passes by the Pryor

mountains and furnishes interesting scenery along its entire course.

BILLINGTON, ELIZABETH (c. 1768–1818), British opera-singer, was born in London, her father being a German musician named Weichsel, and her mother a popular singer. She was a precocious child, and received a solid-musical training from her father. Before she was twelve she had published two volumes of pianoforte sonatas. In 1783 she contracted an unfortunate secret marriage with James Billington, a double-bass player in the Drury lane orchestra. With him she went to Dublin where she made her first stage appearance as Eurydice. In London she made a sensation (Feb. 13, 1786) in the part of Rosetta in Arne's *Love in a Village*. She then went to Paris to study under Sacchini, and throughout her career was a serious student. In 1794 she and her husband went to Italy, and Mrs. Billington appeared at Naples in a new opera, *Inez di Castro*, written for her by F. Bianchi, and then at Florence, at Venice and at Milan. Her husband died suddenly during the tour, and in 1799 she married a Frenchman named Féliassent. The second marriage was even more unfortunate than her first. Féliassent ill-treated her, and she left him in 1801. In 1817, however, she returned to him, and died the next year, on Aug. 25, at St. Artien, near Venice. According to some accounts her death was caused by a blow received from her husband. Mrs. Billington sang regularly at Covent garden and Drury lane from 1801 to 1810. Accounts vary of the quality of her voice and of her acting, but there is unanimous testimony to the finished character of her art. There are many portraits and engravings of her, including Sir Joshua Reynolds's picture of her as St. Cecilia.

BILLITON (Dutch, BLITOENG), island, Dutch East Indies, between Banka and Borneo and separated respectively by the Gaspar and Karimata straits. It forms an assistant-residency, under Sumatra. Roughly square in shape, it is 55m. long by 43 wide, and its area is 1,860sq.m. Included with it are 135 small adjacent islands with an area of 95sq.m., which are separated by narrow and mostly unnavigable channels. In physical structure and products it resembles Banka. Its coasts are sandy and very marshy, and though in the centre of the island a height of 1,670ft. is reached (Mt. Tanjem), most of the land lies less than 130ft. above sea-level, with groups of hills of granite or sedimentary formation rising from the flat or slightly undulating country; in the central parts there are treeless plains, covered with alang-alang grass. The geological formation is Devonian and granitic, with laterites. The average mean annual rainfall is 114.5in., with an average of 192 rainy days; the average mean temperature is 77°. Billiton, like Banka, has extensive tin deposits and forms the southern limit of the occurrence of this metal. The mines are worked largely by electrical power, with Chinese coolie labour, and by a private company, Government taking ½ths of the profits. In 1925–26, 162,700 piculs of tin were produced (1 picul=136.23lb.). Trepan, tortoises, and edible birds' nests are found along the coast, and the woods yield timber for boat-building, and gum. Other products are coconuts and sago. Imports (1925), 4,420,389; exports, 34,228,054 gulden.

The population of Billiton is 62,979, 23,299 being foreign Asiatics, largely Chinese. The aborigines (Mohammedans, with some pagan beliefs) are akin to those of Banka, resembling the Bataks of Sumatra; on the coast there are *Orang laut*, or seagypsies. The coast is a difficult one, beset with rocks and coral banks, but one river, the Cheruchup, is 1,300 to 1,600ft. wide at its mouth (barred by a sandbank), and is tidal for seven miles and navigable as far as Cheruchup village. The best harbour is that of Tanjong Pandan, the capital of Billiton (4,800), on the west coast. Billiton was formerly under the Sultan of Palembang, Sumatra, by whom it was ceded to the British in 1812. In the treaty of 1814, between the British and the Dutch, no mention was made of it, and the British at first refused to cede the island, only recognizing the Dutch claim in 1824.

BILLITONITE: see **TEKTITE**.

BILL OF EXCHANGE, a form of negotiable instrument, defined below, the history of which, though somewhat obscure, was ably summed up by Lord Chief Justice Cockburn in his judgment in *Goodwin v. Roberts* (1875), L.R. 10 Ex. pp. 346–358. Bills of exchange were probably invented by Florentine

Jews. They were well known in England in the middle ages, though there is no reported decision on a bill of exchange before the year 1603. At first their use seems to have been confined to foreign bills between English and foreign merchants. It was afterwards extended to domestic bills between traders and finally to bills of all persons, whether traders or not. But for some time after they had come into general employment, bills were always alleged in legal proceedings to be drawn *secundum usum et consuetudinem mercatorum*. The foundations of modern English law were laid by Lord Mansfield with the aid of juries of London merchants. No better tribunal of commerce could have been devised. Subsequent judicial decisions have developed and systematized the principles thus laid down. Promissory notes are of more modern origin than bills of exchange, and their validity as negotiable instruments was doubtful until it was confirmed by a statute of Anne (1704). Cheques are the creation of the modern system of banking.

From 2,600 cases scattered over some 300 volumes of Reports and 17 Statutes dealing with isolated points the English law relating to Bills of Exchange, promissory notes, and cheques was codified by the Bills of Exchange Act 1882 which laid down, with one exception applicable only to Scotland, uniform rules for Great Britain and Ireland. Two salient characteristics distinguish negotiable instruments from other engagements to pay money. In the first place, the assignee of a negotiable instrument, to whom it is transferred by indorsement or delivery according to its tenor, can sue thereon in his own name; and, secondly, he holds it by an independent title. If he takes it in good faith and for value, he takes it free from "all equities," that is to say, all defects of title or grounds of defence which may have attached to it in the hands of any previous party. These characteristic privileges were conferred by the law merchant, which is part of the common law, and are now confirmed by statute.

Definition.—By s. 3 of the Act a bill of exchange is defined to be an unconditional order in writing "addressed by one person to another, signed by the person giving it, requiring the person to whom it is addressed to pay on demand or at a fixed or determinable future time a sum certain in money to or to the order of a specified person, or to bearer."¹ The person who gives the order is called the drawer. The person thereby required to pay is called the drawee. If he assents to the order, he is then called the acceptor. An acceptance must be in writing and must be signed by the drawee. The mere signature of the drawee is sufficient (s. 17). The person to whom the money is payable is called the payee. The person to whom a bill is transferred by indorsement is called the indorsee. The term "holder" includes any person in possession of a bill who holds it either as payee, indorsee or bearer. A bill which in its origin is payable to order becomes payable to bearer if it is indorsed in blank. If the payee is a fictitious or non-existing person the bill may be treated as payable to bearer (s. 7). A payee is a fictitious person if his name is inserted by way of pretence merely, *i.e.*, with no intention that payment should be made to him (*Bank of England v. Vagliano* [1891] A.C. 107).

The following is a specimen of an ordinary form of a bill of exchange:—

£100.

LONDON, 1st January, 1901

Three months after date pay to the order of Mr. J. Jones the sum of one hundred pounds for value received.

Brown & Co.

To Messrs. Smith & Sons, Liverpool.

A bill in its origin was a device to avoid the transmission of cash from place to place to settle trade debts. Now a bill of exchange is a substitute for money. It is immaterial whether it is payable in the place where it is drawn or not. It is immaterial whether it is stated to be given for value received or not, for the law itself raises a presumption that it was given for value. But though bills are a substitute for cash payment, and though they

¹This is also the definition given in the United States, by s. 126 of the general Act relating to negotiable instruments, prepared by the conference of State commissioners on uniform legislation, which has been universally adopted.

constitute the commercial currency of the country, they must not be confounded with money. No man is bound to take a bill in payment of debt unless he has agreed to do so. If he does take a bill, the instrument ordinarily operates as conditional, and not as absolute payment. If the bill is dishonoured the debt revives. Under the laws of some Continental countries, a creditor, as such, is entitled to draw on his debtor for the amount of his debt, but in England the obligation to accept or pay a bill rests solely on actual agreement. A bill of exchange must be an unconditional order to pay. If an instrument is made payable on a contingency, or out of a particular fund, so that its payment is dependent on the continued existence of that fund, it is invalid as a bill, though it may of course avail as an agreement or equitable assignment. In Scotland it has long been the law that a bill may operate as an assignment of funds in the hands of the drawee, and s. 53 of the Act preserves this rule.

Bills of exchange must be stamped, but the Act of 1882 does not regulate the stamp. It merely saves the operation of the stamp laws, which necessarily vary from time to time according to the fluctuating needs and policy of the exchequer. Under the Finance Act 1918, bills payable on demand and three-day bills are subject to a fixed stamp duty of twopence. The stamp may be impressed or adhesive. All other bills are liable to an *ad valorem* duty. All other inland bills must be drawn on impressed stamp paper, but foreign bills, of course, can be stamped with adhesive stamps, if the stamp is affixed before the bill is negotiated in England. English law does not concern itself with foreign revenue laws. It is immaterial whether a bill drawn abroad is stamped in accordance with the law of its place of origin or not. On arrival in England it has to conform to the English stamp laws.

A bill of exchange is payable on demand when it is expressed to be payable on demand, or at sight, or on presentation, or when notice for payment is expressed. In calculating the maturity of bills payable at a future time, three days, called days of grace, must be added to the nominal due date of the bill. For instance, if a bill payable one month after sight is accepted on Jan. 1, it is really payable on Feb. 4, but when the last day of grace falls on Sunday, Christmas day, Good Friday, or a day appointed by Royal Proclamation as a public fast or thanksgiving day, the bill is due and payable on the preceding business day. On the other hand on Bank holidays (other than Christmas day or Good Friday), or when the last day of grace is a Sunday and the second day of grace a bank holiday, the bill is due and payable on the succeeding business day (s. 14).

Acceptance.—By the acceptance of a bill the drawee becomes the principal debtor on the instrument and the party primarily liable to pay it. The acceptor of a bill "by accepting it engages that he will pay it according to the tenor of his acceptance," and is precluded from denying the drawer's right to draw or the genuineness of his signature (s. 54). The acceptance may be either general or qualified. As a qualified acceptance is so far a disregard of the drawer's order, the holder is not obliged to take it; and if he chooses to take it he must give notice to antecedent parties, acting at his own risk if they dissent (ss. 19 and 44). The drawer and indorsers of a bill are in the nature of sureties. They engage that the bill shall be duly accepted and paid according to its tenor, and that if it is dishonoured by non-acceptance or non-payment, as the case may be, they will compensate the holder provided that the requisite proceedings on dishonour are duly taken. Any indorser who is compelled to pay the bill has the like remedy as the holder against any antecedent party (s. 55). A person who is not the holder of a bill, but who backs it with his signature, thereby incurs the liability of an indorser to a holder in due course (s. 56). An indorser may by express term either restrict or change his ordinary liability as stated above. *Prima facie* every signature to a bill is presumed to have been given for valuable consideration. But sometimes this is not the case. For friendship, or other reasons, a man may be willing to lend his name and credit to another in a bill transaction. Hence arise what are called *accommodation bills*. Ordinarily the acceptor gives his acceptance to accommodate the

drawer. But occasionally both drawer and acceptor sign to accommodate the payee, or even a person who is not a party to the bill at all. The criterion of an accommodation bill is the fact that the principal debtor according to the instrument has lent his name and is in substance a surety for someone else. The holder for value of an accommodation bill may enforce it exactly as if it was an ordinary bill, for that is the presumable intention of the parties. But if the bill is dishonoured the law takes cognizance of the true relations of the parties, and many of the rules relating to principal and surety come into play. Suppose a bill is accepted for the accommodation of the drawer. It is the drawer's duty to provide the acceptor with funds to meet the bill at maturity. If he fails to do so he cannot rely on the defence that the bill was not duly presented for payment or that he did not receive due notice of dishonour. If the holder, with notice of the real state of the facts, agrees to give time to the drawer to pay, he may thereby discharge the acceptor.

Holder in Due Course.—The holder of a bill has special rights and special duties. He is the mercantile owner of the bill, but in order to establish his ownership he must show a mercantile title. The bill must be negotiated to him, that is to say, it must be transferred to him according to the forms prescribed by mercantile law. If the bill is payable to order, he must not only get possession of the bill, but he must also obtain the indorsement of the previous holder. If the bill is payable to bearer it is transferable by mere delivery. A bill is payable to bearer which is expressed to be so payable, or on which the only or last indorsement is an indorsement in blank. If a man lawfully obtains possession of a bill payable to order without the necessary indorsement, he may obtain some common law rights in respect of it, but he is not the mercantile owner, and he is not technically the holder or bearer. But to get the full advantages of mercantile ownership the holder must be a "holder in due course"—that is to say, he must satisfy three business conditions. First, he must have given value, or claim through some holder who has given value. Secondly, when he takes the bill, it must be regular on the face of it. In particular, the bill must not be overdue or known to be dishonoured. An overdue bill, or a bill which has been dishonoured, is still negotiable, but in a restricted sense. The transferee cannot acquire a better title than the party from whom he took it had (s. 36). Thirdly, he must take the bill honestly and without notice of any defect in the title of the transferor—as, for instance, that the bill or acceptance had been obtained by fraud or threats, or for an illegal consideration. If he satisfies these conditions he obtains an indefeasible title, and can enforce the bill against all parties thereto. The Act substitutes the expression "holder in due course" for the somewhat cumbersome older expression "*bona fide* holder for value without notice." The statutory term has the advantage of being positive instead of negative. The French equivalent "*tiers porteur de bonne foi*" is expressive. Forgery, of course, stands on a different footing from a mere defect of title. A forged signature, as a general rule, is a nullity. A person who claims through a forged signature has no title himself, and cannot give a title to any one else (s. 24). Two exceptions to this general rule require to be noted. First, a banker, who in the ordinary course of business pays a demand draft held under a forged indorsement is protected (s. 60). Secondly, if a bill is issued with material blanks in it, any person in possession of it has *prima facie* authority to fill them up, and if the instrument when complete gets into the hands of a holder in due course the presumption becomes absolute. As between the immediate parties the transaction may amount to forgery, but the holder in due course is protected (s. 20).

Dishonour.—The holder of a bill has special duties which he must fulfil in order to preserve his rights against the drawers and indorsers. They are not absolute duties; they are duties to use reasonable diligence. When a bill is payable after sight, presentment for acceptance is necessary in order to fix the maturity of the bill. Accordingly the bill must be presented for acceptance within a reasonable time. When a bill is payable on demand it must be presented for payment within a reasonable time. When it is payable at a future time it must be presented

on the day that it is due. If the bill is dishonoured the holder must notify promptly the fact of dishonour to any drawer and indorser he wishes to charge. If, for example, the holder only gives notice of dishonour to the last indorser, he could not sue the drawer unless the last indorser or some other party liable has duly sent notice to the drawer. When a foreign bill is dishonoured the holder must cause it to be protested by a notary public. The bill must be noted for protest on the day of its dishonour. If this be duly done, the protest, *i.e.*, the formal notarial certificate attesting the dishonour, can be drawn up at any time as of the date of the noting. A dishonoured inland bill may be noted, and the holder can recover the expenses of noting, but no legal consequences attach thereto. In practice, however, noting is usually accepted as showing that a bill has been duly presented and has been dishonoured. Sometimes the drawer or indorser has reason to expect that the bill may be dishonoured by the drawee. In that case he may insert the name of a "referee in case of need." But whether he does so or not, when a bill has been duly noted for protest, any person may, with the consent of the holder, intervene, for the honour of any party liable on the bill. If the bill has been dishonoured by non-acceptance it may be "accepted for honour *supra* protest." If it has been dishonoured by non-payment it may be paid *supra* protest. When a bill is thus paid and the proper formalities are complied with, the person who pays becomes invested with the rights and duties of the holder so far as regards the party for whose honour he has paid the bill, and all parties antecedent to him (ss. 65 to 68).

Discharge.—Normally a bill is discharged by payment in due course, that is to say, by payment by the drawee or acceptor to the holder at or after maturity. But it may also be discharged in other ways, as for example by coincidence of right and liability (s. 61), voluntary renunciation (s. 62), cancellation (s. 63), or material alteration (s. 64).

A bill of exchange is the most cosmopolitan of all contracts. It may be drawn in one country, payable in another, and indorsed on its journey to its destination in two or three more. The laws of all these countries may differ. Provision for this conflict of laws is made by s. 72, which lays down rules for determining by what law the rights and duties of the various parties are to be measured and regulated. Speaking broadly, these rules follow the maxim *Locus regit actum*. A man must be expected to know and follow the law of the place where he conducts his business, but no man can be expected to know the laws of every country through which a bill may travel. For safety of transmission from country to country bills are often made out in sets. The set usually consists of three counterparts, each part being numbered and containing a reference to the other parts. The whole set then constitutes one bill, and the drawee must be careful only to accept one part, otherwise if different accepted parts get into the hands of different holders, he may be liable to pay the bill twice (s. 71). Foreign bills circulating through different countries have given rise to many intricate questions of law. But the subject is perhaps one of diminishing importance, as in many trades the system "cable transfers" is superseding the use of bills of exchange.

Cheques.—A cheque "is a bill of exchange drawn on a banker payable on demand" (s. 73). For the most part the rules of law applicable to bills payable on demand apply in their entirety to cheques. But there are certain peculiar rules relating to the latter which arise from the fact that the relationship of banker and customer subsists between the drawer and drawee of a cheque. For example, when a person has an account at a bank he is, as an inference of law, entitled to draw on it by means of cheques. A right to overdraw can, of course, only arise from agreement. The drawer of a cheque is not absolutely discharged by the holder's omission to present it for payment within a reasonable time. He is only discharged to the extent of any actual damage he may have suffered through the delay (s. 74). Apart from any question of delay, a banker's authority to pay his customer's cheques is determined by countermand of payment or by notice of the customer's death (s. 75). Of recent years the use of cheques has enormously increased, and they have now become the

normal machinery by which all but the smallest debts are discharged. To guard against fraud, and to facilitate the safe transmission of cheques by post, a system of crossing has been devised which makes crossed cheques payable only through certain channels. The first Act which gave legislative recognition to the practice of crossing was the 19 and 20 Vict. c. 95. That Act was amended in 1858, and a consolidating and amending Act was passed in 1876. The Act of 1876 is now repealed, and its provisions are re-enacted with slight modifications by ss. 76 to 82 of the Bills of Exchange Act 1882. A cheque may be crossed either "generally" or "specially." A cheque is crossed generally by drawing across it two parallel lines and writing between them the words "& Co." When a cheque is crossed generally it cannot be paid over the counter. It must be presented for payment by a banker. A cheque is crossed specially by adding the name of the banker, and then it can only be presented through that particular banker. A cheque, whether crossed generally or specially, may further be crossed with the words "not negotiable." A cheque crossed "not negotiable" is still transferable, but its negotiable quality is restricted. It is put on pretty much the same footing as an overdue bill. The person who takes it does not get, and cannot give a better title to it, than that which the person from whom he took it had. These provisions are supplemented by provisions for the protection of paying and collecting bankers who act in good faith and without negligence. Suppose that a cheque payable to bearer which is crossed generally and with the words "not negotiable" is stolen. The thief then gets a tradesman to cash it for him, and the tradesman gets the cheque paid on presentment through his banker. The banker who pays and the banker who receives the money for the tradesman are protected, but the tradesman would be liable to refund the money to the true owner. Again, assuming payment of the cheque to have been stopped, the tradesman could not maintain an action against the drawer.

Promissory Notes.—A promissory note is defined by s. 83 of the Act to be an "unconditional promise in writing made by one person to another, signed by the maker, engaging to pay on demand, or at a fixed or determinable future time, a sum certain in money to or to the order of a specified person or to bearer." A promissory note may be made by two or more makers, and they may be liable either jointly, or jointly and severally, according to its tenor (s. 85). For the most part, rules of law applicable to a bill of exchange apply also to a promissory note, but they require adaptation. A note differs from a bill in this; it is a direct promise to pay, not an order to pay. When it issues it bears on it the engagement of the principal debtor who is primarily liable thereon. The formula for applying to notes the rules as to bills is that "the maker of a note shall be deemed to correspond with the acceptor of a bill, and the first indorser of a note shall be deemed to correspond with the drawer of a bill payable to drawer's order" (s. 89). Rules relating to presentment for acceptance, acceptance, acceptance *supra* protest, and bills in a set, have no application to a note. Moreover, when a foreign note is dishonoured it is not necessary, for English purposes, to protest it. All promissory notes are subject to an *ad valorem* stamp duty. Inland notes must be on impressed stamp paper. Foreign notes are stamped with adhesive stamps. For ordinary legal purposes a bank-note may be regarded as a promissory note made by a banker payable to bearer on demand. It is, however, subject to special stamp regulations. It is not discharged by payment, but may be re-issued again and again. In the interests of the currency the issue of bank-notes is subject to various statutory restrictions. A bank, other than the Bank of England, may not issue notes in England unless it had a lawful note issue in 1844. On the other hand, Bank of England notes are legal tender except by the bank itself.

French Law.—In fundamental principles there is general agreement between the laws of all commercial nations regarding negotiable instruments. As Mr. Justice Story, the great American lawyer, says: "The law respecting negotiable instruments may be truly declared, in the language of Cicero, to be in a great measure not the law of a single country only, but of the whole commercial

world. *Non erit lex alia Romae, alia Athenis, alia nunc alia posthac, sed et apud omnes gentes et omni tempore, una eademque lex obtinebit*" (Swift v. Tyson, 16 Peters 1). But in matter of detail each nation has impressed its individuality on its own system. The English law has been summarized above. Perhaps its special characteristics may be best brought out by comparing it with the French code and noting some salient divergences. English law has been developed gradually by judicial decision founded on trade custom. French law was codified in the 17th century by the "ordonnance de 1673." The existing "Code de Commerce" amplifies but substantially adopts the provisions of the "Ordonnance." The growth of French law was thus arrested at an early period of its development. The result is instructive. A reference to Marius' treatise on bills of exchange, published about 1670, or Beawes' *Lex Mercatoria*, published about 1740, shows that the law, or rather the practice, as to bills of exchange was even then fairly well defined. Comparing the practice at that time with the law as it now stands, it will be seen that it has been modified in some important respects. For the most part, where English law differs from French law, the latter is in strict accordance with the rules laid down by Beawes. The fact is that, when Beawes wrote, the law or practice of both nations on this subject was nearly uniform. But English law has gone on growing while French law has stood still. A bill of exchange in its origin was an instrument by which a trade debt due in one place was transferred to another place. This theory French law rigidly keeps in view. In England bills have developed into a paper currency of perfect flexibility. In France a bill represents a trade transaction; in England it is merely an instrument of credit. English law affords full play to the system of accommodation paper; French law endeavours to stamp it out. A comparison of some of the main points of difference between English and French law will show how the two theories work. In England it is no longer necessary to express on a bill that value has been given for it, for the law raises a presumption to that effect. In France the nature of the consideration must be stated, and a false statement of value avoids the bill in the hands of all parties with notice. In England a bill may be drawn and payable in the same place. In France the place where a bill is drawn should be so far distant from the place where it is payable that there may be a possible rate of exchange between the two. This so-called rule of *distancia loci* is said to be disregarded now in practice, but the code is unaltered. As French lawyers put it, a bill of exchange necessarily presupposes a contract of exchange. In England since 1765 a bill may be drawn payable to bearer, though formerly it was otherwise. In France it must be payable to order; if it were not so it is clear that the rule requiring the consideration to be truly stated would be a nullity. In England a bill originally payable to order becomes payable to bearer when indorsed in blank. In France an indorsement in blank merely operates as a procuration. An indorsement, to operate as a negotiation, must be to order, and must state the consideration; in short, it must conform to the conditions of an original draft. In England, if a bill is dishonoured by non-acceptance, a right of action at once accrues to the holder. In France no cause of action arises unless the bill is again dishonoured at maturity; the holder in the meantime is only entitled to demand security from the drawer and indorsers. In England a sharp distinction is drawn between current and overdue bills. In France no such distinction is drawn. In England no protest is required in the case of the dishonour of an inland bill, notice of dishonour being sufficient. In France every dishonoured bill must be protested. Opinions may differ whether the English or the French system is better calculated to serve sound commerce and promote a healthy commercial morality. But an argument in favour of the English system may be derived from the fact that as the various Continental codes are from time to time revised and re-enacted, they tend to depart from the French model and to approximate to the English rule. The effect upon English law of its codification has yet to be proved. A common objection to codification in England is that it deprives the law of its elastic character. But when principles are once settled common law has very little elasticity. On the other hand no code

is final. Modern parliaments legislate very freely, and it is a much simpler task to alter statute law than to alter common law. Moreover, legislation is cheaper than litigation. One consequence of the codification of the English law relating to bills is clear again. Nearly all the British colonies have adopted the Act, and where countries are so closely connected as England and her colonies, it is an obvious advantage that their mercantile transactions should be governed by one and the same law expressed in the same words.

The following court decisions relating to bills of exchange and cheques may be singled out for special mention here. In *Jones v. Waring and Gillows* (1926) A. C. 670, the House of Lords definitely settled that the original payee of a bill or note is not a holder in due course as there has been no negotiation of the bill within the meaning (ss. 29-31). For example, if X is induced by the fraud of Y to draw a cheque in favour of Z, X is not in any way liable to Z.

A draft drawn by one branch bank on another is not a bill of exchange within the meaning of s. 60 of the Bills of Exchange Act 1882, but it is a draft or order within the meaning of s. 19 of the Stamp Act 1853, which protects bankers paying such drafts under a forged indorsement (*Capital & Counties Bank v. Gordon* [1903], A.C. 240). It is still uncertain whether this section protects a banker so paying in the case of a draft drawn abroad. A draft on a banker with a receipt annexed as a condition of payment is not a bill of exchange drawn on a banker payable on demand because it is not "an unconditional order to the banker to pay." But a cheque written on a blank sheet of paper, on the face of which the drawer wrote "to be retained" and promised to send one of his bankers' printed cheques in substitution, is an unconditional order to pay as regards the drawer's bankers, and the payee can sue thereon if it is dishonoured on presentation for payment (*Roberts v. Marsh* [1915] K.B. 42).

A foreign bill of exchange indorsed in France by an agent of the payee in the agent's own name without the words "per pro" or their equivalent but so indorsed by the payee's authority is a valid and sufficient indorsement and does entitle the payee under s. 72 of the Bills of Exchange Act to recover the amount thereof from the acceptors (*Koechlin & Cie v. Kestenbaum Bros.* [1927] K.B. 889).

Finally bankers' anxiety as to their liability where the amount of a cheque has been altered in fraud of a careless drawer has now been set at rest by the decision in *London Joint Stock Bank Ltd., v. Macmillan and Arthur* (1918). A.C. 777, where the House of Lords held, that the plaintiff firm had been guilty of a breach of the special duty arising from the relation of banker and customer to take care in the mode of drawing a cheque; that the alteration in the amount of the cheque was the direct result of that breach of duty; and that the bank were therefore entitled to debit the firm's account with the full amount of the cheque.

As Lord Shaw said in his judgment: In the case of a customer's cheque, admittedly genuine, no responsibility rests upon the banker for what has happened to the cheque before its presentation to the bank, but the responsibility for what has happened to it between the dates of signature and presentation rests upon the customer.

The ordinary text-books on the law of bills of exchange are constantly re-edited. See especially Byles, *Bills of Exchange*; Chalmers, *Bills of Exchange*; Nougier, *Lettres de change et des effets de commerce* (France); Thorburn, *Bills of Exchange Act 1882* (Scotland); Hodgins, *Bills of Exchange Act 1890* (Canada).

United States Practice.—The American law as laid down in the Uniform Negotiable Instruments Law, prepared in 1897 and by 1927 adopted without substantial change in all the States, is largely modelled on and harmonious with the British.

Some differences require noting: American national banks still can and do issue bank notes, though Federal Reserve notes and government notes representing actual deposited coin, called gold and silver certificates, have become much the more typical note currency of the country. There is no longer a stamp tax on notes or acceptances. Days of grace on bills of exchange have been abolished, except in a very few States, as to sight drafts. The

American cases are divided on whether a purchaser of overdue paper can secure better rights than his transferor had. They are divided also on whether the original payee of a bill, note or check can become a holder in due course, and on whether a drawer who negligently leaves spaces which facilitate raising the amount can hold his bank liable for the difference after the bank has paid in good faith. The other points on which specific cases are cited above are not of moment in American law. An Inland bill which does not require protest means a bill payable in the same State in which it is drawn. And the Negotiable Instruments Law contains no codified provisions as to what law governs transactions involving bills and notes which cross state boundaries, although the courts have ruled on most of the relevant points. The system of crossing checks is unknown in the United States; and a banker paying over a forged instrument is not protected in charging the drawer's account. He is, however, entitled to recover the payment from the person who thus received it on an invalid, though apparent, title. It may well be that the two systems are not particularly different in their practical effects in hindering forgery. Under the English the collecting banker, to be safe from ultimate liability, must and does collect only for a customer, *i.e.*, one whom he regularly deals with, and knows. Under the American the practical result of the collecting banker's absolute liability is somewhat the same: it is equally unsafe to collect for a stranger. So far, however, as the English check is crossed specially, or carries the notation "non-negotiable," or "account payee," it would seem to carry additional safeguards.

Divergences in Practice: But the bulk of the divergences in the two countries lie rather in men's practices than in the law. The form of banker's advance in America is not by prearranged overdraft, but by some such device as the banker taking the customer's note and crediting his account. And especially, it is the note, not the acceptance, which is in America the common instrument of credit. Nor can it be overlooked that credit instruments are much less used in America than in England in mercantile transactions—as contrasted with banking, or real estate mortgage, or open market borrowing transactions. The common American mercantile practice for a seller is to evidence credit by mere book entries, and to wait for his money, whereas in England it is common for the seller to take the buyer's acceptance at once on delivery of the goods, and to proceed to realize funds by discounting the acceptance with a banker or investor. This English practice prevails in American export trade; furthermore, under the Federal Reserve Act a very considerable volume of transactions has grown up in which the buyer's banker gives acceptances in the buyer's behalf, against commission and security. But the attempt at general introduction of the acceptance into domestic trade—the "trade acceptance" movement, seems to be making very slow headway.

Checks: On the other hand the check bulks even larger in the United States than in England. This involves no real disharmony with the foregoing. For whereas the true bill of exchange, payable thirty to ninety days after acceptance, is primarily a credit instrument, which can hardly flourish where men are content to leave debts in open account, the check—drawn on a bank, and payable on demand—is an instrument of payment, and useful in payment regardless of the credit system. The reliability of the check as an assurance of payment can be greatly increased by certification, *i.e.*, by the banker on whom the check is drawn stamping or writing across the check a form of words—such as "certified" or "good"—which by law makes the banker directly responsible for payment. Certification, which is very common in America, is therefore closely similar to acceptance of a time bill of exchange. But since the drawer's order on a check is to pay on demand, the banker who certifies has not in strictness honoured the order, and when the payee acquiesces in, or induces, the banker's act the drawer is discharged as in the case of a qualified acceptance. (N.I.L. s. 187, 188, 142.) After a check has been certified for the holder payment can no longer be stopped by the drawer, nor refused for insufficient funds; it is therefore necessary and proper for the banker, on certifying, to immediately charge the drawer's account to cover his own obligation. It must

be noted, however, that, if it is the drawer himself who has the check certified in order to procure an instrument which he can use as the full equivalent of cash, he retains some power to stop payment until the check passes into the hands of a holder in due course.

Investment Instruments: The American Negotiable Instruments Law undertakes, as the English act does not, to lay down the requirements to which "an instrument to be negotiable must conform" (s. 1). Chief among these requirements is that the instrument contain an unconditional promise or order to pay a sum certain in money. This language may be and often has been construed to deny negotiability to any document of any kind which fails to meet the requirements laid down, a situation which has given rise to some perplexities and conflicting decisions in regard to long-term investment instruments. Especially concerned are bonds—which have their promise to pay conditioned on various clauses of the underlying mortgage—and such more modern instruments as interim certificates, by which the maker engages, not to "pay a sum certain in money," but to deliver a described bond when issued. This ill-advised extension of a code drawn primarily with notes, bills of exchange and checks in mind has made current dealings in investment paper somewhat uncertain, despite the established practice on the exchanges of relying on a purchase bona fide and for value just as if the paper carried the full protection of negotiability. All that can yet be said with certainty is that in the absence of a specific statute such as is found in New York, or of amendment in the code, a purchaser of such paper cannot be sure of acquiring rights any better than those of his seller.

The American authorities are best collected in Brannan, *Negotiable Instruments Law* (4th ed. by Chafce, 1926); Paton, *Digest of Legal Opinions and Banking Law* (1926). (K. N. L.)

BILL OF EXCHANGE, IN PRACTICE. Stripped of its legal technicalities, a bill is an unconditional order in writing, signed by the person giving it (the drawer), requiring the person to whom it is addressed (the drawee) to pay on demand or at some fixed time a given sum of money to, or to the order of, a named person (the payee), or to bearer.

A cheque is a particular, though very common, form of bill. The bank is, and must be, the drawee, and it must be payable on demand, and without needing the acceptance of the bank. Otherwise, it has all the functions of a bill.

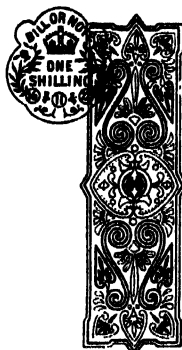

The Simplest Form of Bill.—Unlike a cheque, a bill can be, and usually is, drawn on a private person, and not a bank, and is also not usually payable "on sight" or "on demand," but at a definite date, such as three months "after sight." Take first a very simple British example:

Take the bill, bit by bit. It is for £100, no less and no more, and therefore has to have a shilling revenue stamp. It is drawn by W. Robinson, of Birmingham, on Henry Smith, London, and made payable to drawer. It is payable three months after sight, and has on it the mystic words "value received," which suggest that Mr. Smith has, in Mr. Robinson's opinion, received due value for the money which this bill is intended to extract from him.

The first step in the bill's life is for Mr. Robinson to get Mr. Smith to accept it. This is done by presenting it to Mr. Smith, who writes across it the words shown in the example, not only accepting it, but also "domiciling" it, that is, saying where the bill must be presented for payment—in this case at Mr. Smith's bankers. The date of acceptance is important, for it is from this that the three months run. In this instance, the bill would become payable on March 7, 1928, as allowance must be made for the three traditional and customary "days of grace." Henceforward Mr. Smith is called "the acceptor."

Mr. Robinson now gets the bill back, and he can do one of three things. He can keep it until "maturity," *i.e.*, March 7th, and then endorse it, take it round to Mr. Smith's bank, present it, and get his cash. Or he can endorse it in blank (*i.e.*, sign his name across the back, thereby making it payable to bearer) and hand it to his own bank, say Lloyds Bank, "for collection." Then his bank does the rest, and credits him with the £100, so soon as it

BILL OF EXCHANGE

	No. <i>123</i> Accepted <i>£100.0s.0d.</i> Payable at Westminster Bank, Ltd. Lombard Street. London, 11th January 1928	LONDON, 11th January 1928 At 90 days <i>after date pay to my Order</i> the sum of one hundred pounds sterling Value received. <i>William Robinson</i>	(1) A TYPICAL DRAFT ACCEPTANCE, PAYABLE 90 DAYS AFTER DATE OF DRAFT, FORMALLY ACCEPTED BY THE DRAVEE, WHO THEREBY AUTHORISES HIS BANK TO PAY THE DRAFT ON DUE DATE TO THE ORDER OF THE DRAWER. THE NATURE OF THE TRANSACTION FOR WHICH PAYMENT IS MADE IS NOT SPECIFIED
	To Henry Smith Birmingham		
	EXCHANGE FOR <i>£100.0s.0d.</i> London, 11th January 1928 At 90 days' sight <i>pay this First of Exchange second</i> <i>and third unpaid to the Order of Union Bank, London</i> the amount of one hundred pounds sterling against cargo 10 tons steel sheets Value per S.S. "President" to Bombay To Messrs. Smith, Jones & Company, Bombay	<i>which place to Account.</i> <i>William Robinson</i>	(2) A DRAFT IN RESPECT OF A SHIPMENT OF GOODS, THE EXACT NATURE OF WHICH IS SPECIFIED, PAYABLE 90 DAYS AFTER "SIGHT" BY THE DRAWERS IN BOMBAY. THE DRAFT IS IN TRIPPLICATE, ONE COPY BEING DESPATCHED WITH THE SHIPPING DOCUMENTS AND THE TWO REMAINING BEING SENT BY SEPARATE MAILS, THUS ENSURING THE SAFE ARRIVAL OF AT LEAST ONE COPY

USUAL FORM FOR 90 DAY DRAFTS (1) WITHOUT AND (2) WITH CONSIDERATION SPECIFIED

receives it. In both these cases, Mr. Smith has to wait for his money until March 7, so he may adopt the third alternative, and discount the bill, i.e., sell it at his bank.

In this case he endorses it "to the order of Lloyds Bank," and sells it to Lloyds Bank for what he can get. Naturally he will not get £100, for the bank will charge him a sum corresponding: (a) to the time they are out of their money, and (b) to the risk they are running of the bill not being met. Say first-class bills at that time are subject to a discount rate of 4%. The bank might add another 2%, to allow for the fact that Messrs. Smith and Robinson are not so sound or so wealthy as Messrs. Rothschild or Baring, making 6% in all. £6 os. od. per cent. per annum equals £1 10s. 7d. per cent. for the 93 days from Dec. 4 to March 7. So, for his bill for £100, the bank will only pay him £98 9s. 5d.

The bill is now the property of Lloyds Bank, and before presenting it, they must endorse it in their turn. Theoretically, they too could sell it before maturity, but British banks make a practice of never selling their own bills. Foreign banks, however, do sell bills out of their portfolio, and it is not uncommon for a bill, on maturity, to be found to have half-a-dozen endorsements on it, showing the people who have bought and sold it in the meantime.

Now to see the uses of a bill.

(1) From the drawer's standpoint, it enables him to get a definite dated promise to pay out of the drawee, and also to give the drawee the credit he needs and at the same time be able to get spot cash himself, if he wants it.

(2) From the drawee's or acceptor's standpoint, it enables him to get credit, even though the drawer wants spot cash.

(3) From the banker's standpoint, it provides him with an ideal means of employing his liquid funds. We have seen a bill can be transferred by endorsement, and so is as good as currency. In many ways, it is better than currency. It earns interest; it matures at a definite and early date; and the more endorsements it acquires, the safer it becomes.

The reason for this is that if the acceptor cannot pay, the "holder," i.e., the man actually presenting it, can come down on each endorser in turn and finally on the drawer. Everyone whose name is on the bill may find himself liable, and so the more names there are on it, the better the security.

This is the simple case of the inland bill, which, by 1928, was nearly as dead as the dodo.

Bills and Foreign Trade.—Foreign trade is naturally more complex. The currency question comes in; different countries have different laws, and the drawer and drawee may not be known to each other. To overcome these difficulties, commercial practice has evolved several devices.

The obvious problem arises from the fact that the exporter wants to be paid on shipping the goods, while the importer does not want to pay until he receives the goods. To bridge the interval, the 60 or 90 days' bill is the obvious medium, while, in the days of sailing ships and slow voyages, a six months' bill was often required.

Now, when a cargo arrives, the importer has to establish his title to it. He does that by presenting the set of documents, such as the invoice, the bill of lading, insurance policy, certificate of origin, etc., etc., which together authorize the ship's captain to hand over the goods. This the exporter knows, so that, if he is not sure of his man, he does not send him the documents direct, but stamps his bill (D.A.) and forwards the documents with the bill to his collecting agent, probably his bank. His bank sends all these papers to its correspondent in the importer's town, and he, knowing that (D.A.) means "documents against acceptance," makes the importer accept the bill, before handing over the documents. So the importer must accept the bill before he can get the goods.

The bill can be stamped D.P. Then the importer must pay the bill before the documents are handed over. Of course, he can pay all or part of the bill before maturity, and if so, he is allowed a rebate, as he has paid before the due date.

Above is an example of a D.A. bill. The drawer has arranged with his bank to discount it for him, and so, to save an endorsement, has drawn it to the order of his bank. The bank credits the drawee at once, endorses the bill, sends it with the documents to its correspondent for acceptance, and instructs its correspondent either to hold it until maturity, or to discount it.

To avoid the risk of loss in transmission, bills and documents are often prepared in triplicate, each set of papers being sent separately. This explains the term "First of Exchange."

The actual cargo to which the transaction relates is stated on the bill. This shows everyone concerned that it is a genuine transaction, and that, if things go wrong, the holder may be landed with a cargo of steel sheets to dispose of.

Bills to which documents are attached are called "documentary bills." When the documents are detached and handed to the importer, they become "clean bills."

Accepting Houses.—The next device described was evolved to meet the case of an importer who was not known to the exporter. Here he can arrange with some bank or "accepting house," of world-wide repute, to accept the bill for him. Thus Smith, Jones & Co., may be quite a sound concern, but not known in London, or to Mr. G. Brown. Their own bank, the Indian Chartered Bank, with offices in Bombay and London, or perhaps a big London accepting house, such as Lazards or Barings, may know all about Smith, Jones & Co., and be perfectly satisfied with them. So Smith, Jones pay their bank a small commission, say 1%, to accept or endorse the bill on their behalf. The bank may insist upon having the documents or allow them to go direct to Smith, Jones, but in any case, Mr. Brown is now able to draw a first-class bill, which he can discount at the finest or lowest rate.

Every bank carries in its balance sheet an item "acceptances, and endorsements on behalf of customers," which represents its engagements in this respect.

Banker's Credits.—This introduces the next device, namely that of banker's credits. This is a very technical question and can be dealt with only briefly. If an importer arranges for his bank to open a credit on his behalf, it means that the bank will allow the exporter to draw his bills on the bank instead of on the importer up to the limit and in accordance with the terms of the credit, and will accept such bills. Credits take many forms, some of which are sketched below.

Confirmed Banker's Credit.—This is the form of credit described above. Once granted, it cannot be revoked either by the importer or the bank.

Unconfirmed Banker's Credit.—This is less binding. The banker says only that he may accept the bills, and while, in general, he does so, he is not absolutely bound.

Documentary Credit.—Here the bank engages to advance the money on the bills, and the importer is left to accept them himself. The documents are retained by the bank as security, and the bill, though accepted by the importer, is paid direct by the bank.

Clean Credit.—Here there are no documents or other evidence of genuine business, so that bankers grant these only to people they are sure of. In brief, the banker promises the drawee to buy the bills from the drawer, while the drawee promises to accept them and pay them on maturity.

A credit may be opened in respect of a definite shipment, and expires when the transaction is completed. On the other hand, many credits are continuous. When the first bill is duly paid, the bank will agree to accept a second, and so on, provided that the total of bills outstanding at any one time does not exceed the limit of the credit. Such credits are called *Revolving Credits*. For further information, see W. F. Spalding, *Bankers' Credits and Foreign Exchange and Foreign Bills* (Sir Isaac Pitman and Sons).

The London Money Market.—Next it is necessary to consider bills drawn on London, and the London money market. A bill is not necessarily drawn on the importer, or even on a bank in the importer's or exporter's country. The two may agree that the importer shall have a credit opened by a London bank, on which the exporter can draw. The importer either does this direct, or through his own bank. This is a common practice, because London is the chief bill market of the world, and so there is a ready demand for bills. Hence the exporter can be sure of selling his bill at the best rate.

Demand for bills in London comes from many sources. All the London banks, and many foreign banks, are seeking for bills maturing at various specified dates, while, in 1927, foreign Central banks were buying up bills as backing for their note-issues and deposits. In many ways, bills are ideal backing for currency. They have only a definite life, and their decease automatically contracts

the currency issue, as the issuing bank can have the bill paid in its own notes, which it can then retire. The chief operator in the London money market is the bill-broker. He buys bills from the foreign banks and other sources, sorts them into maturities, and sells to the British banks bills maturing at such dates as they require. He finances his stock of bills by short loans from the London banks (see MONEY MARKET) and the London market deals in clean bills only.

So far, trade bills have been considered. Other important bills are: (1) Finance bills, drawn by one banker on another to effect a temporary transfer of funds. Finance bills are a means of anticipating and making provision for a coming demand for money in a particular quarter, such as the demand for money to pay for crops. (2) Treasury bills, drawn on H. M. Treasury and usually maturing in three months. These are sold each week by tender, and enable the Treasury to borrow money for a period of three months. Every week, so many bills mature, and so many fresh ones are sold. (3) Corporation bills, drawn on the big British provincial cities, to enable them to borrow money for the term of the bill.

Some confusion often arises from the rate of discount of a bill. The price of the bill is the difference between the face value of the bill and the discount thereon. Hence the important rule that dear money means high discount rates and cheap bills. "Market rate" is the discount rate on three months' bank bills, that is, bills accepted or endorsed by a London bank or accepting house. It is the finest (or lowest) rate current in London, and so three months' bank bills command the best price. A six months' bill will be cheaper, because bankers are loth to tie up their money so long. A bill without a bank name will be cheaper, because the security is less. At the bottom of the scale come bills drawn by one impecunious person upon another, with the object of discounting the bill somewhere, and the drawer and acceptor sharing the proceeds. Often each will draw simultaneously upon the other, and discount the two bills in different places. This is the theory of the game. In practice, bankers and the market term such bills "pig upon pork," and refuse to look at them. (N. E. C.)

BILL OF HEALTH, a document given to the master of a ship by the consul or other proper authority of the port from which he clears, describing the sanitary state of the place. A bill of health may be either "clean," "suspected," "touched" or "foul." A "clean" bill imports that at the time the ship sailed no disease of an infectious or contagious kind is known to exist, a "suspected" or "touched" bill, that no such disease has as yet appeared, but that there is reason to fear it, a "foul" bill, that such a disease actually exists at the time of the ship's departure. Bills of health are necessary where the destination of the ship is a country whose laws require the production of such a bill before the ship is allowed into port, and where, in default of such production, the ship is subjected to quarantine.

BILL OF MORTALITY. In England this was a weekly return issued under the supervision of the company of parish clerks showing the number of deaths in a parish. During the Tudor period England suffered much from plague, and various precautionary measures became necessary. Quarantine or isolation was the most important, but to carry it out successfully it was necessary to have early warning of the existence of plague in each parish or house. For this purpose searchers—usually women—were appointed, who reported to the clerk the cause of each death in the parish. He, in turn, sent a report to the parish clerks' hall, from whence was issued weekly a return of all the deaths from plague and other causes in the various parishes, as well as a list of those parishes which were free from plague. Bills of mortality are usually said to date from 1538, when parish registers were established by Cromwell (Lord Essex), but there is extant a bill which dates from Aug. 1535, and one which is possibly even earlier than this. It is certain that they first began to be compiled in a recognized manner in Dec. 1603, and they were continued regularly from that date down to 1842, when under the Births and Deaths Registration act, 1836, they were superseded by the registrar-general's returns. It was not till 1728, when the ages of the dead were first introduced, that bills of mortality

acquired any considerable statistical value. It was on the data thus furnished that the science of life insurance was founded.

BILL OF RIGHTS, an important statute in English constitutional history enacted in Dec. 1689. Its provisions were based upon the Declaration of Right and delivered by the lords and commons to the Prince and Princess of Orange, afterwards William III and Mary. The act (the full name of which is "An Act declaring the Rights and Liberties of the Subject, and settling the Succession of the Crown"), after reciting the unconstitutional proceedings of James II, the abdication of that King, the consequent vacancy of the Crown, and the summons of the convention parliament, declared, on the part of the lords and commons, "for the vindicating and asserting their ancient rights and liberties":—

"(1) That the pretended power of suspending of laws or the execution of laws by regal authority without consent of Parliament is illegal. (2) That the pretended power of dispensing with laws or the execution of laws by regal authority, as it hath been assumed and exercised of late, is illegal. (3) That the commission for erecting the late court of commissioners for ecclesiastical causes, and all other commissions and courts of like nature, are illegal and pernicious. (4) That levying money for or to the use of the Crown, by pretence of prerogative, without grant of Parliament, for longer time or in other manner than the same is or shall be granted, is illegal. (5) That it is the right of the subjects to petition the King, and all commitments and prosecutions for such petitioning are illegal. (6) That the raising or keeping a standing army within the kingdom in time of peace, unless it be with consent of Parliament, is against law. (7) That the subjects which are Protestants may have arms for their defence suitable to their conditions, and as allowed by law. (8) That elections of members of Parliament ought to be free. (9) That the freedom of speech, and debates or proceedings in Parliament, ought not to be impeached or questioned in any court or place out of Parliament. (10) That excessive bail ought not to be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted. (11) That jurors ought to be duly empanelled and returned, and jurors which pass upon men in trials for high treason ought to be free-holders. (12) That all grants and promises of fines and forfeitures of particular persons before conviction are illegal and void. (13) And that for redress of all grievances, and for the amending, strengthening, and preserving of the laws, Parliament ought to be held frequently. And they do claim, demand, and insist upon all and singular the premises, as their undoubted rights and liberties."

The further provisions of the act were concerned with the settlement of the Crown upon the Prince and Princess of Orange, with the exception of Section 12, which negated the right of dispensation by *non obstante*¹ to or of any statute or any part thereof, unless a dispensation be allowed in the statute itself or by bill or bills to be passed during the then session of Parliament.

The Bill of Rights introduced no new principle into the English constitution; it was merely a declaration of the law as it stood. In the United States, the main provisions of the Bill of Rights, so far as they are applicable, have been adopted both in the constitution of the United States and in the state constitutions.

BILL OF SALE, a legal document assigning personal chattels, and also used in connection with the transference of property in ships. The term has come to be applied to mortgages as well as to sales, and the expression "bill of sale" may now be understood to signify generally a document evidencing a sale or mortgage of personal chattels, unaccompanied by an actual transfer of possession to the purchaser or mortgagee.

The first English legislation on the subject was the Bills of Sale Act 1854. This provided that all bills of sale, as defined in the act, should be void against execution creditors unless registered. It was amended by the Bills of Sale Act 1866. These acts were repealed and a new act passed, the Bills of Sale Act 1878, which in the main followed the lines of the Act of 1854. The object of this legislation was to protect persons lending on bills

¹*Non obstante* (notwithstanding) means a licence from the crown to do that which could not be lawfully done without it.

of sale. In 1882 the Bills of Sale Act (1878) Amendment Act was passed to protect persons borrowing on bills of sale (*cf. Manchester, etc. Ry. Co. v. N.C. Wagon Co.*, 1888, 13 App. Cas. 554). This point is worth remembering, because the 1882 Act is the beginning of the tendency to protect impecunious borrowers who have no security to give for a loan save a charge on their household goods, or no security at all, which has culminated in the Money Lenders Acts of 1900 and 1926. The Act of 1882 has since been amended by the Bills of Sale Acts of 1890 and 1891 which effected further small amendments by excluding from the operation of the principal acts instruments hypothecating, charging or declaring trusts on imported goods, during the interval between their unloading from a ship and their deposit in a warehouse, or re-shipping.

Under the Acts of 1878 and 1882 bills of sale are of two kinds, i.e., *absolute bills of sale* (where chattels are sold absolutely to a purchaser), and *conditional bills of sale* (where the bill is given by way of security for the payment of money). The Bills of Sale Act 1878 applies to both kinds and is the only act applying to *absolute bills*. Bills of sale given in security for the payment of money on or after Nov. 1, 1882, are chiefly governed by the Act of 1882, which, however, does not apply to *absolute bills*. Section 4 of the Act of 1878 defines a bill of sale as (1) including bills of sale, assignments, transfers, declarations of trust without transfer, inventories of goods with receipt thereto attached, or receipts for purchase moneys of goods and other assurances of personal chattels; the term assurance has been best explained as a document "on which the title of the transferee of the goods depends, either as the actual transfer of the property, or an agreement to transfer," *Marsden v. Meadows*, 1881, 7 Q.B.D. 80; (2) powers of attorney, authorities or licences to take possession of personal chattels as security for any debt; these words would not include a power of distress for rent in an ordinary lease or *bona fide* hiring or hire purchase agreements; (3) any agreement, whether intended or not to be followed by the execution of any other instrument, by which a right in equity to any personal chattels, or to any charge or security thereon, shall be conferred; (4) any mode of disposition of trade machinery and attainments and other instruments giving powers of distress to secure a debt or advance. On the other hand, certain assurances and instruments are expressly exempt by statute from the definition: marriage settlements, assignments of ships, assignments for the benefit of creditors, bills of lading and dock warrants, and by the Act of 1882, debentures and debenture stock of a company. The expression "personal chattels" is defined as goods, furniture and other articles capable of complete transfer by delivery, and (when separately assigned or charged) fixtures and growing crops.

The law as to *absolute bills* being for the protection of the lender is concerned with conditions to secure that the borrowers shall not be able to repudiate them. Accordingly provisions are made that the bill containing all the essentials of the transaction verified by affidavit shall be attested by a solicitor who must testify that he, before its execution, explained to the grantor its effect; and shall be filed with the registrar within seven clear days of its execution. Failure to observe these requirements invalidates the bill only as against the execution creditors and trustee in bankruptcy of the grantor, it remains good as between the grantor himself and the grantee.

Bills of sale given by way of a security for a loan or a money debt (*conditional bills*) must be drafted in accordance with a form annexed to the act. The contents of this form are practically the same as those to be set out in an *absolute bill of sale* with the addition of a provision setting out that the chattels assigned by it shall not be liable to seizure or to be taken possession of by the grantee for any cause other than those specified in s. 7 of the Bills of Sale Act (1878) Amendment Act 1882. If this form is substantially departed from, a conditional bill, unlike an *absolute bill*, is void not merely as against the grantor's creditors and trustee in bankruptcy but also as between grantor and grantee.

The bill of sale must have annexed to it an inventory of the chattels comprised in it, and is void, except as against the grantor,

in respect of any personal chattels not specifically described. It must be duly attested by one or more credible witnesses (not necessarily by a solicitor, as in the case of absolute bills). Every witness must sign his name and add his address and description. It must be duly registered within seven clear days after the execution thereof, or if it is executed in any place out of England then within seven clear days after the time at which it would in the ordinary course of post arrive in England if posted immediately after the execution. It must truly set forth the consideration. The grantor must be the true owner of the goods described in the schedule; as to any personal chattels of which he is not the true owner, the bill is void, except as against the grantor. Every bill of sale made or given in consideration of any sum under £30 is void.

The causes which will render the chattels assigned by the bill liable to be seized or taken possession of are as follows: (1) If the grantor makes default in payment of the debt or in the performance of any covenant or agreement contained in the bill and necessary for maintaining the security; (2) if the grantor becomes a bankrupt or suffers the goods to be distrained for rent, rates or taxes; (3) if the grantor fraudulently removes the goods from the premises; (4) if the grantor does not, without reasonable excuse, upon demand in writing by the grantee, produce to him his last receipts for rent, rates or taxes; (5) if execution is levied against the goods of the grantor under any judgment. By s. 13 personal chattels seized or taken possession of under a bill must not be removed or sold until after the expiration of five clear days from the date of seizure, and if the goods have been wrongly seized, the grantor may within the five days apply to the high court or a judge in chambers for an order to restrain the grantee from removing or selling the goods. The Bills of Sale Acts 1878 and 1882 do not apply to Scotland or Ireland. According to Scots law no security or charge can be created over movable property without delivery of possession. The Irish statutes corresponding to the English Acts are the Bills of Sale (Ireland) Act 1879 and the Amendment Act 1883.

The stamp duties payable on an absolute bill of sale are 2s. 6d. on every £25 secured up to £300; over £300, 5s. on every £50. On bills of sale by way of security, 1s. 3d. for every £50 up to £300 secured; over £300, 2s. 6d. for every £100. The fees payable on filing a bill of sale are 5s. where the consideration (including further advances) does not exceed £100; above £100 and not exceeding £200, 10s.; above £200, £1.

The various trade protection papers always publish the registration of a bill of sale, and the usual effect is, therefore, to destroy the credit of any person giving one (T. A. 1; J. A. 57).

BILL OF SIGHT, a document furnished to the customs by an importer of goods in Great Britain who, being unable for want of full information to make a perfect entry of goods consigned to him, describes them to the best of his knowledge and information. The goods may then be provisionally landed, but perfect entry must be made within three days by endorsing on the bill of sight the necessary particulars. In default of perfect entry within three days, the goods are taken to the king's warehouse, and if perfect entry is not made within one month and all duties and charges paid, they are sold for payment thereof. A bill of sight should be carefully distinguished from a "sight bill," which is a bill of exchange payable at sight (see **BILL OF EXCHANGE**).

BILL OF STORE, a licence granted by the custom house permitting the re-importation of British goods into Great Britain. All British goods re-imported into Great Britain are entered as foreign, unless re-imported within ten years after their exportation and unless the property in the goods continues and remains in the person by whom they were exported. But in such case they may be entered as British goods, by bill of store, with the exception of corn, grain, meal, flour and hops.

BILL OF VICTUALLING, in its original meaning a list of all stores for shipment, but now an order from an export officer of the customs for the shipment from a bonded warehouse or for drawback of such stores as may be required and allowed with reference to the number of the crew and passengers on board a ship proceeding on an overseas voyage. It is made out by the

master and countersigned by the collector of customs. Its object is to prevent frauds on the revenue. No such stores are supplied for the use of any ship nor any articles taken on board deemed to be stores unless they are borne upon the victualling bill, and any such stores relanded at any place in the United Kingdom without the sanction of the proper officers of the customs will be forfeited and the master and owner will each be liable to a penalty of treble the value of the stores or £100. A victualling bill serves as a certificate of clearance when there is nothing but stores on board the ship.

BILL POSTING: see **ADVERTISING**.

BILLROTH, ALBERT CHRISTIAN THEODOR (1829-1894), Viennese surgeon, was born on April 26, 1829, at Bergen, on the island of Rügen, his family being of Swedish origin. He studied at the universities of Greifswald, Göttingen and Berlin, and, after taking his doctor's degree at the last in 1852, started on a tour of the principal medical schools of Europe. On his return to Berlin he acted as assistant to B. R. K. Langenbeck (1853-60), and then accepted the professorship of surgery at Zürich. In 1867 he was invited to fill the same position at Vienna, and in that city the remainder of his professional life was spent. In 1887 he received a distinction which has seldom been bestowed on members of his profession—a seat in the Austrian *Herrnhaus*. He died at Abbazia, on the Adriatic, on Feb. 6, 1894. Billroth was one of the most distinguished surgeons of his day. His boldness as an operator gained for him the appellation of "surgeon of great initiatives." He was especially interested in military surgery, and during the Franco-German War volunteered to serve in the hospitals of Mannheim and Weissenburg. He improved the arrangements for the transport and treatment of the wounded in war, and in a famous speech on the war budget in 1891 he urged the necessity for an improved ambulance system in modern warfare. His *Allgemeine chirurgische Pathologie und Therapie* (1863) ran through many editions, and was translated into many languages. He was a good musician, and an intimate friend and admirer of Brahms, many of whose compositions were privately performed at his house before they were published. His work on the physiology of music (*Wer ist musikalisch?*) was published after his death. His *Briefe*, first published in 1896, reached their 9th ed. in 1922.

BILMA or **KAWAR**, a Saharan oasis, 60 m. by 10. The inhabitants are Tibbu and Kanuri. The name Bilma belongs strictly to the south part near the chief settlement, Bilma or Garu. This place is 800 m. S. of the town of Tripoli and about 350 N. of the north-west corner of Lake Chad. The water of a number of lakes on evaporation yields large quantities of fine salt, the object of an extensive trade with Central Africa. North of Bilma is the town of Dirki, said to date from the 11th century. Near Bilma is a small oasis, kept green by spring water, but to the south marked desert conditions prevail. By the Anglo-French Declaration of 1899 Bilma was included in the French sphere of influence in West Africa. Turkey claimed the oasis and garrisoned Bilma in 1902. In 1906, however, a French force occupied the town without opposition. In 1907 the district was created a circle of the French Territory of the Niger (see **SAHARA**).

BILNEY, THOMAS (c. 1495-1531), English martyr, was born at or near Norwich. He was educated at Trinity Hall, Cambridge, graduating LL.B. and taking holy orders in 1519. Among his friends were Matthew Parker, the future archbishop of Canterbury, and Hugh Latimer. Latimer, previously a strenuous conservative, was completely won over, and a warm friendship sprang up between him and Bilney. "By his confession," said Latimer, "I learned more than in 20 years before." In 1525 Bilney obtained a licence to preach throughout the diocese of Ely. He denounced saint and relic worship, together with pilgrimages to Walsingham and Canterbury, and refused to accept the mediation of the saints. The diocesan authorities raised no objection, for, despite his reforming views in these directions, he was to the last perfectly orthodox on the power of the pope, the sacrifice of the mass, the doctrine of transubstantiation, and the authority of the church. But Wolsey summoned Bilney before him in 1526. On his taking an oath that he did not hold and would not disseminate the doctrines of Luther, Bilney was dismissed. But in the

following year he was arrested and convicted of heresy, sentence being deferred while efforts were made to induce him to recant, which eventually he did. After a year in the Tower, he was released in 1529, and went back to Cambridge. Here he was overcome with remorse for his apostasy, and preached openly in the fields, finally arriving in Norwich, where the bishop, Richard Nix, caused him to be arrested. He was burned as a relapsed heretic in London on Aug. 9 1531. A parliamentary enquiry into this case was threatened because it was alleged that Bilney's execution had been obtained by the ecclesiastics without the proper authorization by the State. In 1534 Bishop Nix was condemned on this charge to the confiscation of his property. The significance of Bilney's execution lies in the fact that on essential points he was an orthodox Roman Catholic.

BILOXI, a city of Harrison county, Mississippi, U.S.A., about half-way between Mobile and New Orleans, on a narrow peninsula extending into Mississippi sound, a part of the Gulf of Mexico. It is on the old Spanish trail and the Louisville and Nashville railway, and is connected by a bus line with the Illinois Central system at Gulfport. The population in 1920 was 10,937, of which 1,615 were negroes, and was estimated at over 16,000 in 1927.

Biloxi is both a summer and winter resort with more than the usual sea-side and country sports. Its vegetation, growing down to the water's edge, includes gigantic old live-oaks, dripping with Spanish moss, long leaf pines, magnolias, oleanders, camphor trees, and palms. The dominating industry is the catching, packing, and shipping of sea-food. The fleet of fishing smacks and other small craft numbers about 800. In a normal year, the shipments include more than 175,000 gal. of raw oysters packed in ice, 10,000,000 cans of oysters, and 8,000,000 cans of shrimps, besides fish, crabs, and turtles in large quantities.

Biloxi has been under five national flags (France, Spain, England, the Confederacy, and the United States) and two state flags. In 1699, Pierre le Moyne d'Iberville (1661-1706) built Fort Maurepas across the bay from the present city, and the settlement there was the first capital of the French territory. It took its name, meaning "the first people" from the tribe of Sioux found there. In 1712 a settlement was made on the present site, and this became the French capital from 1719 to 1722. An old house with walls of moss and clay is believed to date from this period and to be the oldest building in the Mississippi valley. In the war of 1812 the British fleet anchored off Ship island, preparatory to its attack on New Orleans, and during the Civil War Fort Massachusetts (now abandoned) on this island was an important base of Federal operations. On West Beach is Beauvoir, the home of Jefferson Davis, now appropriately occupied by the Mississippi Confederate soldiers' home. Biloxi was incorporated as a village in 1872, as a city in 1896.

BILSTON, urban district, Staffordshire, England, 2½ m. S E. of Wolverhampton, in the Black Country. Pop. (1921) 27,550. It is served by the G.W. and L.M.S. railways. In the vicinity are very productive mines of coal and ironstone, sand of fine quality for casting, and grinding-stones for cutlers. Bilston contains numerous furnaces, forges, rolling and slitting mills for the preparation of iron, and a great variety of factories for japanned and heavy iron goods. The town is ancient, appearing in Domesday.

BIMETALLISM. The very general employment of both gold and silver for currency purposes (see *MONEY*) has given rise to serious practical difficulties which have in turn led to keen theoretical discussion as to the proper remedies to be employed. Though every arrangement under which two metals form the money of a region may be described as "bimetallism," the term—as often happens in economics—has received a specialized meaning. It denotes a system under which the two metals are freely received by the mint and are equally available as legal tender. The last clause implies the establishment of a definite ratio in value between the two metals (e.g., 1 oz. of gold = 15½ oz. of silver) so that the title "rated bimetallism" may be given to it, in contradis-

inction to the "unrated bimetallism" which exists wherever two metals circulate together, but have their relative values determined, not by law, but by "the higgling of the market." Further, the inventor of the term—H. Cernuschi in 1860—regarded it as properly applicable to an international arrangement by which a number of states agree to adopt the same ratio, rather than to the use of the two metals by a single country, which may be described as national bimetallism. International bimetallism is at all events the form which has attracted attention in recent times, and it is certainly the most important.

Regarded from the historical point of view it appears that the failure of separate countries to maintain the two metals in circulation was the cause which produced the idea of bimetallism as an international system. We find first the upholders of a national double standard, as in France and the United States, and these are followed by the advocates of bimetallism set up by a combination of countries. The theoretical considerations which underlie the controversy between the supporters and the opponents of bimetallism find their appropriate place in the article *MONEY*, (q.v.) as does also the earlier history of the double standard. The circumstances that have led to the prominence of the bimetallic question and the principal events that have marked the course of the movement form the subject of this article.

Double and Single Standards.—In the earlier years of the 19th century, when the monetary disturbances that resulted from the Revolutionary wars had ceased, we find France (1803) and the United States (1792) with the double standard legally established. England, on the other hand, had in 1816 accepted by law the gold standard, which had come into use in the 18th century. Silver formed the currency of the other European countries. The great discoveries of gold in California (1848) and Australia (1851) brought about the displacement of silver by gold in France, and the continuance of gold as the principal currency metal in the United States, where by the law of 1834 it had been somewhat overrated (1.16), as compared with the ratio adopted in France (1:15½), and had therefore expelled most of the silver previously in circulation. Between 1848 and 1860 over £100,000,000 of gold was coined in France, while an equivalent amount of silver was exported, principally to the East.

At this time the weight of economic and official opinion was very decidedly in favour of the single gold standard as the best system. In 1865 the Latin Union was established, in which the French currency system was adopted and was followed by the international conference of 1867 in Paris (see *MONETARY CONFERENCES*), when gold was unanimously accepted as the standard for the proposed international system to be produced by co-ordinating the various currencies with that of the Latin Union.

A series of political and economic events speedily changed this situation. The Franco-German War (1870-71) deposed France from her leading position, and led to the establishment of a German gold currency with a different unit from the franc, accompanied by the demonetization of the silver currencies previously in use in the German states. The United States, where an inconvertible paper currency had been introduced during the Civil War, formally established the gold dollar as the standard coin (1873) and arranged for a return to specie payments (1878). At this time, too, the great production of gold which had marked the period 1850-70 diminished, while very productive silver mines were discovered in the Pacific states of America. As a result of these combined influences the gold price of silver, which had risen a little during the height of the gold discoveries, began to fall rapidly, and the reverse process to that by which France had in the '50s acquired a gold currency came into operation. Silver, in accordance with *Gresham's Law*, was imported and offered for coinage.

The Limping Standard.—To obviate this the policy of limiting the coinage of silver (the *Limping Standard*) was adopted by the Latin Union. A further fall in the gold price of silver naturally resulted, and this made the position of Eastern trade and the finances of the Indian government insecure. American silver producers, and the German government, as holders of a large mass of demonetized silver, were also sufferers by the deprecia-

tion. The effect on public and official opinion was shown by the English parliamentary committee on the depreciation of silver (1876), the American silver commission of the same year, and the appearance of many works on the subject, most of them advocating the double standard. On the initiative of the United States an international monetary conference met in Paris in 1878, but though the necessity of keeping a place for silver in the money of the world was recognized, the proposal to adopt the double standard for general use was rejected by the European states. By the Bland-Allison Act (Feb. 1878) the United States had provided for the coinage of a certain amount of silver per month as a mode of keeping up the price of the metal, which notwithstanding fell to 48 pence per oz. in 1879. The prolonged depression of trade in America and Germany was attributed to the scarcity of money, due to what was described as "the outlawry of silver." By the joint action of France and the United States a fresh monetary conference was held in Paris in 1881, where the advocates of bimetalism were very strongly represented. After prolonged discussion no conclusion was reached, in consequence of the refusal of England and Germany to abandon the gold standard. Though an adjournment to the following year was resolved on, the conference did not reassemble, and the bimetallic movement took the form of agitation, carried on in each country.

The English inquiry into the depression of trade (1885-86) drew from the commission a recommendation for a fresh commission to investigate the relation of gold and silver. This latter body, appointed in 1886, obtained a large amount of important evidence, and in 1888 closed its work by a report in which the views of the two sections of the commission were separately presented. Six members supported the existing gold standard and six were in favour of the bimetallic system.

Sherman Act, 1890.—This inconclusive result was soon followed in the United States by the Sherman Act (1890), providing for a larger monthly coinage of silver. A temporary rise in the price of the metal was followed by a further fall, making the situation still more critical. A new monetary conference was summoned by the United States and met in Brussels in Nov. 1892. To modify opposition the "desirability of increasing the use of silver" was the resolution proposed; the actual method being left open. This conference also proved abortive and adjourned to 1893, but like that of 1881 did not meet again.

International action having failed to secure any system of bimetalism, the United States and India sought to relieve their position by local legislation. The former repealed the Sherman Act, and the latter closed its mints to the free coinage of silver (1893). As these measures were opposed to bimetalism in that they restricted the use of silver, and were followed by a lower price for that metal than had ever been known, the agitation in the United States and Europe continued. In America it took the form of advocating the free coinage of silver by the United States without waiting for other countries; and in this shape made the principal issue at the presidential elections of 1896 and 1900, in each of which it was emphatically rejected.

The Last Attempt.—A further attempt at securing international bimetalism was made by Senator Wolcott's commission in 1897. The American envoys, in concert with the French government, proposed to England (1) the reopening of the Indian mints, and (2) the annual purchase by England of £10,000,000 of silver. The French minister claimed further concessions which were regarded as inadmissible by the English government; but the fate of the mission was settled by the refusal of the Indian government to reopen its mints.

After the American election of 1900, bimetalism as a popular cause disappeared from view. The silver issue was withdrawn from the democratic platform in 1904, and the bimetallic movement died out in England.

Amongst the causes of this collapse the most important were: (1) the adoption of the *gold standard* by so many countries, (2) the great increase in the output of gold which removed all that dread of a "gold famine" which served as a popular argument with bimetalists, (3) the knowledge that experience had brought of the difficulties surrounding any attempt to establish a common

ratio where the interests of different countries are so opposed; and (4) the great expansion of trade and industry, concomitantly with the wider adoption of the gold standard. Therefore, to quote the words of perhaps the ablest advocate of bimetalism, "The outcome of the prolonged controversy . . . appears to be that the commercial world will carry on its business principally and more and more on a gold basis, and that particular countries will endeavour in different ways to adjust their actual medium . . . to the gold standard" (Nicholson, *Money and Monetary Problems*, 6th ed.).

Perhaps the principal service rendered by the many able minds engaged in the movement will prove to be the fuller development of the more difficult parts of monetary theory and the additional light thrown on the course of monetary history.

A proposal, sometimes confounded with bimetalism, is that for a standard composed of both gold and silver, which is better described as the *Joint-standard* or as *Symmetallism*.

Leonard Darwin's *Bimetalism* aims at a judicial summary. See also MONEY, MONETARY CONFERENCES. (C. F. B.)

BIMLIPATAM, a town of British India, in the Vizagapatam district of Madras, on the sea-coast 18m. north-east of Vizagapatam, and 16m. from a station on the Bengal-Nagpur railway. Pop. (1921) 7,495. It was formerly a Dutch factory and is now the principal port of the district. The anchorage is an open roadstead protected to some extent by headlands with a lighthouse at Santapalli. Trade is coastal, the foreign trade having declined since the World War. There is regular coolie traffic with Rangoon. The principal exports are oil-seeds and jute. Ships lie a mile offshore.

BIÑAN, a municipality (with administration centre and 16 barrios or districts), of the province of Laguna, Luzon, Philippine Islands, on the west shore of Laguna de Bay, about 20m. S.S.E. of Manila. Pop. (1918), 10,692, of whom 5,183 were males and none white. The fertile region roundabout produces corn, abaca, tobacco, rice and many tropical fruits, some of which find a ready market in Manila. It had 69 manufacturing establishments in 1918 with output valued at 291,000 pesos besides 164 household industry establishments with output valued at 79,900 pesos; and ten schools, of which six were public. The language is Tagalog.

BINARY SYSTEM, in astronomy, a system composed of two stars revolving around each other under the influence of their mutual attraction. It is probable that at least one-third of the stars are binary systems. In some cases (visual binaries) a telescope will show the two components separated. In others (spectroscopic binaries) the duplicity is detected by observing the changing motion in the line of sight of one or both components. (See STAR.)

BINCHOIS, GILLES, an early 15th-century Flemish musical composer, evidently named after his birthplace, Binche, near Mons. He was esteemed by contemporary and later theorists as second only to Dunstable and Dufay. A selection of his works is printed in *Denkmäler der Tonkunst in Oesterreich* (vols. vii. and xi). Binchois died at Lille in 1460.

BINET, ALFRED (1857-1911). French experimental psychologist, was born in Nice, on July 8, 1857. At an early age he went to Paris and entered the Lycée Saint-Louis from which he graduated in 1878. In 1890 he took a degree in natural science at the Sorbonne and received his D. Sc. in 1894. The laboratory of psychology and physiology was created at the Sorbonne in 1889 and three years later Binet was invited to join its staff as assistant to M. Beaunis. Upon the retirement of Beaunis in 1894, Binet became director. With Beaunis and Ribot he began in 1895 to publish the journal *L'Année psychologique*. This journal, under Binet's leadership, expressed the French movement in psychol-

ogy. His inclination for varied psychological problems soon drew him towards the study of hypnotism and while working in this field he published with Fere, *Le magnétisme animal* and *Les altérations de la personnalité*. His name, however, is most generally connected with his researches on human intelligence and more specifically with his scales and tests to measure intelligence. These tests, first published in connection with his *Étude Expérimentale de l'intelligence* (1905-08), have had wide usage. He made extensive investigations in other psychological fields and the list of his publications is large. Among his works are: *Introduction à la psychologie expérimentale*, with Philippe, Courtier and V. Henri (1894); *La fatigue intellectuelle*, with V. Henri (1898); *La suggestibilité* (1900); *L'âme et le corps* (1905); *Les enfants anormaux*, with Simon (1907). He died in Paris, on Oct. 18, 1911.

See R. Martin, *Alfred Binet* (Paris, 1925).

BINGEN (ancient VINCUM or BINGIUM), town, Germany, in the province of Rhein-Hessen, in the Folk-State of Hesse Hesse-Darmstadt, on the left bank of the Rhine, 15m. N.W. of Mainz. Pop. (1925) 9,146. The Romans erected a castellum here, and there remains a bridge of Roman origin over the Nahe. Bingen was a free town of the empire. A short way down the Rhine is the Bingerloch, a whirlpool whose fame helped the growth of the town. Many legends have gathered about this portion of the Rhine valley, and its romantic associations and beautiful scenery have made Bingen a famous tourist centre. There is also an important pilgrimage in August. The parish church dates from the 15th century, but has an 11th century crypt. Commerce is in wine and spirits, and considerable transit trade is done by river.

BINGHAM, JOSEPH (1668-1723), English scholar and divine, was born at Wakefield in Yorkshire in Sept. 1668. Educated at University college, Oxford, he was made fellow in 1689 and tutor in 1691. A sermon preached by him from the university pulpit (St. Mary's), on the terms "Person" and "Substance" in the Fathers, brought upon him an unjust accusation of heresy. He was compelled to give up his fellowship; but he was immediately presented by Dr. John Radcliffe to the rectory of Head-bournworthy (1695). There he began his great work entitled *Origines Ecclesiasticae*: the first volume appeared in 1708 and the tenth and last in 1722. Bingham was collated in 1712 to the rectory of Havant. He died on Aug. 17, 1723.

BINGHAMTON, a city of New York, U.S.A., picturesquely situated on the Susquehanna river, at the mouth of the Chenango, 125m. S.W. of Albany, near the Pennsylvania border; the county-seat of Broome county. It is on the Appalachian scenic highway, and is served by the Erie, the Delaware and Hudson, and the Lackawanna railways. A commercial air-port is projected. The area is 0.48sq.m. The population was 17,317 in 1880; 39,647 in 1900; 66,800 in 1920, of which 10,368 were foreign-born white; and was estimated at 73,900 in 1927.

Dairy farming is the agricultural specialty of the fertile river valleys, which contain some of the finest farms in the State. The farm bureau of Broome county, organized in Binghamton in 1911, is the oldest in the country. Easy access to large markets, sea and lake ports, coal, steel and raw materials has favoured industrial development. Incoming and outgoing freight amounts to about 1,000,000 tons a year. The annual output of the 258 industries in Binghamton and its suburbs Johnson city and Endicott (2½ and 9m. distant respectively) is valued at \$172,000,000. The leading product is shoes, and the Endicott-Johnson Shoe Corporation is one of the largest in the world, employing 15,000 men and women. Among the other important manufactures are patent medicine, washing-machines, pipe-organs, pianos, cameras, furniture, valves, cigars, kitchen hardware, silk, motion-picture films, computing and tabulating machinery and various articles of iron and steel. The city has about 60 wholesale houses and its retail trading radius of 40m. covers a population of 200,000. Bank deposits amounted to \$270,010,000 in 1926 and the assessed valuation of property was \$114,789,185. A beautiful bridge of reinforced concrete has been built as a memorial to the men who served in the World War. East of the city there is a State hospital for the insane.

The site of Binghamton was in Indian territory until 1770, when a decisive victory was won by General Clinton and General Sullivan at Newtown (now Elmira). An Iroquois village known as Ochenang had been situated here, and the white settlement, dating from 1787, was first called Chenango Point. The greater part of the city stands on land originally included in the "Bingham Patent," a large tract on both sides of the Susquehanna, owned by William Bingham (1751-1804), a merchant of Philadelphia. A village was laid out by his agent in 1800. It was incorporated in 1834, and received a city charter in 1867. Weekly stage service to Newburgh and Owego was established in 1816; the first boat on the Chenango canal reached Binghamton in 1837; and the first passenger train from New York arrived over the Erie, Dec. 26, 1848.

BINGLEY, urban district, West Riding of Yorkshire, England, on the Aire, 5½m. N.W. of Bradford, on the L.M.S. railway. Pop. (1921) 18,942. The area is in the midst of the Yorkshire industrial region, but in spite of the many factories it still retains much open land in the Aire Valley, and agriculture is an important occupation. Textile working, especially spinning and weaving and worsted manufacture, is important, as well as metal working.

BINIQU or **BIGNOU**, a primitive kind of bagpipe consisting of a leather bag inflated by means of a short valved insufflation tube or blow-pipe. The biniou is still the traditional and popular instrument of the Breton peasants of Cornouailles and Morbihan, Brittany. (See BAG-PIPE.)

BINMALEY, a municipality (with administration centre and 18 barrios or districts), of the province of Pangasinan, Luzon, Philippine Islands, on the delta of the Agno river, about 5m. W. of Dagupan which has railway connections with Manila. Pop. (1918), 18,243, of whom 9,140 were males and none white. It has important fisheries, and manufactures salt, pottery, thatch (made of nipa palm leaves) and nipa wine. Rice and coconuts are the principal agricultural products. In 1918 it had 546 household industry establishments with output valued at 102,200 pesos, and 25 schools, of which nine were public. The language is Pangasinan.

BINNACLE: see NAUTICAL TERMS.

BINNEY, EDWARD WILLIAM (1812-1881), English geologist, was born at Morton, Nottinghamshire. He was articled to a solicitor in Chesterfield, and in 1836 settled at Manchester. On the Coal Measures he became an acknowledged authority, and wrote *Observations on the Structure of Fossil Plants found in the Carboniferous Strata* (1868-75). His large collection of fossils was placed in Owen's College. He died at Manchester on Dec. 19, 1881.

BINNEY, HORACE (1780-1875), American lawyer, was born in Philadelphia, Pa., on Jan. 4, 1780. He graduated at Harvard college in 1797 and then studied law in the office of Jared Ingersoll (1749-1822), who was attorney general of Pennsylvania. Binney was admitted to the bar in Philadelphia in 1800. He served in the Pennsylvania legislature from 1806-07. His most famous case, *Bidal v. Girard's Executors*, in which he was unsuccessfully opposed by Daniel Webster, greatly influenced the interpretation of the law of charities. During the Civil War he issued three pamphlets (1861, 1862 and 1865), justifying Abraham Lincoln in his suspension of the writ of *habeas corpus*.

See the *Life of Horace Binney* (Philadelphia, 1903), by his grandson, C. C. Binney.

BINNEY, THOMAS (1798-1874), English Congregationalist divine, was born of Presbyterian parents at Newcastle-on-Tyne. He entered the theological school at Wymondley, Herts, now incorporated in New College, Hampstead. In 1829, after short pastorates at Bedford (New Meeting) and Newport, Isle of Wight, he accepted a call to the historic Weigh House chapel, London. Here he became very popular, and it was found necessary to build a much larger chapel on Fish street Hill, to which the congregation removed in 1834. An address delivered on the occasion of the laying of the foundation stone was published, with an appendix containing a strong attack on the influence of the Church of England, which gave rise to a long and bitter controversy. In 1845 he visited Canada and the United States, and in 1857 the

Australian colonies. He was twice chairman of the Congregational Union of England and Wales, and only resigned his pastorate in 1869 at the age of 72. He died on Feb. 24, 1874.

Binney gave a special impulse to congregational psalmody by the publication of a book entitled *The Service of Song in the House of the Lord*. He wrote much devotional verse, including the well-known hymn "Eternal Light! Eternal Light!"

BINOCULAR INSTRUMENT, an optical apparatus or instrument through which objects are viewed with both eyes. Such instruments can be conveniently dealt with as belonging to

FROM GLEICHEN, "DIE THEORIE DER MODERNEN OPTISCHEN INSTRUMENTE" (ENKE)

FIG. 1.—PORRO'S REVERSING PRISM

two classes: (1) Instruments for viewing solid objects or objects in space. (2) Instruments for the presentation of plane views to both eyes for the purpose of obtaining a stereoscopic view of the subject, i.e., an impression of depth. The natural vision is such that different central projections of the objects are communicated to both eyes, the difference of the two perspective representations arises from the fact that the projection centres are laterally displaced to an interval about equal to the distance between the eyes (the interpupillary distance). Binocular instruments should aid the natural vision with both eyes. If objects be so far distant that the two perspectives formed by the naked eye are no more distinguishable from each other, recourse may be had to binocular field glasses or telescopes, and if the objects be so small that in order to observe details on them the eyes must be brought so close to the objects that they cannot accommodate to the images recourse may be had to binocular microscopes and magnifiers.

The construction of binocular instruments dates back over several centuries and has now been brought to great perfection. The subject of their theory and history has been exhaustively treated by M. Von Rohr *Die binocularen Instrumente* (1907) the first publication to present a complete account of these instruments.

TELESCOPE

Early History.—The first binocular telescope, consisting of two telescopes placed side by side, was constructed in 1608 by

FIG. 2.—BOULANGER'S BINOCULAR TELESCOPE, 1859. THE FIRST IN WHICH THE PORRO PRISM COMBINATION WAS UTILIZED FOR THE PURPOSE OF ERECTING THE IMAGE

Johann Lepperhey, the inventor of the ordinary Dutch telescope, i.e., the combination of a collective lens as an objective and a dispersive lens as an eyepiece. The subject was next taken up by the monks The Capuchin Antonius Maria Schyrllaues de Rheita (A. M. Schyrl) (1597-1660) described in 1645 the construction of double terrestrial telescopes. Greater success attended the efforts of the Capuchin Cherubin d'Orleans who flourished a little later. He constructed large double telescopes of the Dutch type for use in war and small instruments of lower magnification. He introduced great improvements into these telescopes by providing them with adjustments to enable the

interocular distance to be adapted to suit individual observers, and the object glass distance to suit far and near objects.

After these discoveries the subject received no more attention until the 19th century. The re-invention of the Dutch binocular telescope apparently dates from 1823, and is to be assigned to the skilful Viennese optician Johann Voigtlaender. He received a kind of patent for an instrument having two Dutch telescopes so arranged that the axes of both were parallel and in line with

the eye-centres. Both telescopes had independent focussing adjustments for both eyes. A year and a half later another Viennese optician B. Weidholt obtained a patent for an arrangement of

FROM GLEICHEN, "DIE THEORIE DER MODERNEN OPTISCHEN INSTRUMENTE" (ENKE)

FIG. 3.—MODERN PRISM BINOCULAR

two Dutch telescopes with their axes parallel but adjustable for interocular distance, but the credit of having placed these instruments on the market probably belongs to J. P. Lemièrre, in Paris, who in 1825 took out a French patent for an improvement of the Dutch double telescope. Lemièrre's instruments were furnished with a common central focussing adjustment and the adaptation to the interocular distance was effected by turning the two parallel bodies round their common axis. During the next

few decades very few improvements in this type of instrument are recorded. The last improvement was apparently made by P. G. Bardout, who combined two terrestrial tubes using Lemièrre's method of mounting them parallel to a common axis with interocular adjustment and central focussing arrangement for both eyes. It was possible for him to achieve greater magnifications with his instruments.

The Prism Combination.—Ignazio Porro (1795-1875) invented in 1851 a prism combination which was to play an important part in the future development of binocular instruments. The prism combination consists of two right-angle prisms placed with their hypotenuse faces adjacent, having the planes of total reflection at right-angles to one another (fig. 1). An image viewed through such a prism will appear completely reversed. A. A. Boulanger was the first to utilize the Porro prism combination in his binocular telescope (fig. 2) for which he obtained a patent in France in the year 1859. The prism combination was mounted above the objective of the telescope in such a manner that, by means of a right- and left-hand screw, the interocular distance could be adjusted to suit the observers. He overlooked, however, the possibility of mounting the Porro prisms in such a manner as to increase the distance between the objectives relatively to the eyepieces, thereby gaining enhanced stereoscopic effect. C. Nachet introduced this improvement in 1875, but he also does not seem to have realized that any gain in stereoscopic effect would result therefrom as no mention of this is made in his patent. His instruments did not meet with much popularity.

E. Abbé took the matter up *de novo* in 1893 when he designed prism binoculars and telescopes. His constructions were the forerunners of the modern type of prism binocular. If the Porro prism combination (fig. 1) is examined closely it will be seen that it contains two great advantages. Abbé made use of both by mounting them so that he obtained a greater distance between the objectives than between the eyepieces, and by separating the

FIG. 5.—Prism binocular with Abbé's direct vision reversing prism

FIG. 7.—Prism binocular with a type of reversing prism designed by Dabresse

prism combination (fig. 1) is examined closely it will be seen that it contains two great advantages. Abbé made use of both by mounting them so that he obtained a greater distance between the objectives than between the eyepieces, and by separating the

hypotenuse faces one from the other he shortened the telescope considerably in overall length. Abbé's binoculars had an object-glass distance of $1\frac{1}{2}$ times to twice that of the eyepieces concurrently with great tube shortening, making the binocular very compact (fig. 3).

The type has undergone many and varied improvements. Beginning with small objectives and eyepieces giving an angle of 36° at the eye, it has now been developed by many constructors into a high precision optical instrument with considerably larger objectives and eyepieces of double the original field of view, without destroying the compactness and handiness of the instrument.

A great number of other reversing prism combinations have been utilized, being derived mostly from the form originally designed by Amici (fig. 4). It is unknown when this prism was designed by Amici, but it is known that he himself used it in such a way that the incoming and outgoing ray traversed the entrance and exit faces at right-angles to their planes, and became totally reflected on the roof, thereby causing a reversal of the image from right to left and by letting the incoming ray make an angle of 90° with the outgoing ray, the reversal in the vertical direction was accomplished. This type of reversing prism has become known as the "roof prism." It has to be made with great accuracy, the two faces forming the roof have to be at right-angles to one another within 2 seconds of arc and the line where the roof joins has to be free from imperfections. A number of roof prism combinations have been designed to obtain direct vision or at any rate parallelism of the entrance and exit beams, notably by Abbé, Sprenger, Daubresse and others (figs. 5, 6, 7 and 8). All these constructions have been used with more or less success in prism binoculars.

Fig. 5 shows a complete binocular with Abbé's direct-vision reversing prism. This type does not increase the stereoscopic power beyond that due to the magnification, since eyepieces and object-glasses are equal distance apart. Fig. 6 embodies two Sprenger prisms, the peculiar construction of which enables the object-glasses to be separated widely, giving correspondingly increased stereoscopic effect. Fig. 7 shows a prism binocular with two modified Daubresse prisms, with very slightly increased object glass separations. Fig. 8 shows a binocular with two roof prisms, having 6 internal reflections, which for the sake of compactness have been so arranged that the distance between the objectives is less than that of the eyepieces, the stereoscopic effect in this case being less than that due to the magnification alone. The Porro reversing prism, shown in fig. 1 is capable of further modification in use if its compound parts are separated (fig. 9). If the object glass is placed in the entrance beam either

FROM GLEICHEN, "DIE THEORIE DER MODERNEN OPTISCHEN INSTRUMENTE" (ENKE)

FIG. 8.—OPTICAL ARRANGEMENT OF PRISM BINOCULAR WITH REDUCED STEREOSCOPIC EFFECT

in front or below the isolated upper prism, the distance between the eyepiece and objective can be increased at will. By combining two such instruments as a binocular (fig. 10) the stereoscopic effect will be increased in accordance with the ratio of interocular distance to object glass distance. Furthermore these instruments are suitable for much higher magnifications than those previously described.

The Stereoscopic Effect.—A great many uses have been found for the type of telescope shown in fig. 10. On account of the greatly increased objective separation, up to 18 and more times the interocular distance, the stereoscopic effect of such instruments is very considerable, and gives the user a perception

of depth, *i.e.*, enables him to distinguish objects in different planes at distances of many miles. For this reason it is used largely for artillery purposes at sea and on land. By making both telescopes move round an axis placed centrally to the eyepieces, the two objectives can be brought from a horizontal to a vertical position to enable the user to remain under cover and use the instrument in the manner of a periscope.

For measuring purposes instruments of the type shown in fig. 10 with a horizontal axis have been largely used. The measurement is effected by using in conjunction with the space or interval to be measured some means of measurement; *e.g.*, a movable pointer or a fixed scale. This instrument shows a transition to the stereoscope inasmuch as the scale or means of measurement is not directly observed, but to each eye a plane representation is offered just as in the stereoscope; the space to be measured on the other hand is portrayed in exactly the same way as in a double telescope. The method of superposing the two spaces on one another was deduced by Sir David Brewster in 1856, but he does not appear to have dealt with the problem of measurements.

Hector de Groussillier in conjunction with E. Abbé and C. Pulfrich designed the first stereoscopic rangefinder suitable for prac-

tical use. The power of perception of depth by the human eye is most accurate. This has been ascertained by the approximately equal keenness of vision of all normal-sighted people and by the interpupillary distance. The angle which serves as a measure for the keenness of vision is that subtended by two neighbouring points of an object space which are just seen by the single eye as a double point; for smaller angles they merge into one. According to the older experiments of Helmholtz this angle is about one minute. When measured on the retina the keenness of vision

FROM MULLER-POUILLET, "LEHRBUCH DER PHYSIK" (VIEWEG AND SON)

FIG. 11.—PLAN OF A TELESTEREOSCOPE BY HELMHOLTZ, 1857
Two reflections under 45° to the line of sight enable great stereoscopic effect to be obtained, as the eyes, which are at A A', appear to be at O O'

is determined by the diameter of the nerve filaments situated in straight rows close to one another in the fovea. The diameter of these filaments is roughly 0.005 mm., or, in angular measure, one minute. More recent experiments for keenness of vision and power of perception of depth have given considerably higher values; thus Pulfrich in 1899, when first introducing stereoscopic instruments for measuring distance, proved that as a rule persons with normal eyes have a power of separation of 10 seconds and sometimes even less.

There are two methods of extending the limits of stereoscopic vision and of increasing the accuracy of the perception of depth, (1) by augmenting the keenness of sight by the aid of telescope or microscope, and (2) by increasing the interpupillary by several reflections after the plan shown by Helmholtz in 1857 (fig. 11) which shows his telestereoscope but without telescopic magnifying power. By combining telescopic magnification with increased interpupillary distance the type of instrument shown in fig. 10 is evolved. If there is a telescopic magnification of m times or a base magnification of n times, *i.e.*, the distance between the

FIG. 12.—OPTICAL SYSTEM OF RIDDELL'S BINOCULAR MICROSCOPE

objectives is n times the interpupillary distance, then the radius of stereoscopic vision is increased m or n times with respect to that of the naked eye; and, if both are active, $m \times n$ times. The action of telescopic magnification m and base magnification n are however fundamentally different from one another. In the first case the areal dimensions are diminished in the same proportion as the distances are lessened, whilst in the other case the real dimensions remain unchanged, with the result that three dimensional images in the binocular vision space of an observer using such an instrument appear as a model proportionately diminished in all its dimensions and brought nearer to the observer, but pushed together to the front like the wings on the stage of a theatre. This effect is present in all stereoscopic binoculars and telescopes.

MICROSCOPE

The first binocular microscope was invented by the previously mentioned Father Cherubin, whose instrument consisted of two inverting systems and consequently gave a totally wrong impression of depth, *i.e.*, the depressions appeared as elevations and vice versa or, according to Charles Wheatstone's phrase, it presented a *pseudoscopic* impression. This quality was not recognized by the microscopists of the time. The instrument subsequently fell into complete neglect for nearly two centuries, to be revived in 1852 by Charles Wheatstone. The publication of his views in his second great paper on "Binocular Vision" (*Phil. Trans.* 1852) undoubtedly stimulated the investigation of this instrument, which was carried on with zeal and success more especially in England and the United States of America. In 1853 the American J. L. Riddell published a description of his binocular microscope which contained the essentials of Wheatstone's pseudoscope. Wheatstone tried without success to interest Andrew Ross and Hugh Powell, the two most important microscope makers in London, in the binocular microscope.

Some time later, however, F. H. Wenham became interested. He was not only a gifted amateur but also a technician having a particular interest in the advancement of the microscopes, and his theoretical insight in the subject was remarkable. His endeavours however bore fruit only in the next decade, but in a way which was decisive for the adoption of the binocular microscope in England at any rate. His first construction was almost identical with that of J. L. Riddell (fig. 12), but this type he only considered useful for binocular magnifying glasses. He tried to use Riddell's arrangement between the objectives and eyepieces but

FROM ROHR, "DIE BINOKULAREN INSTRUMENTE" (SPRINGER)

FIG. 13.—WENHAM'S ACHROMATIC PRISM FOR BINOCULAR MICROSCOPE. IT GAVE PSEUDOSCOPIC IMAGES

he could not avoid the pseudoscopic effect. The same defect adhered to his first achromatic refracting prism (fig. 13) interposed between the eyepieces and objectives of the microscope.

In the spring of 1860 he brought out his first binocular microscope (fig. 14) with *orthoscopic* representation. He arranged the achromatic refracting prism so that the emergent rays crossed over on their way to the eyepieces so that the rays from the left side of the objective entered the right eyepiece and vice versa. This binocular microscope had the disadvantage of not being able

to be used as a monocular microscope, and Wenham published in Dec. 1860 a description of his reflecting prism (fig. 15). When placed close behind the objective it directs the rays coming from the right half of the objective after two reflections into the left eyepiece of the microscope; those coming from the left half of the objective go straight into the right eyepiece (fig. 16).

FIG. 14.—SYMMETRICAL BINOCULAR MICROSCOPE TUBES

FROM ROHR, "DIE BINOKULAREN INSTRUMENTE" (SPRINGER)

FIG. 15.—WENHAM'S REFLECTING PRISM FOR BINOCULAR MICROSCOPES

depth. Wenham's prism form is shown in fig. 17. He split each beam from the objective into two portions, one going straight through the prism block, and the other being reflected on a prism surface bounded by a thin air-space, and then totally reflected on the further side of the prism to be directed into the other tube. E. Abbé's eyepiece construction followed these lines closely (fig. 18). The eyepiece without special arrangements did not present a stereoscopic image of the object but afforded simply binocular vision; by adapting special diaphragms over the eyepieces the image could be made to appear either orthoscopic or pseudoscopic, according to whether the outer or the inner halves of the exit beams of the two eyepieces were allowed to enter the observer's eye. A fundamentally different type of binocular microscope (fig. 19) with orthoscopic representation of the image has been designed by H. S. Greenough by employing two separate tubes, each complete with objective and eyepiece, together with a Porro prism system to erect the images. By making these Porro prisms rotate round the tube axis the interocular distance could be adjusted to suit the observer.

FIG. 16.—UNSYMMETRICAL BINOCULAR MICROSCOPE TUBES

By making these Porro prisms rotate round the tube axis the interocular distance could be adjusted to suit the observer.

THE STEREOSCOPE

The fundamental property of stereoscopic vision, or simultaneous vision with both eyes, is the direct perception of relative

distances of near objects. Even by the use of one eye it is possible to obtain an impression of depth or relative distance, but this is the result of experiences and other considerations. When using both eyes each eye is fixed and accommodated to one particular spot of the object. The angle made by the two lines connecting the right and left eye respectively with the spot chosen on the object varies with the distance of the object. For an object at the distance of 10 in. (normal vision) the angle would be about 15° , and it decreases as the object moves away from the observer, until it reaches zero when the object is at an infinite distance. The two images of a near object formed on the retina are dissimilar as is quite evident, and, as each eye transmits its respective picture to the brain, their dissimilarity creates the perception of depth or distance.

The greater the distance of the object the less will be the dissimilarity between the two images. If we take $\frac{1}{2}$ minute as the usual angle which two lines must subtend at the eye to be seen separately, rather than as one line formed by a blending together, it has been shown that stereoscopic vision for a normal sighted person ceases between 400 and 550 yd., according to the interpupillary distance. It is possible to convey the impression of depth by offering to both eyes plane representations of three dimensional objects, by, for instance, taking two photographs from the points of rotation of the eyes and by so arranging them in an instrument that each eye sees its respective picture without being able to see the other one. Such an instrument is called a stereoscope.

Construction of Various Types.—

C. Wheatstone first observed the stereoscopic effect, in 1833, and was the first scientist to construct such an instrument, which he described in his paper in 1838. A principle of the instrument is shown in fig. 20. A later type of his stereoscope, evolved in 1852, differs from the original model in that the pictures can be placed at different inclinations to the mirrors and at different distances from them, in order that the pictures may be observed under exactly the same inclination of the image and the same angle of convergence as when the picture was taken. Other mirror stereoscopes were made by H. W. Dove, Sir David Brewster, and others. These mirror stereoscopes had no practical result worth mentioning on account of their awkward shape and the difficulty in obtaining equal illumination of both pictures. It was also inconvenient that the pictures had to be placed separately and reversed in the apparatus. The disadvantage that the picture to be observed in the mirror must be reversed can be obviated by rotating the correct picture through 180° in its own plane and placing it in the position of the picture L (fig. 21) and by using a so-called "roof-prism" in the place of the mirror s_2 , as suggested by Pulfrich. Sir David Brewster took up the stereoscope in 1849, and in a paper read in that year proposed his prism lens stereoscope in which he used eccentric portions of double convex lenses for viewing the half pictures. The first instrument of this type was made by A. Ross in the same year, but created no interest whatever amongst the public. It was only after J. Dubosq of Paris

FROM ROHR, "DIE BINOKULAREN INSTRUMENTE" (SPRINGER)
FIG. 17.—WENHAM'S REFLECTING PRISM FOR MICROSCOPES WITH BINOCULAR VISION WITHOUT STEREOSCOPIC EFFECT

FIG. 18.—ABBÉ'S BINOCULAR EYEPIECE, A DERIVATION FROM WENHAM'S REFLECTING PRISM (FIG. 17)

FIG. 19.—GREENOUGH'S BINOCULAR MICROSCOPE, MADE ON THE LINES OF A BINOCULAR TELESCOPE

had taken up the regular manufacture that the instrument became very largely used. The causes of its success were its convenient form and the fact that a series of adjusted stereoscopic pictures (landscapes, machines, etc.) could be observed in rapid succession.

Brewster's stereoscope made an observation of stereoscopic pictures possible when the distance between identical points on both pictures was considerably greater than that between the observer's eyes. If the lenses shown in fig. 22 on the focal plane of which the image is formed are large enough, and the distance between the image points A_1 and A_2 is not greater than the distance between the centres of the two lenses (avoiding the divergence of the axes of the eyes), then the distance between the eyes is secondary and the observer sees the distant points with the axes of the eyes parallel. These apparent advantages however are counterbalanced by the fact that the picture seen through the lenses is eccentric and consequently an incorrect impression is obtained and an aberration in the three dimensional images occurs. Wheatstone showed later in his controversy with Brewster that this disadvantage in the lens stereoscope could be avoided by adjusting the lenses and distant points to the distance between the observer's eyes. This same condition was fulfilled in the "double verant," constructed by V. Rohr and Koehler (1905), in which the lenses in accordance with A. Gullstrand's rule are so arranged that the centre of rotation of the eye always coincides with the nodal point of the lens. If everyone had the same interpupillary distance there would be nothing more perfect than this stereoscope.

Helmholtz showed in 1866 that stereoscopes should be so designed that the image of, for instance, a landscape should be shown in the stereoscope to appear to be at infinite distance; he designed his lens stereoscope accordingly. The instrument is shown in fig. 23, and consists of a box similar to Brewster's stereoscope, but it contains complete convex lenses for the eyepieces, the upper lens of about 5 in. focus, the lower of 7 in. focus. Combined these lenses gave a focal length of $2\frac{1}{2}$ in. to the eyepieces. The complete combination was used for viewing pictures on glass which had been photographed with a pair of lenses having a focal length of $2\frac{1}{2}$ inches. Two adjustments were provided for the eyepieces—one in the direction of the optical axis for focusing, and another at right-angles thereto for the interpupillary distance. If the stereoscope was to be used for viewing pictures which had been taken with 5 in. focus lenses, the upper lenses of the eyepieces alone were used, after the lower element in each eyepiece had been removed.

A reversed stereoscopic effect can be obtained by the use of Wheatstone's pseudoscope (fig. 24). If two right-angle prisms are placed in front of the eyes with their hypotenuse surfaces parallel, or nearly so, and in line with the direction of sight, and the apparatus be directed on an object in the middle distance, then objects farther away will appear small and near, while objects near will appear larger and farther away. These pseudo-stereoscopic phenomena are of great importance for the study of the principles of stereoscopy, for they demonstrate that the perception of depth can be aided by direct presentation and hindered by reverse presentation.

The problem of making one stereoscopic picture visible to several people simultaneously can be met in various ways, most simply by portraying the two stereoscopic pictures in different colours one close to the other and giving each observer spectacles of different coloured glass or other transparent material with which it is only possible to see one picture with each eye. The latest development of this method has been the presentation of

stereoscopic cinematograph films to large audiences. The film is printed in two colours and spectators are provided with suitably coloured spectacles.

Stereoscopic Measurements.—The later developments of stereoscopy have been largely due to the work of E. Abbé and C. Pulfrich who succeeded in constructing apparatus which made it possible to measure three-dimensional objects. The earlier

FIG. 22.—HALF LENSES OF BREWSTER'S STEREOSCOPE, ILLUSTRATING THEIR ACTION WHEN VIEWING PICTURES WHICH ARE LARGER THAN THE INTEROCULAR DISTANCE $A_1 A_2$

suggestions for making the stereoscope a measuring instrument were not realized, though decisive improvements were made

Brewster was unconsciously near the solution of the problem when he prepared ghosts of vistas by placing one transparent picture over another. More important than these trivial pictures are the superposed pictures (of cone sections, machines, anatomical preparations, etc.) in which sections of the same solid object are successively photographed on one plate, so that in a stereoscope one could see as it were through the opaque surface of the solid into the interior

To A. Rollett (1861) is due the merit of constructing the first stereoscopic measuring scale. It was a form of ladder, apparently extending into space, whose rungs gave the distances of the objects. J. Harmer (1881) used a scale of depth, consisting of a series of squares arranged one behind the other, in order to measure in the stereoscope a picture of the clouds taken with a large base line of about 15 metres. N. F. Stolze (1884 and 1892) placed gratings in front of the two half pictures of a mirror stereoscope, one of which could be moved by a micrometer. He thus discovered the device called the "travelling mark."

FIG. 23.—HELMHOLTZ'S STEREOSCOPE

The pictures placed at A are examined at B_0 and B_1 through eyepieces of different focal lengths, which must be adjusted in accordance with the focal length of the lens with which the pictures were taken

Of the practical application of stereoscopy we may note the stereoscopic rangefinder already dealt with under the paragraph for telescopes, the stereocomparator devised in 1901 by C. Pulfrich, and the stereoscopic measuring machine, invented by H. G. Fourcade of Capetown 1902, which is similar to the stereocom-

parator in many points. These instruments inaugurated the successful measurement of the distances of objects in space. Measurement is not made on the objects themselves but on photographic plates which are taken with special instruments, field and stand phototheodolites, at the extremities of a base-line which is always selected according to the distance of the object and the exactitude of measurement needed. For measuring the pictures a binocular microscope adjusted to the dimensions and the distance between the two plates is used, and a fixed mark is placed in each image plane; these marks combine in binocular view to a virtual mark in the three dimensional images. If the plates are

FIG. 24.—WHEATSTONE'S PSEUDOSCOPE, WHICH PRODUCES A WRONG PERCEPTION OF DEPTH

correctly adjusted the so-called travelling mark can be placed on any point of the landscape, and then used for the measurement of solidity of the objects or the production of plans and models, just as formerly, for example, the measuring staff was used for geodetic observations, with the difference that in the stereocomparator the mark is regulated by the observer only, and is not hindered in its movements by any undulations, etc., of the land.

Applications.—The stereocomparator has a large number of applications; e.g., in mountain photography, coastal measurements, photographing a battle from a ship, geodesy, the study of the waves, investigating the trajectory of a shot, and it is also utilized in railway building or on voyages of discovery, etc. A further advance has been made in the stereophotogrammetric method by providing the stereocomparator with a drawing apparatus (F. C. Thomson, E. Orel, Carl Zeiss and others) with which contours

The two pictures placed on P_1 and P_2 are seen at A either simultaneously or individually by alternately opening the shutters B_1 and B_2 . Differences in the two pictures can be easily distinguished thereby

can be automatically drawn from the stereophotogrammetric photographs. As a further application of stereoscopy we may note the utilization of optical effects and disturbance of stereoscopic vision (agitation and lustrous appearances) in the discovery of differences and alterations in pictures. The method was first used by Brewster to recognize irregularities in carpet patterns, and later by Dove and others for distinguishing the original from a copy for testing coins, cheques, etc. Moreover, with the development of celestial photography, the stereoscope came to be applied to the discovery of planets, comets, variable stars, errors in plates, the proper motions and parallaxes of the fixed stars. Indeed a planetoid discovered by its aid was named Stereoscopia in recognition of this application

Since 1904 binocular observation of stellar plates to determine differences in the images of the objects reproduced has been gradually discarded for the method, derived by Pulfrich, which consists in the monocular observation of the two plates in the

stereocomparator with the assistance of the so-called "blink" microscope (fig 25). In this microscope the two pictures are seen simultaneously or individually by alternately opening the screens B_1 and B_2 . All differences of the images are immediately distinguished by a sudden oscillation of the image point, or by a sudden appearance and disappearance of single points, as in the case of flashlights at sea or the modern illuminated sky lights

in towns, and there is now no difficulty in discovering new planets, comets and variable stars by this method.

C. Pulfrich (1912) describes a new form of reflecting stereoscope (fig. 26) in which the main object of the design was to provide stereoscopic apparatus for the examination of large pictures, notably those produced for stereophotogrammetric work and photographs taken by aircraft for the purposes of survey, etc. The instrument resembles the Wheatstone stereoscope (fig. 20), but with the simple reflecting mirror replaced by two mirrors, set at an angle in front of the observer's eyes, whereby the rays are reflected twice and deflected through an angle of 120° . The two mirrors in each half of the instrument have with advantage been replaced by a prism made from a solid block of glass. The instrument can be used for paper pictures, or for plates, and is arranged with revolving plate holders for the orientation of photographs taken from aircraft.

BINOCULAR VISION: see VISION.

BINOMIAL FORMULA. Binomial theorem is the name attached to an algebraic formula widely used for transforming and simplifying algebraic expressions and also in processes of approximation.

Positive integral exponents. If a and b stand for any real numbers, and n is a positive integer, then the binomial $(a+b)$, raised to the n th power, can be "expanded" by the formula,

$$(a+b)^n = a^n + na^{n-1}b + \frac{n(n-1)}{2!}a^{n-2}b^2 + \frac{n(n-1)(n-2)}{3!}a^{n-3}b^3 + \dots + nab^{n-1} + b^n. \quad (1)$$

By actual multiplication the expressions are easily obtained:—

$$(a+b)^2 = a^2 + 2ab + b^2, \quad (a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3, \\ (a+b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.$$

The same results are obtained by substituting for n in Formula 1 successively the values 2, 3, and 4. In other words, Formula 1 is a generalization of the three special cases obtained by multiplication. By the aid of Formula 1 it is possible to dispense with the process of multiplication, which becomes tedious when n is large; the expansion can be written down provided the changes in the exponents and coefficients of the successive terms are observed. These changes are seen to be in accordance with the following laws: (1) the exponents of a are for the successive terms $n, n-1, n-2, \dots, 1$, and finally 0 (not written, because $a^0=1$); that is, the exponent of a is n for the first term, and diminishes by unity in each successive term; (2) the exponent of b is 0 in the first term (not written, because $b^0=1$), and is 1, 2, 3, $\dots, n-1, n$ for the terms following; (3) the coefficients are formed according to a slightly more complicated rule. The coefficient of the first term is 1, and that of the second term is n . The coefficient of the third term is obtained by multiplying the coefficient of the second term (n) by the exponent of a in that term ($n-1$), and dividing the product by 2, the number of that term in the series; thus one obtains $\frac{n(n-1)}{2}$. The coefficient of the fourth

term is similarly obtained from the third term. Or, generally, the coefficient of the r th term is obtained by multiplying the coefficient of the $(r-1)$ th term by the exponent of a in the $(r-1)$ th term, and dividing the product thus obtained by $r-1$. In this manner there follows the general expression for the r th term of the expansion, namely $\frac{n(n-1)\dots(n-r+2)}{(r-1)!} a^{n-r+1}b^{r-1}$ by the aid of which any term may be written. Thus, if we desire the

4th term, we substitute 4 for r and obtain that term as given in Formula 1. Observing these three rules, it is possible to write down the expansion of a binomial for any power.

Fractional and negative exponents. When the exponent n is a positive fraction, a negative fraction, or a negative integer, the binomial formula retains the same form as above, except that there is no last term b^n . In other words, the series now has an unlimited number of terms and is an "infinite series." That there is no end to the series becomes evident from the fact that the coefficient for the r th term, $\frac{n(n-1)\dots(n-r+2)}{(r-1)!}$, does not

become zero when the exponent n is not a positive integer. For example, if $n=\frac{1}{2}$, none of the factors, $(n-1), (n-2), \dots, (n-r+2)$, vanishes, and hence the r th term does not become zero, no matter how large a positive integral value r may represent. For the simpler case which we considered first, when n is a positive integer, say 5, it is easy to see that a term beyond the 5th, say the 7th term in the expansion, has in the numerator a factor $(5-7+2)$ which is zero; hence there really is no 7th term. The same factor zero occurs when r is taken to represent the 8th, 9th, or a term still higher. Thus, for $n=5$, there is a last term in the expansion, namely b^5 . Thus far we have considered only rational values of the numbers a, b , and n , but the binomial formula is applicable to irrational values.

Sometimes it is convenient to change the form of the binomial formula by letting $a=1$, and $b=x$, a variable. Since all the powers of 1 are 1, the expression becomes, if we also insert the r th term,

$$(1+x)^n = 1 + nx + \frac{n(n-1)}{2!}x^2 + \dots + \frac{n(n-1)(n-2)\dots(n-r+2)}{(r-1)!}x^{r-1} + \dots \quad (2)$$

When the expansion is an infinite series, the theory of the binomial formula becomes much more difficult. In fact, the expanded form on the right side of the equality sign can be said to be equal in arithmetical value to $(a+b)^n$ or to $(1+x)^n$, on the left side, only when the series is "convergent"; that is, when the sum obtained by adding more and more successive terms of the series approaches a definite finite value as a limit. When that sum does not approach a limit, the infinite series is not convergent, but "divergent," and the series is no longer equal in arithmetical value to $(a+b)^n$ or $(1+x)^n$. In other words, the sign of equality in the formula holds true only when the infinite series II. is convergent. The series II. is convergent when x is numerically less than 1; it is divergent when x is numerically greater than 1. The intermediate case when x is numerically equal to 1 is less important.

Exponents complex numbers. A still further generalization of the binomial formula is obtained by letting one or all of the letters a, b, x, n represent imaginary or complex numbers, of the type $c+id$, where c and d are real, and where $i=\sqrt{-1}$. The expansion is an infinite series when n is a complex number. Tests of convergence have been found, similar to the ones given above.

History.—The history of the binomial theorem possesses points of interest. For values of a, b , and n , which may be integral or fractional, the formula was first given by Sir Isaac Newton in a letter of June 13, 1676, and explained further in a letter of Oct. 24, 1676, both addressed to H. Oldenburg, then secretary of the Royal Society of London. Newton's notation was somewhat different from that of to-day. The statement is frequently made that the binomial theorem is engraved on Newton's tomb in Westminster Abbey, but there is no such inscription. Newton gave no proof of the theorem, but verified it by actual multiplication and root extraction. The beginnings of the binomial theorem are found long before the time of Newton. The Indians and Arabs used the expansion of $(a+b)^2$ and $(a+b)^3$ for root extractions. Vieta knew the expansion of $(a+b)^4$. B. Pascal derived the binomial coefficients from the method of what is called the "arithmetical triangle," published posthumously in 1665, but the arithmetical triangle is found before Pascal as early as 1303 in a Chinese tract by Chu Shih-Chieh.

The first proof of the binomial formula for the case of positive integral exponents was given by Jakob (James) Bernoulli (1654–1705) in his posthumous work, the *Ars conjectandi*, 1713, p. 80. When the formula is an infinite series, rigorous proofs are much more difficult, because they necessarily involve considerations of convergence. The general proof given by Leonhard Euler (*Novi comment. Petrop.*, vol. xix. for 1774, p. 103) and other writers of the 18th century dealt mainly with the form of the expansion and did not adequately consider the question of the equality of the arithmetical values on the two sides of the equation. The earliest one to give a rigorous proof of the general case was the Norwegian mathematician Niels Henrik Abel, in *Crelle's Journal*, vol. i., 1826, p. 311. It is a remarkable article of 28 large quarto pages, and it establishes the theorem not only when the exponent n is integral, or fractional, or negative, but also when the exponent is a complex number, and when a and b may likewise be complex numbers. (F. C.A.)

BINTURONG (*Arctictis binturong*), the single species of the genus, ranging from Nepal through the Malay Peninsula to Sumatra and Java. This animal is allied to the palm-civets, but differs from that family by its tufted ears and long, bushy, prehensile tail, which is thick at the root and almost equals in length the head and body together (from 28 to 33 in.). The fur is long and coarse, of a dull black with a grey wash on the head and forelimbs. In habits the binturong is nocturnal, inhabiting forests, and living on small vertebrates, worms, insects and fruits.

BINYON, LAURENCE (1869–), English poet, art historian and civil servant, born at Lancaster on Aug. 10 1869, was educated at St. Paul's school, London, and Trinity college, Oxford, where he won the Newdigate prize in 1890 for his *Persephone*. He entered the department of printed books at the British Museum in 1893, and was transferred to the department of prints and drawings in 1895. He was eventually placed in charge of the oriental prints and drawings, and became one of the greatest living authorities on the subject. His principal contributions to the history of art, outside the great official catalogue of English drawings (4 vols. 1898 *seq.*), and that of Japanese woodcuts (1917) in the British Museum, are his various books on Chinese, Japanese and Indian art, and on the drawings and engravings of William Blake, dating from 1906 onwards. But before he became known as an art historian, Laurence Binyon was already famous as the author of a series of volumes of verse, and as a pioneer in an effort, in which he has found few followers, to restore blank verse drama to the modern English stage. The first of these to be staged was *Paris and Oenone* (1906); *Boadicea* was produced in 1925. In 1927 a selection from his earlier books of poems, made by himself, was published with the title of *A Laurence Binyon Anthology*.

BINZ, KARL (1832–1912), German physician, was born at Bernkastel, and after studying under Virchow became, in 1868, professor at Bonn, where he founded the Pharmacological institute. He investigated the physiological action of quinine, alcohol, arsenic and other drugs. His works include a text book on *materia medica* (1866) and lectures on pharmacology (Eng. trans. A. C. Latham, 1895).

BIO-BIO, an inland province of southern Chile, bounded north and west by the province of Concepción, south by Malleco and Cautín, and east by Argentina. It has an area of about 7,700 sq.m. of well-wooded and mountainous country, including, since 1928, most of the former province of Malleco, and exports timber to a large extent. Its population in 1920 was about 190,900, including incorporated parts of Malleco. The great trunk railway from Santiago south to Puerto Montt crosses the western part of the province and also connects it with the port of Concepción. The capital, Los Angeles (pop. [1920] 13,274) is situated about 15 km. E. of this railway and is connected with it by a branch line.

BIO-BIO, a river of southern Chile, rising in the Pino Hachado pass across the Andes, 38° 45' S. lat., and flowing in a general north-westerly direction to the Pacific at Concepción, where it is 2 m. wide and forms an excellent harbour. It has a total length of about 225 m., nearly one-half of which is navigable.

BIOCHEMISTRY. Biochemistry may be defined as the study of the chemical or physico-chemical processes which play a part in the life phenomena of plants and animals. The subdivision of the science of chemistry into a number of special branches, physical, inorganic, organic, biological, etc., has been the natural consequence of the rapid advances in knowledge which have been made since about 1870. Although the study of the chemical aspect of the physiology of living organisms has only been generally termed biochemistry for some 20 years, it is actually one of the oldest branches of chemical science.

Lavoisier.—Disregarding events which occurred before the birth of modern chemistry at the end of the 18th century, we find that Lavoisier, the creator of the new science, himself spent no small portion of his time in prosecuting biochemical research. He showed clearly for the first time that the life-processes of the animal body can be investigated by chemical means, for he proved by quantitative methods that the body temperature is maintained by the combustion of foodstuffs just as the heat generated in the burning of wood or a candle is produced by the oxidation of organic matter. The first half of the next century produced three outstanding figures, whose united labour extended widely the foundations on which the modern study of biochemistry is based. In the first place Liebig, carrying back with him from Paris to Germany the inspiration gained by contact with those who had been students or colleagues of the great Lavoisier, not only established the study of organic chemistry, on which biochemistry is dependent, but himself opened up wide avenues of research on problems of plant and animal chemistry.

Liebig.—In 1837, at the request of the British Association for the Advancement of Science, he undertook to prepare a report on the state of knowledge in organic chemistry. This led to the publication in 1840 of his memorable work *Die Chemie in ihrer Anwendung auf Agrikultur und Physiologie*, followed in 1842 by *Die Thierchemie, oder die organische Chemie in ihrer Anwendung auf Physiologie und Pathologie*. These two classics mark clearly the point at which the study of plant and agricultural chemistry on the one hand, and that of animal chemistry on the other, first attracted wide interest amongst scientists in general and chemists in particular. Hofmann, speaking of this great chemist said, "In the study of biology, vegetal and animal, Liebig was the first to disentangle intricacies that had before seemed problems beyond the grasp of human intellect to solve; and it was one of the grandest results of his philosophical and experimental investigations that he traced amidst the multitudinous and apparently ever-varying manifestations of life, in its countless modifications of kind and degree, the operation of a few simple laws, physical and chemical, affording, by their determinate combination, the precise and proved conditions of vital development, nutrition, growth, and perpetuation from generation to generation, in unaltered individuality."

Claude Bernard and Pasteur.—At this time progress in this field of thought was still hampered by the persistence of ideas favouring the existence of a *vital force*. The first blow to shatter these theories was dealt by Wohler in 1828 when he announced the synthesis from inorganic materials of urea, a typical animal product for the formation of which some influence exerted by the vitality of the organism had, until then, been considered essential. The belief in a *vital force* or *vital principle* would have died slowly had it not been for the brilliant series of researches in experimental physiology that have made the work of Claude Bernard immortal. The third figure is the illustrious Pasteur, whose researches on fermentation, putrefaction and disease revealed not only the organisms that gave rise to these conditions, but also, in many cases, the chemical or physico-chemical changes that occurred.

During the second half of the 19th century researches in plant and animal chemistry were prosecuted with increasing vigour. Unfortunately, however, there was a tendency for the studies in each field to be kept apart from the other, and there were comparatively few investigators of that period who were sufficiently broad in their outlook to attempt to view the problems from the standpoint of the cell rather than from that of the animal or plant.

Much progress was made in both animal chemistry or, as it was usually termed, physiological chemistry, and in plant and agricultural chemistry, but there were few attempts at correlation.

The 20th Century.—The more general appreciation of the need of a wider outlook seems to have become apparent at the opening of the 20th century, when the term biological chemistry or biochemistry began to displace the older terms. In Great Britain the Biochemical Club, now the Biochemical Society, was founded in 1912, six years after the appearance of the first volume of *The Biochemical Journal*. The corresponding scientific journals in the United States and Germany, *The Journal of Biological Chemistry* and *Biochemische Zeitschrift*, also appeared for the first time in that year. The rapid advance of the new branch of chemistry can be illustrated by the growth of *The Biochemical Journal*, of which the first volume (1906) contained 32 papers, amounting in all to 495 pages of printed matter, whereas the volume for 1926 contained 171 papers and a total of 1,376 pages.

Chemical Processes in the Cell.—The study of the chemical processes occurring in living cells or brought about in the external medium by their action has all along been dependent to a very large extent on the rate of advance in our knowledge of organic and physical chemistry. The contents of the cell, known generally as protoplasm, represent to the chemist a mixture of such complexity that despair of ever gaining any clear conception of its actual composition might well be pardoned. Not only is the task one of great difficulty by reason of the wide variety of substances which are to be found present in cells, but also because a large proportion of those compounds exist in the cell in the condition known as the colloidal state. (*See COLLOIDS.*)

Conditions of Progress.—Progress in biochemistry has, therefore, been dependent to a large extent on the rate of advance of knowledge in the neighbouring fields of organic and physical chemistry. One example may make this clear. A large proportion of the solid material of cellular contents is composed of complex nitrogenous substances termed collectively the proteins. No satisfactory theory regarding their significance in living cells could be advanced until information concerning both the molecular structure of the proteins and their physical properties as colloids had been obtained. The former was provided by the classic researches of the great German chemist Emil Fischer, who revealed, by his analytical studies, that the proteins are large, complex molecules formed by the intercombination of a number of amino-acids by virtue of the basic and acidic groupings. Although it is still uncertain whether the only form of linkage between the constituent amino-acids in the protein molecule is that described by Fischer, it is apparent that it is by far the most common and a very important one. His work has given us a general picture of the internal structure of the protein molecule that is in agreement with the vast majority of known facts concerning its chemical properties.

Parallel with these researches in the field of organic chemistry on the constitution of the proteins, extensive investigations were being made in many quarters on the colloidal properties of these remarkable substances. As a result of this work it has at last been possible to attack with reasonable chances of success the major question concerning the rôle of the proteins in the living cell.

In general, it can be seen that advance in biochemistry has followed much the same path that has been traced by the growth of other branches of experimental science. Broadly speaking, the development can be divided into two phases, the descriptive phase and the quantitative phase. In the former period the efforts of investigators were devoted mainly to the isolation of the substances present in living tissues and to the investigation of their nature and properties, whilst in the later phase attention has been more and more given to elucidating their significance in the organism and to the quantitative examination of the dynamics of the reactions in which they are concerned.

The study of biochemistry may be regarded as having very definitely entered the second phase about 1910, for in almost any journal devoted to this branch of science the great proportion of the papers published at the present time are devoted to the study of the dynamics of cellular reactions. The importance of pursuing this line of study must be apparent when it is borne in mind that it

is particularly by reason of the extraordinary complexity and variety of the energy exchanges that occur in even the simplest cell that living matter is best differentiated from non-living.

Definition of Life.—From the earliest time philosophers have attempted to define life, without one wholly satisfactory definition having been advanced. To-day the difficulties of their task can be appreciated because it becomes increasingly evident that there is no clear line of demarcation between the living and the non-living. Nevertheless, as Claude Bernard indicated in his striking essay on the "Phenomena of Life," there are a number of properties of living matter which, taken collectively, serve as a rough and ready means of differentiating it from systems relatively inert. These are: (1) Assimilation and respiration; (2) reproduction; (3) growth and development; (4) movement; (5) secretion and excretion.

Considered singly, it is obvious that no one of these is in itself characteristic of living matter alone, but as yet no system that could be considered in the light of present opinion a non-living one has been found to exhibit all together. It may serve to show the scope of modern biochemistry if examples be given of the application of the new branch of science to the study of the chemical aspect of these phenomena of life.

Assimilation Processes.—The biochemical study of assimilation has somewhat naturally fallen into two sections, depending upon whether plants or animals are being considered. The power possessed by green plants to synthesize complex organic substances from carbon dioxide, water and simple inorganic salts, such as nitrates, sulphates and phosphates, places them in a class apart from other beings and calls for particular study. (*See PHOTOSYNTHESIS.*) The essential difference is, of course, that for the synthesis of organic matter from carbon dioxide a supply of energy is necessary—the reaction being an endothermic one. Comparatively long ago it was recognized that the source of this supply of energy is the sun, but only recently has the knowledge of the nature of the pigments in the leaf, of the absorption of energy in the form of light by these pigments, of the mechanism of absorption of carbon dioxide by the leaf and of the nature of the substances formed during assimilation, enabled biochemists to construct reasonable theories as to the process of photosynthesis in green plants. In this field much remains to be done. In spite of many strong indications that the first step in carbon assimilation is the photochemical reduction of carbon dioxide to formaldehyde, precise confirmation is lacking. The efficiency of the process is also undetermined. Early investigators believed it to be of the order of 3–5%, but Warburg has recently recorded that the value may be much higher under optimum conditions.

Chlorophyll.—There is also the question of the origin of the chlorophyll pigments in relation to their rôle as energy absorbers and transformers. Obviously so complex a molecule as Willstätter's researches revealed chlorophyll to be must have an exceedingly long evolutionary history. From what type of substance is it descended? At a very early period in the history of living organisms it is probable that supplies of energy for assimilation of carbon dioxide and formation of organic substances were derived not from the absorption of solar radiation by suitable pigments, but from simple exothermic chemical reactions of the type exhibited by the existing species of autotrophic bacteria. (*See BACTERIOLOGY.*) These remarkable organisms, amongst which are grouped certain of the sulphur bacteria, the nitrite bacteria and the hydrogen bacteria, possess the power to carry out simple reactions, such as the oxidation of sulphur to sulphates, ammonia to nitrites, and hydrogen to water, and to use the energy liberated by these reactions to effect the conversion of carbon dioxide into organic matter. It is also interesting to note that certain of the sulphur bacteria contain a pigment, bacterio-purpurin, which appears to function somewhat in the manner of chlorophyll in higher plants, when the bacteria are exposed to the light, whereas in the dark these organisms satisfy their energy requirements by the oxidations referred to above. Possibly these species represent the transitional forms that ultimately led to the evolution of the assimilatory system of the green plant. Little as is our knowledge of the synthesis of carbon compounds in green plants, it is pro-

found when compared with that concerning the formation of substances containing other elements, in particular nitrogen. We are, to all intents and purposes, entirely ignorant of the mode of formation in the plant of the great groups of the proteins, alkaloids and plant bases.

Animal Assimilation.—The outstanding fact that the animal organism is essentially analytic and not synthetic as is the green plant, has, of course, been recognized for many years. The study of assimilation by the animal becomes, therefore, to a large extent, the study of the breakdown, or metabolism, as it is termed, of the foodstuffs that are ingested by the organism to supply, on the one hand, the energy for heat production or work and, on the other, the molecular units required to construct or maintain its tissues.

Biochemical investigations of assimilation in the animal world have made rather more rapid progress than corresponding efforts in the field of plant chemistry. To a large degree this is due to the fact that, in the higher animals at least, it is to some extent possible to follow the fate of substances by examining the body fluids, the individual organs, or, more particularly, the excretions.

Food Metabolism and Enzymes.—The study of the metabolism of foodstuffs in the animal body represents a large and important branch of biological chemistry. It entails in the first place an examination of the mode of action of the remarkable catalytic agents possessed by the living cell and termed enzymes (*see ENZYMES*), by means of which the complex molecules of the proteins, polysaccharides, and fats are broken down so that the simpler molecules of amino-acids and sugars can pass through the absorbing membranes of the alimentary canal.

Mechanism of Absorption.—The actual mechanism of absorption of substances into the tissue fluids must then be studied, after which we must enquire into the fate of the molecules that have been assimilated. Some of these go to form tissues that are being constructed, especially during the period of growth; of the others, the great majority are in due course oxidized so that the energy liberated by their oxidative degradation may be available for maintaining body temperature, or for the performance of work. A whole field of biochemistry is concerned with the mechanisms by which organic molecules are oxidized in the living cell to carbon dioxide and water, for a large proportion of the substances that are rapidly and fully oxidized in the tissues at temperatures below 40° C are oxidized only by drastic treatment with chemical reagents and by the employment of high temperatures when subjected to experiment in the test tube.

Respiration Processes.—It was discovered by the researches of Mayow, Priestley and Lavoisier that living creatures support life by the process of respiration, in which oxygen is taken into the system, and the product of oxidation of organic matter, carbon dioxide, is given off. To-day it is recognized that respiration is in no way peculiar to living tissues, for many non-living systems can be constructed that will absorb oxygen and eliminate carbon dioxide under conditions more or less comparable with those under which the living cells respire. The very striking experiment described in recent years by the distinguished German chemist Otto Warburg may be taken as an illustration. The oxidation of certain substances which are oxidized in the body, *e.g.*, certain amino-acids, will take place along apparently similar paths, at any rate leading to the formation of carbon dioxide and ammonia, when their aqueous solutions are shaken with carefully prepared charcoal in a fine state of division. A measure of the oxygen absorbed and of the carbon dioxide evolved in such cases is as truly a measure of the respiration of the charcoal as a determination of the respiratory quotient is an indication of the oxidative activity of a living tissue. The parallel becomes even more remarkable when it is learned that the respiration of the charcoal particles can be depressed by the addition of narcotics or poisons in a manner entirely comparable with the influence of these substances on the respiration of living cells.

Origin of Circulatory System.—The biochemical study of respiration is, however, a problem presenting many aspects. Primarily it is necessary to investigate the means by which the oxygen is brought to the cells, a task that widens on every hand and takes us into many fields. The cells of the simpler forms of

life draw their supplies of oxygen direct from solution in the surrounding fluid, but for more complex organisms this would not suffice, and methods of distributing the oxygen to tissues more remote from the external medium have evolved. Thus arose the circulatory system of animals. Simple air-breathing species dependent on the diffusion into the tissue spaces of oxygen from a more or less complicated system of tracheal tubes, gave rise to more complex organisms requiring the evolution of the lung with its enormous diffusion surface. Even this would have been insufficient to supply the oxygen requirements of the majority of animals if oxygen carriers of the type of haemoglobin had not been evolved to enable the circulating fluid to carry round to the tissues ample oxygen for their needs.

Haemoglobin and Respiratory Pigments.—A field of biochemical research that attracts wide attention at the present time concerns the respiratory pigments, of which the haemoglobins are the best known examples. These substances may serve a dual rôle by acting as oxygen carriers and as catalysts of oxidation reactions. The latter seems particularly true of a remarkable pigment that has been found present in every form of life yet examined. Discovered in 1884 by MacMunn and exhaustively studied by him, its significance, as a substance related to haemoglobin and as an important factor in the oxidation reactions in the cell, which he emphasized, escaped notice until attention was again drawn to it by the recent studies of Keilin. The occurrence of cytochrome, as Keilin has renamed this pigment, in plant as well as animal cells indicates that its significance is probably fundamental; it seems likely that it occupies an important position in the evolutionary history of the haemoglobins. But the interest of the biochemist cannot stop with the study of the mechanisms by which oxygen is brought to the cells or held there; he must enquire how the oxygen is made available in the cell for oxidations.

Action of Oxygen.—Atmospheric oxygen, whether obtained direct from solution in the surrounding medium, or by the dissociation of such a pigment as oxyhaemoglobin, is relatively inert as an oxidizing agent. Of the foodstuffs oxidized in living cells only very few are appreciably attacked by oxygen in the molecular form O₂; the unsaturated fatty acids present in such oils as cod liver oil and linseed oil are examples of compounds that take up molecular oxygen, but the extent to which they are oxidized is very small when compared with the complete degradation to carbon dioxide and water that occurs with ease in the animal body. Early in the 19th century Schönbein, in his studies of ozone, pointed out that oxygen must in some manner be activated before it is able to effect the majority of oxidations, and this view, in one form or another, has formed the basis of the many theories of oxidation that have been advanced since his time. We are still without clear ideas regarding the mechanism of activation of molecular oxygen which the living cell possesses, but the studies of Warburg on tissues and on the charcoal model to which reference has been made suggest that minute traces of iron and possibly of other heavy metals such as copper play an important part in the process.

Oxidative Mechanisms.—This brings us in a natural sequence to refer to the oxidative mechanisms which the living organism possesses. In the first place, there are the oxidizing enzymes, the oxidases, a group of catalysts, many of them of a highly specific character, capable of oxidizing with great rapidity under suitable conditions a wide variety of substances. The biochemical examination of the oxidases has been extensive, and has, particularly in recent years, given us considerable information how molecules such as those of tyrosine, xanthine and uric acid are oxidized. According to the recent work of Thunberg, Battelli and Stern the cell possesses, in addition to the recognized type of oxidase, other types of oxidative catalysts of a thermolabile nature. It would appear, however, from the results of the researches of Sir Gowland Hopkins and of Meyerhof that there are also present in the cells of plants and animals oxidative reductive systems which are thermostable. The remarkable substance glutathione, discovered by Hopkins, probably plays an important part in these last-mentioned systems.

Reproduction.—Turning now to the second characteristic of life in our list, namely, reproduction, we find we are considering a phenomenon which might well, at first sight, appear to be outside the scope of experimental attack by biochemists. Surely in the processes underlying reproduction, if anywhere in the realm of biology, might be traced the "vital force" or "entelechy" that would at almost every turn frustrate experimental attack. The clear demonstration that such is not the case, and that the problems of fertilization and reproduction are no less open to experimental biochemical investigation than those of digestion or respiration, we owe to the remarkable work of the great experimental biologist Jacques Loeb. His investigations on the influence of the composition of the surrounding medium on the reproductive cells of certain marine animals dispel any doubt that many of the problems of fertilization, of specificity and of inheritance will in time be solved, and to a large extent by biochemical methods. (See CYTOLOGY; EXPERIMENTAL EMBRYOLOGY.)

Can this be doubted when we recall that the migration of the sperm to the egg has been shown to be directed by the physico-chemical action of certain substances derived from the latter; that the penetration of the ovum by the sperm can be controlled by altering the composition of the surrounding fluid, even to the extent of permitting the admission of a sperm cell foreign to the egg; that the mechanical act of penetration performed by the sperm, and resulting in the almost explosive outburst of oxidative activity that marks the initiation of fertilization, can be reproduced by perforation with needles so successfully that numbers of male frogs have been reared to adult size from eggs so fertilized? Considering these striking facts, and at the same time bearing in mind the mass of evidence that is accumulating on every side to show how the development of the reproductive cells is under chemical control in the body and how these tissues themselves exert by chemical means a far-reaching control on the development and functions of other tissues, no reasonable doubt can be entertained that the phenomena associated with reproduction are open to biochemical investigation.

Genetic Problems.—Many of the closely associated problems of genetics are also well within the biochemist's purview, as can readily be judged by giving one or two examples. The inheritance of colours, whether we are thinking of the blue, red or purple colours of flowers or the black and brown markings of animals, has been shown to depend on the inheritance of a physico-chemical system capable, under ordinary conditions, of producing the colour. Some of these systems and the mechanism of their action are fairly well understood. The systems may be more or less complex in character, but unless they are complete the mechanism for the production of the colour cannot function normally. Thus, for example, two white flowers from different plants of the same species may lack colour because one component of the colour-producing system is absent. If the missing factor is the same in both cases, crossing will not result in the production of coloured flowers, but if their deficiencies are complementary, the seeds produced on cross fertilization will yield plants with coloured flowers. The mechanisms concerned in the production of both animal and plant colours have been extensively studied *in vitro*, and are to some extent understood.

Growth and Development.—The biochemical study of growth and development has been followed along many paths. The influence of the composition of the soil on plant growth has attracted wide attention ever since the classic researches of Liebig were published. To-day the agricultural biochemist not only studies the significance of the more obviously essential constituents of the soil, such as nitrates, phosphates, etc., but is concerned to no little extent with the influence which apparently insignificant amounts of other substances may have. The curious fact that the broad-bean plant will not grow to full maturity without a minute amount of the element boron being present in the soil is an example of what has already resulted.

Chemical Control.—The biochemical study of the growth and development of animals provides many examples of both these aspects of the chemical control of growth. On the one hand the energy requirements of animals during the period of growth

have been investigated in great detail, whilst on the other, it has been ascertained that a normal development is dependent on the satisfaction of a number of clearly defined requirements.

Growth Factors.—A small but definite amount of the amino-acid tryptophane, a constituent of some, but not all, proteins, is necessary for growth of young animals, and the provision of any amount of a protein deficient in that particular building stone will fail to induce growth unless the missing unit is provided from some other source. Many biochemists at the present time are engaged in investigating the remarkable influence which the substances known as the vitamins have on the growth and nutrition of animals. The number of these substances that are generally accepted as being clearly differentiated is already five and probably more exist as yet undiscovered. Their chemical nature remains unknown, and we are also ignorant as to the actual part they play in the economy of the organism. (See VITAMINS.)

Lastly, there is a chemical aspect of growth in the investigation of the influence of inorganic elements on animal development. Problems such as the rôle of traces of iodine in inducing normal development of the thyroid gland, and the manner in which lime salts are deposited in growing bone illustrate the type of question in this field that calls for an answer from biochemists.

Movements.—Study of the chemical or physico-chemical factors inducing the movements of plants and animals covers a wide field of experimental research, ranging from control of the movements of free-swimming unicellular organisms to the unravelling of the complex series of events that occur during a muscle twitch in higher animals.

Little is known, at the present time, of the factors determining the growth movements of plants beyond Loeb's having shown by his researches on regeneration in *Bryophyllum* that chemical factors probably play a part in the directional growth of shoots and roots. The movements of many forms of simple animals can be to a certain extent controlled by making alterations in the composition of the medium in which they exist, as, for example, when the water flea, *Daphnia*, which normally swims away from the light moves in the reverse direction when carbon dioxide is bubbled through the water. Another remarkable example also described by Loeb is that of the larvae of *Porthesia*, which in the starving condition are attracted toward light and climb high up the stems of the plant on which they customarily feed, but which, having fed on the leaves, become negatively heliotropic and at once descend again to the darker regions. By starving them or by feeding on the leaves of the plant they can in the laboratory be made at will to move toward or away from a source of light.

Mechanism of Muscular Movement.—Turning to what we may regard as the other corner of this field, namely, the biochemical investigation of the mechanism of muscular movement in animals we find one of the most complete chapters of modern biochemistry. The long series of researches of outstanding merit by Hopkins and Fletcher, Meyerhof and A. V. Hill have taught us how the glycogen of muscle is broken down to sugar; how the sugar, passing through the intermediate stage of being combined with phosphoric acid, gives rise to the lactic acid that initiates the contraction, and how these anaerobic changes are followed by an oxidative phase of recovery during which part of the lactic acid passes back into its precursor, whilst the remainder is oxidized to carbon dioxide and water. These changes have been followed with such precision by chemical and physical methods that the heat production of the muscle during the whole cycle has been accounted for with considerable exactitude by a knowledge of the heat exchanges of the chemical reactions which are believed to occur. In spite of these carefully compiled results, we are as yet ignorant of the actual processes involved when the muscle fibre shortens in contraction.

Hormones.—The processes of secretion and excretion have been the subject of extensive biochemical research, although mainly on animal tissues. The discovery by Starling and Bayliss of the agents known as hormones (*q.v.*) showed for the first time how important a part such chemical messengers play in the co-ordinating mechanisms of the higher animals. Their discovery of secretin, the substance of, as yet, undetermined nature which is

produced in the mucosa of the upper part of the small intestine under the stimulus of the entry of acid food-material from the stomach, and which, passing into the blood stream, invokes, in a very short space of time, the secretion of the digestive juice of the pancreas, has paved the way for the discovery by Banting and Best of the internal secretion of the pancreas itself, and more recently of that of the internal secretion of the parathyroid gland by Collip. Few more striking examples of the service of chemistry to the study of biological problems concerning human welfare could be given than the discovery of the nature of adrenalin and its synthesis by Takamine, and the isolation of a specific substance of the thyroid gland (thyroxin) by Kendall and the more recent demonstration of the chemical constitution of this remarkable substance and its synthesis by Harington. Viewed as a whole, the regulatory action (*see* ENDOCRINOLOGY) exerted by the secretions of the various glands and tissues of the higher animals is seen to be one of the most delicately balanced nature, but it is one that is quite definitely open to chemical investigation.

Excretory Processes.—The processes of excretion by which living organisms rid their tissues of waste products have, as yet, been scarcely investigated at all in plants. In animals, more particularly in the mammals, they have been extensively examined from the biochemical standpoint. The secretion of urine, the work done by the kidney in this process, the chemical and physico-chemical principles underlying the concentrations of waste products that appear in the excreted fluid, all these have been the subject of prolonged and fruitful investigation.

Secretory Processes.—Of no less interest are problems concerning the secretion by living cells, such as the gastric mucosa of animals, of fluids containing appreciable concentrations of free mineral acids. These questions are intimately bound up with the very general one concerning the mechanisms by which the reaction of the body fluids is maintained within narrow limits. The study of the system of amphoteric colloids and simple electrolytes that constitute the tissue fluids of animal or plant tissues has, from the standpoint of physical chemistry, been almost exhaustive, and the analysis, step by step, of the influence of the many factors playing a rôle in the cycle of changes that occurs in blood during its circulation in the bodies of animals stands as one of the most impressive tributes to the application of the rigid, quantitative methods of modern physical chemistry to problems of outstanding biological importance. Many other spheres of extensive biochemical work might be mentioned, but it will be sufficient if brief reference be made to the chemical investigations of fermentation and bacterial changes.

Fermentation Processes.—To-day, as a result of the researches of Harden and Young in Great Britain, of Fernbach in Paris, and of C. Neuberg in Germany, we are in possession of a reasonably clear idea of the stages by which the sugar molecule is broken down to yield alcohol and carbon dioxide when fermented by yeast. Most of the intermediate products have actually been isolated and their part in the process proven. Of particular interest is the fact that the most recent work on the fermentation of sugar by yeast and on its degradation in the cells of the animal body points to the essential steps in the breakdown of the carbohydrate molecule being the same in both cases.

Probably in no other field of research in biochemistry have so many striking examples been found as in that of fermentation chemistry, of the course of a reaction being changed by alterations in the conditions of the experiment. Certain of these diversions of the normal course of events have proved of considerable economic value, as, for example, when, during the World War, German scientists were able to prepare considerable quantities of glycerol from sugar by causing inhibition of the fermentation at a certain stage by the addition of sulphites.

Apart from the alcoholic fermentations there are numerous other processes, many of them of considerable technical importance, in which the action of the bacteria (*see* BACTERIOLOGY) or other micro-organisms is the subject of biochemical research.

(J. C. D.)

BIOGENESIS, a biological term for the theory according to which each living organism, however simple, arises by a process of budding, fission, spore-formation or sexual reproduction from a parent organism. Under the heading of ABIOTENESIS (*q v.*) is discussed the series of steps by which the modern acceptance of biogenesis and rejection of abiogenesis has been brought about. No biological generalization rests on a wider series of observations, or has been subjected to a more critical scrutiny than that every living organism has come into existence from a living portion or portions of a pre-existing organism. In the articles REPRODUCTION and HEREDITY the details of the relations between parent and offspring are discussed. There remains for treatment here a curious collateral issue of the theory. It is within common observation that parent and offspring are alike: that the new organism resembles that from which it has come into existence. In fine, biogenesis is homogenesis. Every organism takes origin from a parent organism of the same kind. The conception of homogenesis, however, does not imply an absolute similarity between parent and organism. In the first place, the normal life-cycle of plants and animals exhibits what is known as alternation of generations, so that any individual in the chain may resemble its grand-parent and its grand-child, and differ markedly from its parent and child. Next, any organism may pass through a series of free-living larval stages, so that the new organism at first resembles its parent only very remotely, corresponding to an early stage in the life-history of that parent. (*See* EMBRYOLOGY, LARVAL FORMS and REPRODUCTION.) Finally, the conception of homogenesis does not exclude the differences between parent and offspring that continually occur, forming the material for the slow alteration of stocks in the course of evolution (*see* VARIATION and SELECTION). Homogenesis means simply that such organism comes into existence directly from a parent organism of the same race, and hence of the same species, sub-species, genus and so forth.

From time to time there have been observers who have maintained a belief in the opposite theory, to which the name heterogenesis has been given. According to the latter theory, the offspring of a given organism may be utterly different from itself, so that a known animal may give rise to another known animal of a different race, species, genus, or even family, or to a plant, or *vice versa*. The most extreme cases of this belief is the well-known fable of the "barnacle-geese," an illustrated account of which was printed in an early volume of the Royal Society of London. Buds of a particular tree growing near the sea were described as producing barnacles, and these, falling into the water, were supposed to develop into geese. The whole story was an imaginary embroidery of the facts that barnacles attach themselves to submerged timber and that a species of goose is known as the barnacle goose. In modern times the exponents of heterogenesis have limited themselves to cases of microscopic animals and plants, and in most cases the observations that they have brought forward have been explained by minuter observation as cases of parasitism. No serious observer, acquainted with modern microscopic technical methods, has been able to confirm the explanation of their observations given by the few modern believers in heterogenesis.

(P. C. M.)

BIOGRAPHY, that form of history which is applied, not to races or masses of men, but to an individual. The idea of the distinction between biography and history is a modern thing; we speak of "antique biography," but it is doubtful whether any writer of antiquity, even Plutarch, clearly perceived its possible

existence as an independent branch of literature. All of them, and Plutarch certainly, considered the writing of a man's life as an opportunity for celebrating, in his person, certain definite moral qualities. It was in these, and not in the individual characteristics of the man, that his interest as a subject of biography resided.

The true conception of biography, therefore, as the faithful portrait of a soul in its adventures through life, is very modern. We may question whether it existed, save in rare and accidental instances, until the 17th century. The personage described was, in earlier times, treated either from the philosophical or from the historical point of view. In the former case, rhetoric inevitably clouded the definiteness of the picture; the object was to produce a grandiose moral effect, to clothe the subject with all the virtues or with all the vices; to make his career a splendid example or else a solemn warning. The consequence is that we have to piece together unconsidered incidents and the accidental record of features in order to obtain an approximate estimate. We may believe, for instance, that a faithful and unprejudiced study of the emperor Julian, from the life, would be a very different thing from the impression left upon us by the passions of Cyril or of Theodoret. In considering what biography, in its pure sense, ought to be, we must insist on what it is not. It is not a philosophical treatise nor a polemical pamphlet. It is not, even, a portion of the human contemporary chronicle. Broad views are entirely out of place in biography, and there is perhaps no greater literary mistake than to attempt what is called the "Life and Times" of a man. In an adequate record of the "times," the man is bound to sink into insignificance; even a "Life and Times" of Napoleon I. would be an impossible task. It fills its canvas with one figure, and other personages, however great in themselves, must always be subsidiary to the central hero. The only remnant of the old rhetorical purpose of "lives" which clearer modern purpose can afford to retain is the relative light thrown on military or intellectual or social genius by the achievements of the selected subject. Even this must be watched with great care, lest the desire to illuminate that genius, and make it consistent, should lead the biographer to gloss over frailties or obscure irregularities. In the old "lives" of great men, this is precisely what was done. If the facts did not lend themselves to the great initial thesis, so much the worse for them. They must be ignored or falsified, since the whole object of the work was to "teach a lesson," to magnify a certain tendency of conduct. It was very difficult to persuade the literary world that, whatever biography is, it is not an opportunity for panegyric or invective, and the lack of this perception destroys our faith in most of the records of personal life in ancient and mediaeval times. It is impossible to avoid suspecting that Suetonius loaded his canvas with black in order to excite hatred against the Roman emperors; it is still more difficult to accept more than one page in three of the stories of the professional hagiographers. As long as it was a pious merit to deform the truth, biography could not hope to flourish.

Among the ancients, biography was not specifically cultivated until comparatively later times. The lost "Lives" of Critias were probably political pamphlets. We meet first with deliberate biography in Xenophon's memoirs of Socrates, a work of epoch-making value. Towards the close of the 1st century, Plutarch wrote one of the most fascinating books in the world's literature, his *Parallel Lives* of 46 Greeks and Romans. In later Greek, the *Life of Apollonius of Tyana* was written by Philostratus, who also produced *Lives of the Sophists*. In the 3rd century, Diogenes Laertius compiled a *Lives of the Philosophers*, which is of greater interest than a *Lives of the Sophists* composed 100 years later by Eunapius. Finally in the 10th century, Suidas added a biographical section to his celebrated *Lexicon*. In Latin literature, the earliest biography we meet with is the fragment of the *Illustrious Men* of Cornelius Nepos. Memoirs began to be largely written at the close of the Augustan age, but these, like the *Life of Alexander the Great*, by Q. Curtius Rufus, were rather historical than biographical. Tacitus composed a life of his father-in-law, Agricola; this is a work of the most elegant and stately beauty. Suetonius was the author of several biographical com-

pilations, of which the *Lives of the Twelve Caesars* is the best known; this was produced in the year 120. Marius Maximus, in the 4th century, continued the series of emperors down to Heliogabalus, but his work has not been preserved. The *Augustan History*, finished under Constantine, takes its place, and was concluded and edited by Flavius Vopiscus.

English Biographies.—Biography hardly begins to exist in English literature until the close of the reign of Henry VIII. William Roper (1496–1578) wrote a touching life of his father-in-law, Sir Thomas More, and George Cavendish (1500–61?), a memoir of Cardinal Wolsey which is a masterpiece of liveliness and grace. It is with these two works, both of which remained in manuscript until the 17th century, that biography in England begins. The lives of English writers compiled by John Bale (1495–1563) are much more primitive and slight. John Leland (d. 1552) and John Pits (1560–1616) were antiquaries who affected a species of biography. In the early part of the 17th century, the absence of the habit of memoir writing extremely impoverishes our knowledge of the illustrious authors of the age, of none of whom are there preserved such records as our curiosity would delight in. The absence of any such chronicle was felt, and two writers, Thomas Heywood and Sir Aston Cokayne, proposed to write lives of the poets of their time. Unfortunately they never carried their plans into execution. The pioneer of deliberate English biography was Izaak Walton, who in 1640, published a *Life of Donne*, followed in 1651 by that of *Sir Henry Wotton*, in 1665 by that of *Richard Hooker*, in 1670 by that of *George Herbert*, and in 1678 by that of *Dr. Robert Sanderson*. These five reprinted, under the title of *Walton's Lives*, were not only charming in themselves, but the forerunners of a whole class of English literature. Meanwhile, Fuller was preparing his *History of the Worthies of England*, which appeared after his death, in 1662, and John Aubrey (1626–97) was compiling his *Minutes of Lives*, which show such a perfect comprehension of the personal element that should underlie biography; these have only in our own days been completely given to the public. Edward, Lord Herbert of Cherbury (1583–1648), wrote a brilliant autobiography, first printed in 1764; that of Anne Harrison, Lady Fanshawe (1625–1680), remained unknown until 1829. A very curious essay in biography is the memoir of Colonel John Hutchinson, written by his widow, Lucy, between 1664 and 1671. Margaret Lucas, duchess of Newcastle (1624?–74), wrote her own life (1656) and that of her duke (1667). The *Athenae Oxonienses* of Anthony à Wood (1632–95) was a complicated celebration of the wit, wisdom and learning of Oxford notabilities since the Reformation. In 1668 Thomas Sprat (1635–1713) wrote a *Life of Cowley*, which was very much admired and which exercised for many years a baneful influence on British biography. Sprat considered that all familiar anecdote and picturesque detail should be omitted in the composition of a memoir, and that moral effect and a solemn vagueness should be aimed at. The celebrated funeral orations of Jeremy Taylor were of the same order of eloquence, and the wind of those grandiose compositions destroyed the young shoot of genuine and simple biography which had budded in Walton and Aubrey.

From this time forth, for more than half a century, English biography became a highly artificial and rhetorical thing, lacking all the salient features of honest portraiture. William Oldys (1696–1761) was the first to speak out boldly; in 1747, in the preface to the *Biographia Britannica*, he pointed out "the cruelty, we might even say the impiety, of sacrificing the glory of great characters to trivial circumstances and mere convenience," and attacked the timid and scrupulous superficiality of those who undertook to write lives of eminent men, while omitting everything which gave definition to the portrait. In 1753 the *Lives of the Poets*, which bore the name of Theophilus Cibber (1703–58), but was mainly written by Robert Shiels (d. 1753), gave a great deal of valuable information with regard to the personal adventures of our writers. Dr. Johnson's *Life of Savage* (1744), though containing some passages of extreme interest, was a work of imperfect form, but Mason's *Life and Letters of Gray* (1774) marks a great advance in the art of biography. This was the earliest

memoir in which correspondence of a familiar kind was used to illustrate and to expand the narrative, and Mason's *Gray* is really the pioneer of almost all modern English biography. For the first time it was now admitted that letters to intimate friends, not written with a view to publication, might be used with advantage to illustrate the real character of the writer. Boswell, it is certain, availed himself of Mason's example, while improving upon it, and in 1791 he published his *Life of Dr. Samuel Johnson*, which is the most interesting example of biography existing in English or perhaps in any language.

As soon as the model of Boswell became familiar to biographers it could no longer be said that any secret in the art was left unknown to them, and the biographies of the 19th century are all more or less founded upon the magnificent type of the *Life of Johnson*. But few have even approached it in courage, picturesqueness or mastery of portraiture. In the next generation Southey's lives of *Nelson* (1813) and *John Wesley* (1820) at once became classics; but the pre-eminent specimen of early 19th century biography is Lockhart's superb *Life of Sir Walter Scott* (1837-38). The biographies of the 19th century are far too numerous to be mentioned here in detail; in the various articles dedicated to particular men and women in this Encyclopædia, the date and authorship of the authoritative life of each person will in most cases to be found appended.

Other Countries.—To Switzerland appears due the honour of having given birth to the earliest biographical dictionary ever compiled, the *Bibliotheca Universalis* of Konrad Gesner (1516-65), published at Zürich in Latin, Greek and Hebrew, from 1545 to 1549. A very rare work, by a writer of the greatest obscurity, the *Prosopographia* of Verdier de Vauprivas, published at Lyons in 1573, professed to deal with the lives of all illustrious persons who had flourished since the beginning of the world.

In mediaeval and Renaissance France there existed numerous memoirs and histories, such as those of Brantôme, into which the lives of great men were inserted, and in which a biographical character was given to studies of virtue and valour, or of the reverse. But the honour of being the earliest deliberate contribution to biography is generally given to the *Acta Sanctorum*, compiled by the Bollandists, the first volume of which appeared in 1653. It was confined to the lives of saints and martyrs, but in 1674 Louis Moréri, in his *Grand Dictionnaire*, included a biographical section of a general character. But the earliest biographical dictionary which had anything of a modern form was the celebrated *Dictionnaire historique et critique* of Pierre Bayle, in 1696; the lives in this great work, however, are too often used as mere excuses for developing the philosophical and controversial views of the author; they are nevertheless the result of genuine research and have a true biographical value.

In Italian literature, biography does not take a prominent place until the 15th century. The *Lives of Illustrious Florentines*, in which a valuable memoir of Dante occurs, was written in Latin by Filippo Villani. Vespasiano da Bisticci (1421-98) compiled a set of biographies of his contemporaries, which are excellent of their kind. The so-called *Life of Castruccio Castracani*, by Machiavelli, is hardly a biography, but a brilliant essay on the ideals of statecraft. Paolo Giovio (1483-1552) wrote the lives of poets and soldiers whom he had known. All these attempts, however, seem insignificant by the side of the autobiography of Benvenuto Cellini (1501-71), confessedly one of the most entertaining works of the world's literature. A great deal of biography is scattered throughout the historical compilations of the Italian Renaissance, and the *Lives of the Artists*, by Giorgio Vasari (1512-74), is a storehouse of anecdotes admirably told. We find nothing else that requires special mention till we reach the memoir-writers of the 18th century, with the autobiographies of Count Carlo Gozzi and Alfieri; and on the whole, Italy, although adopting in the 19th century the habit of biography, has rarely excelled in it.

In Spanish literature Fernán Pérez de Guzmán (1378-1460), with great originality, enshrined, in his *Generations and Likenesses*, a series of admirable literary portraits; he has been called the Plutarch of Spain. But, in spite of numerous lives of saints, poets and soldiers, Spanish literature has not excelled in bio-

graphy, nor has it produced a single work of this class which is universally read. In Germany there is little to record before the close of the 18th century.

In the course of the 19th century a new thing in biography was invented, in the shape of dictionaries of national biography. Of these, the first which was carried to a successful conclusion was the Swedish (1835-57), which occupied 23 volumes. This dictionary was followed by the Dutch (1852-78), in 24 volumes; the Austrian (1856-91), in 35 volumes; the Belgian (which was begun in 1866); the German (1875-1900), in 45 volumes; and others, representing nearly all the countries of Europe. England was behind the competitors named above, but when she joined the ranks a work was produced the value of which can hardly be exaggerated. The project was started in 1882 by the publisher George Smith (1824-1901), who consulted Leslie Stephen. The first volume of the *English Dictionary of National Biography* was published on Jan. 1, 1885, under Stephen's editorship. A volume was published quarterly, with complete punctuality until midsummer 1900, when vol. 63 closed the work, which was presently extended by the issue of supplementary volumes. In May 1891 Leslie Stephen resigned the editorship and was succeeded by Sidney Lee, who edited the work with its supplementary volumes till 1916, when it was transferred to the Oxford University Press. A further supplementary volume containing the biographies of those who had died between 1912 and 1921 was published in 1927 under the editorship of H. W. C. Davis and J. R. H. Weaver. The *Dictionary of National Biography* contains the lives of between 30,000 and 40,000 persons. (E. G.)

MODERN DEVELOPMENTS

Biography is a branch of literature; that is to say, it is an art, not a science. The biographies that succeed are those that people are always ready to read for the kind of pleasure given by literary art. The biographies that fail are those that do not give that pleasure. It is necessary to affirm these elementary truths, because the present age, weak in creative energy, tends to exalt the merely explanatory or sceptical activities, and shows a desire to claim that biography is a branch of science or a department of morbid psychology. That an art is promoted by being called a science is a superstition of persons, often very learned, who possess apparatus, but lack creative vigour.

We must beware, therefore, of those who confuse a plain case by the introduction of misleading qualifications. No biographer can claim merit by urging that his work is in some special sense "new" or "modern." A "new" or "modern" biography can only mean a "recent" biography. If a youthful iconoclast writes a hostile life of Scott as a counterblast to Lockhart, the *differentia* of his book will be hostility, not novelty or modernity. Nor will the hostility be necessarily a merit or a defect. A hostile biography, like any other, must justify itself by success, that is, by giving pleasure to generations of readers. Actually, a perverse biography that tries to belittle some large figure (e.g., Dickens) is as unlikely to succeed as the inverse biography that tries to magnify a minor figure (e.g., George IV.).

The Descent from Johnson.—The publication in 1918 of *Eminent Victorians* by Giles Lytton Strachey gave some encouragement to those who fail to distinguish between malice and veracity. Though generally labelled "new" and "modern," it descends in a direct line from the work of the greatest of English biographers, himself, by singular coincidence, the subject of the greatest of English biographies (see JOHNSON; BOSWELL). The opening lines of Johnson's *Life of Cowley* are so cogent that no excuse need be made for quoting them.

The *Life of Cowley*, notwithstanding the penury of English biography, has been written by Dr. Sprat; . . . but his zeal of friendship, or ambition of eloquence, has produced a funeral oration rather than a history: he has given the character, not the life of Cowley; for he writes with so little detail, that scarcely anything is distinctly known, but all is shown confused and enlarged through the mist of panegyric.

The first sentences of the actual *Life* read thus:

Abraham Cowley was born in the year one thousand six hundred and eighteen. His father was a grocer, whose condition Dr. Sprat conceals under the general appellation of a citizen.

By "character" Johnson means something like the Theophrastian "character" (see THEOPHRASTUS) which was vastly popular in England during the 17th century—the description of supposed types, such as the abstract "just man," "avaricious man," and so forth, instead of real individuals. The "character" always tends to become a model or vehicle of insincerity or hypocrisy, that is, of suppression and pretence. The father of a "character" is never a grocer, but a citizen. Hypocrisy was the moral and intellectual habit of so many vigorously respectable people during the Victorian and Albertine age that the "character" biography became a natural expectation. The admission of human weakness or natural frailty was resented as if it were a malicious perversion of the truth. Thus, the *Memoirs* (1851) of his famous uncle, by Bishop Christopher Wordsworth (q.v.), suppressed certain vital incidents of the poet's early life as being out of the "character." Thus, too, the terribly competent and imperious Florence Nightingale, the rightly unscrupulous organizer of victory in a sacrificed region of warfare, had to be presented to sentimental complacency as the exquisite "Lady with the Lamp," the scarcely earthly ministering angel. Now any representation of Florence Nightingale as a delicate, docile lady in the dove-like raiment of "the Nurse," is not only a misrepresentation of the facts, but a positive insult to her remarkable achievement. It is the Theophrastian "character" run mad.

Lytton Strachey's Method.—When Strachey rejected the type and regarded the person, he invented nothing new in method; he went back to Johnson, who biographically allowed a person to have a human grocer, instead of a Theophrastian "citizen," as father. Strachey took four Victorian figures, whom the methods of the funeral oration or its later substitute, journalistic panegyric, had turned into images of impeccable eminence and he described them, not as "characters," but as human beings. His types were Dr. Arnold (Public School Tradition), General Gordon (the Christian Soldier), Florence Nightingale (the Angel of Mercy) and Cardinal Manning (the Sainly Prelate). These eminent Victorians he treated as frankly as Johnson had treated his eminent Carolines and Jacobean. The images came alive under the process. In *Queen Victoria* (1921) Strachey applied the same methods to an august figure so grossly magnified into inhuman dimensions that William Nicholson's excellent woodcut of her as a little but firmly posed old lady in a bonnet had, a few years before, been hotly resented as an insult to majesty. The ideal of royal portraiture—the Winterhalter tradition brought down to date—was Stuart-Wortley's representation of Edward VII. as an immensely tall and magnificently overpowering figure in Court dress. It bore no resemblance whatever to that popular and public monarch. It was a Theophrastian "king"; and any footman from Buckingham Palace might have been the model. Biographers were expected to conform to this tradition of distortion. It is the special merit of Strachey that he did not conform, but went back to the nobler example of Johnson. There are other famous Victorians, George Eliot for instance, who would clearly gain by frankly human treatment. Those who think that by turning "characters" into human beings Strachey has diminished his subjects understand neither life nor letters. For them the practice of successful "modern" biography consists in finding eminent persons to belittle or little persons to magnify. It is now possible to find studies in biography, specifically described as "new" or "modern," which contain nothing but the impertinence of youth to maturity or the obtuseness of stupidity to achievement.

Partial Portraits.—There is no formula for the biographer. Like the poet and the novelist, like the painter and the sculptor, he must be true to his medium, but he is as free as they to seek individual form and expression. It would be intolerable if all biographies were written to the model of Boswell's *Johnson* or Lockhart's *Scott*. A chapter of a life may be better than the whole! A special episode, treated artistically, may reveal more than a protracted narrative. Two excellent examples of such "partial portraits" are *Father and Son* (1907), by Sir Edmund Gosse (q.v.), and *Byron, the Last Journey* (1924), by Harold Nicolson. The first, originally published anonymously, is the story not merely of the clash between two temperaments, but of the strife

between two generations. A long story could tell no more and might even tell less. Nicolson's unexcited account of one year, and that the last in Byron's life, presents a figure which is not only more real and intelligible, but actually more romantic than the romances. It views Byron from the latter end and is a fully successful essay in retrospective biography.

The frank casting of biographical material into the form of a novel may be felicitous when the subject is Shelley and the writer André Maurois (*Ariel*, 1923). On the other hand, the sedulous denigration of Dickens in a novel *This Side Idolatry* by C. Bechhofer Roberts (1928) is offensive, not for moral reasons, but because the representation, however supported by evidence, is irrelevant. There is no law in the matter. Biographical fiction can hardly be forbidden when historical fiction is allowed. A novelist has at least as much right as a dramatist to the life of Abraham Lincoln. In *Venetia* Disraeli succeeded in transmitting much of Byron, but failed to transmit anything of Shelley, as Peacock had failed before him, in the caricature of *Nightmare Abbey*. Some of Disraeli's other "real" characters in fiction are admirable, e.g., the sketch of Palmerston as Lord Roehampton in *Endymion*. The life of Disraeli himself by André Maurois (1927) tells a story as fascinating as a novel, without departing from the normal frame-work of a biography. Other successful examples of what may be called essential biography are the *Parnell* of St. John Ervine (1925) and the *Palmerston* of Philip Guedalla (1926). Brilliant and personal as the latter is, it rests upon a solid foundation of research. To say that the *Kaiser Wilhelm II.*, the *Napoleon* and the *Bismarck* of Emil Ludwig are "film-biographies" is not in the least to disparage them, for there are excellent as well as execrable films. Of these three the *Bismarck* is the most satisfying, but not the most attractive; for though the author triumphs over his material, the subject itself lacks spectacular appeal. The qualities that made Emil Ludwig successful as the biographer of Napoleon or the Kaiser disable him utterly when he attempts a life of Jesus.

The Chronicle-biography.—In the realm of biography there is always place for the work that is not so much a creation as a chronicle; that is to say, for the work that is a careful assembly of material by someone in possession of the facts. Many recent political and official biographies belong to the category of chronicle and do not need discussion as works of biographical art. A rather special case of the chronicle-biography is the *Life of Samuel Butler* (1919), by Henry Festing Jones, who had already proved his biographical skill in the compilation of a short, vivid sketch of the strange person with whom he had been closely associated. It is idle to say that no one wants such a long biography of such a minor literary figure; for the answer is first, that people who like Butler like him enough to want to know as much as possible about him, and next, that the sole possessor of information is fulfilling a very proper duty in recording it.

An even more remarkable instance of the devotion which is expended upon the collection and recording of personal detail is the *Life of Beethoven*, by William Alexander Thayer, for here the biographer pursues the man so earnestly that he overlooks the musician, who, after all, is what matters most.

There is, as we have said, no formula for biography; there is only the pragmatic test of success. Even the standard "life" in two volumes need not be, though it often has been, an expanded epitaph in the lapidary style of the monumental mason. What the best biographical writing of recent times can truthfully claim is that it has turned wholesomely away from the falsified "character" and the exaggerated "funeral oration," and has tried to depict human beings instead of frigid types "shown confused and enlarged through the mist of panegyric." As examples of modern biographical activity we may mention that the *Dictionary of National Biography* continues its career of plain usefulness and that the classic series called *English Men of Letters* has entered upon a third and less classic phase of its welcome existence.

(G. SN.)

The United States.—In the United States biography apart from history was comparatively late in developing. Historical chroniclers such as John Smith founded certain long-lived indi-

vidual legends, for example the Pocahontas story, or gave vivid thumb-nail sketches of their more prominent contemporaries as did Capt. Edward Johnson (1599-1672) in his *Wonder-Working Providence of Zion's Saviour in New England* (1654).

We do find extended biographical work, however, in that curious jumble of fact, tradition and personal prejudice—Cotton Mather's *Magnalia Christi Americana* (1702), in which are sections devoted to the lives of the governors and names of the magistrates "that have been shields to the churches of New England," to famous ministers and to the history of Harvard college and of "some eminent persons therein educated." Nevertheless in spite of such spirited bits of narrative—as Sir William Phips' finding of long buried Spanish treasure under the sea, the pompous style and moralizing treatment have on the whole won deserved oblivion. Almost complete oblivion has also overtaken the single biographies produced in the colonial epoch—*Parentator* (1724), the quaint tribute to Increase Mather by his more famous son; *The Life and Character of the Reverend Benjamin Colman, D.D.* (1749) by his son-in-law, 'Ebenezer Turell, one of the most unassuming and appealing of the group; and Jonathan Edwards' life of David Brainerd (1749), a young missionary who died of consumption.

During the Revolution writers and thinkers were too occupied with waging war on live questions to extol the virtues and accomplishments of dead dignitaries. What few semi-biographical notes were struck were satirical—thinly veiled allusions to prominent members of the opposite party such as are found in Mercy Otis Warren's farce *The Group* (1775)—or incidental—the acrid sketches in her *History of the American Revolution* (1805). After the Revolution, however, emphasis shifted from the divines who had absorbed the attention of writers to the great patriotic figures who were already assuming heroic proportions. *The Life of Washington* (1800) by Parson Weems, a versatile and somewhat unscrupulous man, although it was regarded askance even by contemporary scholars, proved one of the best-selling biographies ever written in America and imbedded in the popular mind fictions like the hatchet story which have not yet been wholly uprooted. Also inaccurate was the *Life of Patrick Henry* (1817) by William Wirt (1772-1834), lawyer and essayist, whose polished style makes the book more readable, however, than the *Life of James Otis* (1823) by William Tudor (1779-1830) or the ponderous *Life of Washington* (1804-07) by Chief Justice John Marshall.

One of the first tributes to American writers was the somewhat stilted and inaccurate *Life of Charles Brockden Brown* (1815) by William Dunlap (1766-1839), playwright, manager, so-called "Father of the American Theatre." Edgar Allan Poe indulged in literary chit-chat in his *Literati of New York City* (1846), and his own literary executor, Rufus Griswold (1815-57) by his distorted memoir of the poet (1849) gave one of the most prominent examples of the satisfaction of personal grudges which for a period blackened American biography. The best biographical work which came out of New York at that time (and probably the best biographical work in America to date) was the Spanish series of Irving and his last work *The Life of Washington* (1855-59). The opportunities he had to examine Spanish source materials and to imbibe the atmosphere of the places about which he wrote as well as the suavity of his style and the general picturesqueness of his theme and treatment caused his *History of the Life and Voyages of Christopher Columbus* (1828), according to Southey, to place him "in the front rank of modern biographers" and to secure him, according to Edward Everett, the position "of founder of the American school of polite learning."

Although Cooper took time off from his fiction to write *Lives of Distinguished American Naval Officers* (1842-45) and *Ned Myers* (1843), the life of a common sailor who had been with him on the "Sterling," and although his Leatherstocking series wielded an extraordinary influence on most of the later scout biographies, for work of a sort to compare with Irving we must turn to the New England school. There Jared Sparks, for a time editor of the *North American Review*, professor of history and later president of Harvard, not only wrote numerous biographies himself but edited the most extensive work of its nature to date,

American Biography, which appeared in two series (25 vol., 1834-38 and 1844-47) and which still has value. The literary contacts of Boston, Cambridge and Concord through the latter part of the 19th century brought forth numerous biographies on a comparatively high level. Emerson's tribute to Thoreau (1862), Charles Eliot Norton's biographies and editions of the literary remains of his various friends, the work of Thomas Wentworth Higginson, O. W. Holmes' biographies of Emerson (1885) and Motley (1879), the memoirs of the Transcendentalists, although they have their blemishes, are generally satisfactory. About the same time in the South John Pendleton Kennedy (1795-1870), lawyer, politician, essayist and novelist in his *Memoirs of the Life of William Wirt* (1849) carried on the biographical tradition; and the prolific Simms turned off lives of Francis Marion (1844), John Smith (1846) and Nathanael Greene (1849). In the West Timothy Flint by his biography of Boone (1833) and Benjamin Drake by that of Black Hawk (1838) established the biographical tradition of the Frontier.

By the third quarter of the 19th century, then, biography had become well established as a popular form in the United States, and works of this nature issued from the publishers in ever-increasing volume. It is possible only to indicate the chief of the lines of development, many of the outstanding biographies being named in the bibliographies of the individuals whom they concern. One rather common type was the so-called "family biography" in which the children or near relatives of an individual, having free access to his or her papers and intimate knowledge, present their impressions. Of such a nature were biographies of Harriet Beecher Stowe, of Hawthorne, of Julia Ward Howe, of Emily Dickinson and many others. Horace Traubel's devotion to Whitman resulting in *With Walt Whitman in Camden* (1906 *et seq*) furnishes perhaps the best example of the Boswell type of biography. The secretaries of Lincoln, John Hay (1838-1905) and John G. Nicolay (1832-1901) produced in their life of the president (1890) what is not only one of the most comprehensive of American biographies but a book which serves as a history of an epoch. This same use of history on a smaller scale to serve as the background of a central figure is found in W. P. Trent's biography of William Gilmore Simms (1892). A specialized type of biography, the campaign biography written to serve an immediate end—exalting a candidate—has numbered in its ranks no lesser figures than Nathaniel Hawthorne and William Dean Howells.

At the end of the 19th and beginning of the 20th centuries, with the exception of accounts based on personal association, biography fell largely to the lot of the professional editor, the studious minister, the college professor and the aspirants for doctoral honours. Their work had the merit of being almost without exception more accurate than that of the earlier annalists, and while at its worst it was dry and over-pedantic, it was as a rule well written and thorough. Among the best examples of this type of work is the American Men of Letters series edited by Charles Dudley Warner, the biographies of Horace E. Scudder (1838-1902), of M. A. De Wolfe Howe (1864-) and of William Roscoe Thayer (1859-1923).

In the 20th century the broad and even path that the American biographer was complacently treading, however, suddenly branched off at strange tangents. The scholar, the dignified editor of the old school, was jostled by novelists, poets, short-story writers, psychoanalysts, bent on probing the dark recesses of the soul. Lucky are the buried notables who escape without being proved victims of one complex or phobia, and lucky are the descendants who need fear the revelation of no family skeletons. For the so-called "new biography" like the realism of the Zola school does not believe in reticences; sometimes it seems almost to glory in pillorying the past. The chatty, personal, vivid note popularized in biography by Strachey in England, Ludwig in Germany, André Maurois in France, and Gamaliel Bradford (1863-) in America, commendable in itself, has given rise in some cases to serious abuses. Spice has been sought to the neglect of truth; a biographer, intent on dragging from his pedestal an over-idealized hero or on playing up a side of his subject that has been neglected or glossed over is

apt to forget his sense of proportion, to stress that side to the exclusion of all others, and sometimes, unconsciously perhaps, to twist the evidence.

In spite of these abuses, however, the advantages of the new biography are many. Written usually with a sense of climax and an admirable dramatic quality, these books have made vastly more vital and interesting the people they portray; they have increased the reading public devoted to this genre; they have done good service in insisting upon the truth without fear or favour. No one now need come to the reading of biography as to a task; Carl Sandburg's *Abraham Lincoln, the Prairie Years* (1926) is the work of a poet and mystic profoundly in sympathy with his subject; Cameron Rogers' *The Magnificent Idler* (1926) makes Walt Whitman almost a hero of romance; *Emerson* (1927) by Van Wyck Brooks (1886—), re-creates in vivid, staccato fashion the Concord sage's life and environment.

At the present time the outlook for American biography seems bright. Under the pioneer leadership of Ambrose W. Vernon (1870—) courses in biography are being given in some American colleges. The interest in social history has drawn attention to many representative figures hitherto neglected; the State historical societies are preserving records of the more significant local personages; and *The Dictionary of American Biography*, financed by Adolph Ochs of the *New York Times*, promises to be the most complete and correct collection of American biography yet published. (D. A. D.)

BIOLOGICAL AND ZOOLOGICAL ARTICLES. The main branches of biological science are dealt with in special articles such as ZOOLOGY, EMBRYOLOGY and PALAEONTOLOGY. BIOLOGY itself is treated in an article outlining the scope and applications and history of the science. In addition to the big article on EVOLUTION, there are separate articles on such branches as SEXUAL SELECTION, NATURAL SELECTION, EVOLUTION AND MIND and ACCLIMATIZATION; further, the evolutionary aspect has been stressed in many of the articles dealing with the various groups of animals, e.g., MAMMALIA and AMPHIBIA, and in other general articles such as ZOOLOGICAL REGIONS, DISTRIBUTION OF ANIMALS, MIMICRY and so on. HEREDITY is the central article of another group which includes such subjects as LAMARCKISM, CYTOLOGY, SEX, REPRODUCTION and MUTATION. Each of the large groups of animals has an article devoted to it, e.g., CRUSTACEA, PROTOZOA, MOLLUSCA, INSECTS and REPTILES; in mammals, besides a comprehensive account of the class as a whole in the article MAMMALIA, each order has an article devoted to it, among which PRIMATES, CETACEA, CARNIVORA and PROBOSCIDEA may be mentioned as examples, and the principal animals are fully covered by a series of shorter articles devoted more especially to their natural history—DEER, ANTELOPE, DOG, FOX, LION, CHIMPANZEE, ELEPHANT, HORSE, KANGAROO, etc. Birds are treated in the general articles BIRD and ORNITHOLOGY, the latter article including a section on the economic status of birds; there are, in addition, numerous shorter articles on individual birds, e.g., DODO, CUCKOO, EAGLE, FALCON, HERON, HUMMING BIRD, BIRD OF PARADISE, THRUSH, SPARROW, etc. Insects are covered by comprehensive articles on INSECTS and ENTOMOLOGY, in the latter of which is an account of the economic bearings of this important class; the better known and economically important insects are dealt with in greater detail in separate articles, such as GYPSY MOTH, APHIDES, MANTIS, GRASSHOPPER, MAY-FLY and PHYLLOXERA, as well as in articles on the more important orders:—LEPIDOPTERA, DIPTERA, ORTHOPTERA, etc. Ants, bees and wasps, in addition to treatment under these headings and in the article HYMENOPTERA, are considered at length, with the termites, in their social aspects in the article SOCIAL INSECTS. The other groups of animals are similarly covered: thus there is a general article REPTILES, with shorter articles such as SNAKE, CROCODILE, DINOSAURIA, LIZARD, GECKO, etc.; a general article FISHES, with subsidiaries such as FISHERIES, HERRING, COD, SALMON, EEL, SHARK, etc.; a general article CRUSTACEA, with supplementary articles on the important subdivisions, COPEPODA, MALACOSTRACA, etc., and on such important forms as CRAB, LOBSTER, SHRIMP, WOOD-LOUSE and others. The better known fossil animals are also given separate

articles, e.g., DINOSAURIA, TRILOBITES, ICHTHEYOSAURUS, GRAPTOLITES, ARCHAEOPTERYX, TITANOTHERIA. The various methods of protecting animals and preserving wild life are covered by such articles as PROTECTION OF ANIMALS, PROTECTION OF BIRDS, NATURE RESERVES, BIRD SANCTUARIES and GAME RESERVES; on this aspect, too, the article BIOLOGICAL SURVEY has an important section, while ZOOLOGICAL GARDENS, AQUARIUM and AVIARY deal with animals in captivity. The great advance in the more detailed knowledge of the cells and tissues of the animal body of recent years is summarized in CYTOLOGY, REGENERATION IN ANIMALS, EXPERIMENTAL EMBRYOLOGY and PHYSIOLOGY COMPARATIVE, and kindred articles. Animal psychology and behaviour, which has also received much attention recently, is covered by the general articles COMPARATIVE PSYCHOLOGY and ANIMAL BEHAVIOUR, while SENSES OF ANIMALS, COURTSHIP OF ANIMALS, PLAY OF ANIMALS, EDUCATION IN ANIMALS and other articles deal with special points. Such important groups as PROTOZOA and TAPEWORMS are treated at length and their relations to man clearly brought out, while much of the information is summarized and its main bearings pointed out in the articles PARASITOLOGY and PARASITISM. Finally the application of biological knowledge to man's problems is considered in such articles as MARINE BIOLOGY, ENTOMOLOGY and EUGENICS.

BIOLOGICAL SURVEY. The Biological Survey is one of the eleven bureaus among which are distributed the various lines of research and most of the allied activities of the United States Department of Agriculture. Its functions are investigations for the classification, conservation, utilization, and control of the wild life of the country, the administration of Federal laws for the protection of migratory birds and the prevention of illegal interstate commerce in game and furs, and foreign importations of harmful wild birds and mammals. Federal bird and large-game reservations distributed from the Atlantic to the Pacific and in Alaska, Porto Rico, and the Hawaiian islands are under its administration. The term "wild life" as used here comprises all the vertebrates, except the fishes.

The research work of the bureau includes the technical study of the thousands of species making up the wild life of the United States and adjacent regions, with investigations of their habits, distribution, and economic relations. The responsibilities of the bureau require also its active participation in the conservation and increase of the useful and harmless species and the control or destruction of those economically injurious. These present many difficult problems, which involve the interest of the people of the entire country to an extent not commonly realized.

On July 1, 1886, wild-life research was first established as a distinct unit in the Department of Agriculture, with three employees and an annual appropriation from Congress of \$5,000. At that time the work undertaken was the study of the migration of American birds and the distribution and food habits of the birds and mammals. On July 1, 1927, the number of employees in the Biological Survey exceeded 1,300, and the appropriation made available by Congress for its operations during the year amounted to \$1,346,955. In addition, co-operative funds, mainly to be expended in field work for the control of injurious mammals under the direction of the bureau, amounting to more than \$1,000,000, were contributed by the various States.

Owing to the numbers of birds—estimated to exceed 4,000,000,000 in the United States—their importance to man as game and as destroyers of noxious insects on a gigantic scale, and because of their attractiveness in form, colour and notes, they may be listed as of first importance in our wild life resources. The mammals, however, including both game and fur-bearers, make a close second. What has been accomplished in building up wild-life resources in certain States proves that with a nation-wide exercise of wise conservation, these resources might be increased.

As against the benefits derived from the useful species, man suffers heavy annual losses from various destructive forms of wild life. The pests fall into two groups: firstly, the predatory animals, such as the wolf, coyote, puma, lynx, and a few others, which kill domestic animals; and secondly, the rodents, of which the house rat, prairie dog, various species of ground squirrel,

pocket gopher, hare, and rabbit, which destroy the farmers' products in field and granary, are the most harmful. Both the predatory animals, and the rodents are most numerous in the more thinly populated parts of the country west of the Mississippi. The house rat, however, the most destructive of all, is practically everywhere. The losses through predatory animals in the United States have been estimated to be more than \$20,000,000 annually. Investigations by the Biological Survey indicate an approximated annual loss by house rats of \$200,000,000. The annual losses from all other rodent pests have been estimated as about \$300,000,000. Nearly half the total appropriations for the bureau and all the co-operative funds made available by the States for its operations are for the purpose of controlling these losses.

Control Methods.—Until the survey began the work, sporadic, costly, ineffective efforts were made to subdue the wild bird and mammal pests. The usual method was through the payment of a fixed bounty for the scalp or other part of the offender. Many millions of dollars were thus wasted, and no general relief was obtained. The depredations of animal pests continued and had become so serious by 1916 that, coupled with a great outbreak of rabies carried into five States by coyotes and other predatory animals, the Biological Survey was given the task of controlling the situation, especially in the States west of the Mississippi river, where much of the land still belongs to the Federal Government.

The methods of control of the pests developed by the Biological Survey were soon found to be effective. As a result, States throughout the country have joined forces and are making the campaigns of control joint efforts by the Federal and State governments. Under unified direction by the Biological Survey, these losses have been practically eliminated over considerable areas.

Since 1916, when the control of wild animal pests became the major single activity of the bureau, the kill among the larger predatory animals has been as follows: Wolves, 6,233; coyotes (prairie wolves), more than 500,000; pumas, 1,877. To accomplish this requires the directed efforts of from 250 to nearly 600 hunters each year, the number varying with the season. They use poison, traps, and the rifle.

In the control of the rodent pests, which exist in great numbers over a vast territory, the usual method is to poison them. With the co-operation of farmers and other landowners, poison has been placed over many millions of acres of farming and grazing land and a great reduction made in the abundance of these pests. In considerable areas the prairie dog has been exterminated.

Since 1920 the Biological Survey has been charged with the investigation of the reindeer industry in Alaska, and the development of scientific methods for its improvement and up-building. Between 1892 and 1902 a total of 1,280 reindeer were brought to Alaska by the Bureau of Education from eastern Siberia, and in 1927 they had increased to more than 500,000 in addition to over 150,000 that had been killed for their meat and hides.

Enforcement of Federal game laws has also become part of the work of the bureau. Most far-reaching of these is the Act to enforce the provisions of the Migratory Bird Treaty with Great Britain for the protection of the migratory birds that live part of their lives in the United States and part in Canada. Another law is the Lacey Act to prevent the illegal interstate traffic in game and furs, and controlling the importation of living wild birds and mammals, to prevent the introduction of injurious species. The Survey co-operates with the Alaska Game Commission in the enforcement of the Alaska game and fur laws, and its chief representative in Alaska serves as executive officer of the commission.

All the varied activities of the Biological Survey are based on the scientific research of its staff of naturalists and other trained men. Their field investigations during many years have accumulated a great store of information concerning the distribution and habits of the wild mammals and birds of North America, and have amassed a study collection containing about 60,000 birds and 137,000 mammals.

A continual effort is made through the press and by popular articles to inform the public in regard to the value of useful wild life, the conditions affecting it, and the needs of conservation, in order that it may be maintained. The contributions by the bureau to these subjects are published in the departmental series of bulletins and circulars and in a technical series known as "North American Fauna," the latest of which is numbered 50. These technical reports consist of monographic revisions of groups of mammals, reports on the results of life-zone surveys of State and other major areas, and other technical matter relating to the wild life of the continent.

These publications, the data in the files, and the reference collections constitute the largest store of information available on the wild life of any continent, and make the Biological Survey, with its staff of scientific naturalists, the main centre of information concerning the conservation, utilization, and control of the wild life of North America. The information amassed is being increasingly consulted by wild-life administrators and naturalists in the U.S.A. and abroad, and is of especial use to State game commissions and other organizations in problems constantly arising locally, but requiring for their solution the nation-wide experience of the Biological Survey.

To conduct its work effectively the bureau is directed by a chief directly responsible to the secretary of agriculture. Under his immediate supervision are the general administrative officers, and the heads of six technical divisions, as follows:

1. Division of Biological Investigations.—Under this head are grouped most of the fundamental scientific investigations of the bureau. The scientific staff is made up of experienced mammalogists, ornithologists, herpetologists, and botanists. They make taxonomic studies especially of groups of mammals and birds and identify specimens sent in by field parties as well as great numbers sent by individuals and institutions throughout the country. Some of the results of these studies have appeared as monographic revisions of genera of birds and mammals and the descriptions of hundreds of species and geographic subspecies of mammals, birds, reptiles, amphibians, and plants new to science.

The members of this scientific staff also are leaders of the field expeditions sent out to determine the distribution and habits of wild-life species. During the entire history of the bureau, biological field explorations have been among its major undertakings. Parties of trained field naturalists have done intensive work over a large part of the United States, and in Alaska, Canada, Mexico, Guatemala, and Panama. Many of these expeditions have gained a definite knowledge of the faunas and to a minor extent the native floras, of great areas, which up to that time had been almost unknown. Among the most notable of these have been expeditions to the Hudson's bay region and the Mackenzie river in Canada, to remote parts of Panama, and explorations covering every part of Mexico during a period of 14 years.

Early in the history of the Biological Survey the then chief, Dr. C. Hart Merriam, developed the idea defining transcontinental life zones dependent on the distribution of life as determined basically by temperatures, mainly during the breeding, growing, and fruiting seasons, modified by humidity and other factors. One of the principal objects of the field work of the bureau has been to determine the characteristic species of mammals, birds, reptiles, amphibians, and plants of the different zones. The information so obtained with that available from other sources has supplied the data from which a life zone map of North America has been produced. A systematic series of life-zone surveys of several States is in progress and for some it has been completed and the results published with zone maps. To complete a life zone survey of a State requires intensive field work in every part of its territory to cover all the varying contours and elevations, since the distribution of life is often dependent on special local conditions.

The study of the migration of North American birds throughout the United States is another project that has been carried on from the beginning. Several hundred co-operating volunteer observers have for years kept track of and reported upon the movements of birds during the spring and fall migrations at stations

in many parts of U.S.A. and Canada. The information gathered from these and other sources has supplied valuable data.

With the enforcement of the terms of the Migratory Bird Treaty with Great Britain was developed the need of having more exact knowledge of the migratory travels of individual birds. To obtain this the bureau took over in 1920, from the private organization that had it in hand, the banding (or ringing) of birds and developed this method of research into an international programme through the co-operation of Canada. By the end of 1927 the voluntary co-operators banding birds numbered more than 1,200, and had become organized into four regional associations covering all parts of the United States and Canada; more than 384,000 birds, mainly migratory species, had been banded; and about 16,000 had been retaken, thus supplying invaluable information concerning their travels. The information thus obtained in regard to ducks, geese, and other migratory wild fowl is of very practical value in connection with the administration of the Migratory Bird Treaty Act.

To gain a more definite knowledge of the bird population of the country, a system of censuses or counts of breeding birds is being made on definite areas during successive breeding seasons. More than 100 censuses of this character have been made by volunteer enumerators through a term of years, with such closely corresponding results at widely separated localities as to indicate their approximate accuracy. These counts show averages of about 2.5 breeding birds to each acre of farming land, of one breeding bird to from 1.5 to three acres of open prairie land, and one breeding bird to from one to two acres of forest.

By 1920, the amazing increase of the reindeer herds in Alaska demanded attention as a new form of animal husbandry. To meet the situation an accomplished veterinarian and parasitologist and two grazing experts were placed in the field to try to overcome some of the troubles that had arisen in handling the herds. The results of this work, which is still continuing, have been of the greatest practical value. Many of the troubles with parasites have been much lessened and the methods of herd management have been greatly improved.

Experiments are being made to breed up the reindeer by crossing them with the larger wild caribou bulls from the interior of Alaska. The first crosses as yearlings are much larger than the pure-blooded reindeer in the same herd.

Through co-operation of the Biological Survey with the Department of Interior of Canada, two young Canadians familiar with the northern flora spent the greater part of a year in the field with the experts of this bureau among the reindeer herds in Alaska for the purpose of learning the methods of herd management, with a view to establishing the reindeer industry in northern Canada. This is now being undertaken.

A reindeer experiment station has been established by the survey at Fairbanks in co-operation with the Alaska Agricultural college. Breeding experiments will be continued there with a view to improving the reindeer by developing larger and more hardy stock and also experiments to develop beyond its present abilities the reindeer as a winter draught animal in the north.

2. Division of Food Habits Research.—The major work of this division is the study of the food habits of birds through field observation and by the detailed laboratory examination of the bird stomach contents, usually under the microscope. This requires skilled entomologists, who must also have a thorough knowledge of plants and their seeds. The stomach contents of more than 95,000 birds have thus been investigated. The contents of many other stomachs also have been examined to determine accurately the food of big game, carnivores, rodents, reptiles and amphibians.

The analyses of stomach contents have supplied much of the information on which are based the laws protecting insectivorous birds throughout the country. At the same time current problems are constantly arising as to the destructiveness of vast flocks of blackbirds, hordes of crows, and fruit-eating birds, and methods are being developed for the control or destruction of offenders.

A study of the wild-fowl food resources of large sections of the country is being made by a survey of the vegetation of water and marsh areas. The knowledge thus gained is being used by

owners of water areas who obtain the co-operation of the bureau in studying conditions in their waters and in recommending the planting of additional food plants suitable to such localities. Other investigations of a practical nature in relation to the maintenance and production of upland game birds have been in progress for years. During the past five years, in co-operation with sportsmen having large estates in Georgia and Florida, a detailed and comprehensive study has been made of the "bobwhite" quail

BIOLOGICAL SURVEY, SHOWING THE TRANSCONTINENTAL LIFE ZONES INTO WHICH NORTH AMERICA MAY BE DIVIDED. THESE ZONES ARE DETERMINED BY THE CHARACTERISTIC BREEDING SPECIES OF MAMMALS, BIRDS, REPTILES, AMPHIBIANS AND INVERTEBRATES, ALSO PLANTS, WHICH ARE INDIGENOUS TO THEM. THE DISTRIBUTION IS DEPENDENT, BASICALLY, ON TEMPERATURE. THE IRREGULARITY OF THE ZONES IS CAUSED BY VARIATIONS IN TEMPERATURE DUE TO DIFFERENCES IN ALTITUDE AND HUMIDITY.

with a view to the control of its enemies and the better maintenance of its numbers. One startling result of this work was the determination of the fact that over a large area of typical "bobwhite" country more than 80% of the nests were destroyed each season by enemies.

Investigations on a considerable scale have continued through many years to learn the effective methods of attracting useful birds and increasing their numbers about towns, on farms, and in forests. From the examination of their stomachs, the favourite food plants of many species have been learned and bulletins have been issued giving information concerning the more desirable kinds of plants to introduce or to encourage in different sections of the country.

The breeding of ducks, geese, and other wild fowl in captivity is being thoroughly studied, in order that this utilization of wild life may be developed and thus provide game for the market now that the supply of wild birds has diminished until their sale is no longer permitted.

All the studies named are essential to the building up of American wild life resources, and supply economic information needed in connection with the control of the harmful species.

3. Division of Fur Resources.—The decrease of certain fur bearers and the increasing numbers of furs being brought to market to meet the growing demands of increasing population are danger signals of a possible world shortage of furs. From the beginning of fur farming (*q.v.*) the Biological Survey became active in helping build up the industry along conservative lines as one means of possibly easing the situation for the wild fur bearers. The bureau established an experiment station in northern New York State. There in June, 1927, were held 75 foxes, 6 martens, and 128 rabbits. This station has been the source of much practical service to fur farmers. The use of rabbit skins for fur has developed rapidly within a few years, and the Biological Survey in co-operation with the rabbit growers of southern California in 1927 established a rabbit experiment station in that region.

4. Division of Economic Investigations.—This section of the bureau deals with the problems arising from the depredations of injurious mammals, both the predatory species and rodents, and their control. The predatory-animal problems lie mainly in the grazing States west of the Mississippi, where millions of sheep and cattle occupy the open ranges on the national forests and neighbouring open plains. The habits of the stock-killing animals are studied and extensive experiments made in methods of trapping and in the use of various deadly poisons. Of recent years poisoning methods have been developed that are proving very effective.

The destruction of noxious rodents is carried on mainly by the use of poisoned grain or pieces of vegetables coated with strychnine or other poison. To deal effectively with rodents requires an intimate knowledge of their food habits. Hundreds of millions of acres, including the best farming lands in their territory, are infested with one or more species of injurious rodents, which, uncontrolled, in some districts render agriculture unprofitable. In each of the Rocky Mountain and other Western States, where the injury is greatest, the bureau has headquarters at the capital or other central point. There the leaders of the predatory animal and rodent work have offices and guide the work of their forces and of the co-operating farmers or stockmen in the districts in which operations are being conducted. The field work is planned to cover certain areas under the direction of experienced men, and great numbers of traps, poisoned grain and other supplies are furnished from headquarters. The capture of certain cunning wolves or other notorious stock-killers at times requires a long persistent hunt, sometimes extending over weeks or even months.

The house rat has to be combated mainly in towns and about other habitations of men. While millions of the pests have been poisoned, the most effective and far-reaching work against them has been in bringing about the cleaning up of trash piles and other shelter, the rat-proofing of new and old buildings, and the isolation of food in rat-proof storage and other containers.

In order to continue the production of the best poison combinations for rodents and baits for predatory animals, a well-equipped laboratory is maintained in Denver (Colo.) There during the year 1927, 127,000 ounces of strychnine were used for the purposes mentioned.

The Biological Survey has had two striking problems of national significance to solve in relation to wild animals. First, the control of rabies among coyotes and other wild animals, which had spread from California over four neighbouring States and was threatening to extend with appalling results over all the remaining Western States. In 1916, when the task of stopping this was given the bureau, the disease spread from Nevada into Utah before the organization to control it had been completed. The loss in all kinds of livestock for the preceding year in Nevada was estimated by the stock-owners to exceed \$500,000. During the first year of operations the spread of the malady was stopped by a campaign to destroy predatory animals in great numbers over six States, and within the next two seasons it was completely under control. Since then outbreaks of rabies have occurred repeatedly in widely distributed areas in the Western States, but all have been promptly suppressed by concentrating about them strong

forces of hunters, who have cleaned up the wild and domestic predatory animals serving as carriers.

The second great problem was concerned with the suppression of the foot-and-mouth disease among the deer on the western slope of the Sierra Nevada in Stanislaus County, California. This disease had been imported into the State and before all the infected livestock had been killed the infection had been spread on the range along a part of the mountain slope among the mule deer, which were abundant all along these and neighbouring mountains for hundreds of miles. The general spread of the disease among the deer along the ranges would have infected many thousands of cattle and sheep and would have meant a quarantine against California by all the other States. The result would have been losses running into vast sums and the temporary wrecking of the States' agriculture and commerce. A large corps of the best hunters, numbering more than 200 at one time, was employed and a series of camps established encompassing the lower border of the territory towards which approaching winter would force the deer as snow came higher up. By the use of rifles and other methods more than 23,000 mule deer were killed in this infected area. About 10% showed signs of the disease. In the spring, men were stationed in the mountain passes and no deer were permitted to make their accustomed way across for fear of infecting the far slope. This campaign proved to be an absolute success and not an infected deer was taken outside the "iron ring" of hunters. No trace of the disease has since appeared in this area. It is now being restocked with deer, and grazing there by livestock has been resumed.

In the various phases of this economic work the bureau has had hearty co-operation from several Federal bureaus, State officials, farmers, sportsmen and others interested.

5. Division of Game and Bird Reservations.—Five big-game reservations under game-proof fence in the western United States and 73 bird reservations located in all parts of the United States and its outlying territory, including Alaska, Porto Rico, and the Hawaiian islands, form a series of sanctuaries where wild life is maintained under special guardianship. The National Bison Range, the largest of the fenced big-game areas, has more than 18,000 ac. in western Montana. It contains about 652 bison, 69 mountain sheep, 328 wapiti ("elk") and more than 180 white-tailed and mule deer. It has been demonstrated there, as well as on other reservations, that all these kinds of big game thrive and increase in captivity under proper conditions. In connection with the maintenance of the big game on the reservations and also on the national forests, studies are now being made of the forage plants utilized by game. The occupation of the game country by man and his flocks and herds throughout the West has given rise to difficult problems related to the up-keep of the game supply. These the Biological Survey is helping to solve.

The largest wild life refuge in the United States is on the upper Mississippi, and includes much of the river bottoms for about 300 m. on both sides of the river. The Aleutian reservation includes all of the Aleutian chain of islands, extending in a line from the mainland of Alaska westward between Bering sea and the Pacific ocean for a distance of about 1,000 miles. On some of these islands blue fox farming and sheep grazing are now being conducted without detriment to the reservation.

6. Division of Protection of Migratory Birds.—In 1916 a treaty was negotiated with Great Britain to protect the hosts of wild fowl and insectivorous birds that migrate through the United States and Canada each spring and fall. The protective laws and regulations are administered through a division of the bureau organized for the purpose. Federal game wardens widely distributed throughout the country patrol the main hunting areas in co-operation with the game wardens of the States. Owing to the growing scarcity of game and the enormous increase in the number of hunters, the hunting of migratory wild fowl after Jan. 31 each winter and the sale of this game at any time is forbidden. Since this law and its regulations have been in force many of the States have changed their laws affecting migratory birds to conform with the Federal provisions, and this greatly increases the effectiveness of the protection given the birds.

Federal reservations covering a great area in the aggregate have been established, and efforts are being made to increase their number to offset the effects of the drainage of the great water areas required by the birds. The need of vigorous protection of migratory wild fowl is shown by the fact that for the hunting seasons of 1925 and 1926 approximately 5,500,000 hunters went afield in the United States, a large percentage of whom hunted migratory wild fowl. The collection of migratory birds for scientific or propagating purposes in the United States may be done only under special permits issued through this bureau.

This division also enforces the Lacey Act, which in regulating interstate commerce in game and furs prohibits traffic in them contrary to State laws. Thousands of violations of State and Federal laws are detected each year and valuable assistance is thus given the States in conserving their game and fur resources.

The importation of wild mammals and birds is required by law to be under permit. Agents of the bureau at the principal ports of entry inspect each shipment on arrival. Permits for the harmless kinds are recommended and promptly issued. Harmful species, such as the mongoose and the fruit bat, are denied entry.

(E. W. N.)

BIOLOGY, the science of organisms, an inquiry into the nature, continuance and evolution of life. The term may also be used comprehensively to include botany, zoology, bacteriology (*q.v.*), protistology and the other special sciences that have to do with particular kinds of living creatures. Thus in Herbert Spencer's classification of the general concrete sciences, biology occupies a central place, with its foundations in chemistry and physics, and leading on to psychology and sociology. This is a convenient classification, particularly useful in emphasizing the central position of biology; but there is something to be said in favour of a classification simpler still. It is practically impossible to separate chemistry and physics, and it is inviting fallacy to separate biology and psychology. Thus it may be simpler to recognize three great orders of facts:—(1) *the domain of things*, entirely describable (in their present occurrence) in terms of matter and energy, *i.e.*, in terms of protons, electrons and radiations or ether-waves; (2) *the realm of organisms*, from microbes to mammals, whose activities require for their description certain concepts or categories, which transcend those of mechanism; and (3) *the kingdom of man*, in which the units are not individuals, but societary forms with a continued tradition. For these three orders of facts, the terms *cosmosphere*, *biosphere* and *sociosphere* have been suggested, with the corresponding sciences—*chemo-physics*, *biology* (or *bio-psychology*) and *sociology*. In any case, there is value in the elementary, yet fundamental, idea, that the domain of things encloses and interpenetrates the realm of organisms, and that the kingdom of man is within the larger rubric of organism. Within the immense ellipse of the cosmosphere is the minute ellipse of the known biosphere, and within that again the still more minute sociosphere. When man domesticates animals he is taking part of the biosphere into his kingdom; and similarly he acts on the cosmosphere in gigantic operations such as a Panama Canal. When earthworms make soil, or green plants make oxygen, the biosphere cuts into the cosmosphere; and into the sociosphere when bacilli cause plagues or the forest closes in on the village. So the cosmosphere irradiates both the realm of organisms and the kingdom of man, it may be killing in the lightning flash or invigorating in the sunshine. It is impossible to read either human history or the ascent of life without the assistance of the climatologist.

Biology may be used, then, in a comprehensive way to include all the special sciences that deal with different parts of the biosphere; but the stricter usage, which began with Treviranus and Lamarck, is in reference to the study of the larger or deeper questions that apply to all sorts of living creatures. In this sense the biologist inquires into the nature of the particular kind of activity that we call "life" (*q.v.*). A third usage, common in Germany, is as an equivalent for *bionomics* or *ecology* or *ethology*. This is indefensible and should be discontinued.

Subdivisions of Biology.—In regard to organisms there are eight main biological questions that may be asked, and the answers

to these form the sub-sciences of biology. (1). The question may have to do with form and structure, with organic architecture and internal arrangements; with the static aspects of the living creature. When the instruments are scalpel and forceps, the answer is anatomy. When the microscope is used, and an analytical method such as section-cutting, the answer is histology. The general principles of organic architecture, as contrasted with the anatomical and histological details, constitute morphology; and the history of this inquiry has been a gradually deepening analysis, of the intact organism, with its shape and symmetry, of the component organs with their homologies, and thence of the tissues, the cells and the stereochemistry of the living material itself. For it is a morphological problem to find out what kind of spicule is characteristic of a particular kind of sponge or what crystalline form is taken by the haemoglobin of this or that mammal when the blood is artificially dried. The first question is: What is this, in itself and in all its parts; what is its structure, macroscopically and microscopically? The answer is: *Morphology*.

(2). But the study of structure leads to the grouping together of organisms that resemble one another in their fundamental architecture. Morphology points the way to *Taxonomy* or classification, and that in different grades—species, genus, family, order, class and phylum. This is not merely for the sake of convenience, it is based on the discovery of deep-seated resemblances in structure and development,—homologies. Classification aims at being an expression of actual relationships or affiliations between the different types. In most cases, this end is still remote.

(3). The obverse of morphology is *Physiology* (*q.v.*), the study of activity or function. The morphologist is concerned with static relations, the physiologist with dynamical, but the two aspects are obviously complementary. Symmetry, *e.g.* radial or bilateral symmetry, has to be correlated with the animal's manner of living; the structure of the heart must be studied in the light of its function; and, on the other side, physiology has to analyse a resultant into the components that are contributed by the individual parts. And as the history of morphology has been a persistently deepening analysis, so physiology has passed from the study of the intact organism's activities, to inquire into the working of the organs, the tissues, the cells and even of the particles in the living matter itself.

(4). Conventional physiology restricts itself in the main to the activities of the individual, especially the everyday animal functions of contractility, irritability, nutrition, respiration and excretion, and the corresponding functions in plants. But in the study of the reproductive function it is necessary to pass beyond the individual, and thus there arises what has been called "the higher physiology," the study of habits and inter-relations. This corresponds to a large extent to the old Natural History, now called *Ecology* (*q.v.*). What are the dynamic relations between parents and offspring, between the members of a family, a herd, a community or an association? What linkages bind one kind of organism to another, it may be in the quest for food, or in the avoidance of enemies, or in the continuance of the race, as in the part insects play in pollinating flowers, or the part birds play in distributing seeds? In ordinary respiration there is a give and take between the individual organism and the immediate environment; and this is obviously a question of ordinary physiology. But the swaying balance between the insects and the flowers of a given district, or between the rodents and the vegetation, or between the vegetarian and the carnivorous animals, is a problem of ecology.

So far then four sub-sciences have been recognized,—morphology and taxonomy, physiology and ecology; and these may be arranged (after Patrick Geddes) as tables on the following page¹.

(5). A fifth clear-cut question inquires into the individual development, and the answer is *Embryology* (*q.v.*). In so far as this consists in describing the structure of successive stages in the individual becoming, it is a morphological study, and might well be called *embryography*. But of recent years the inquiry has

¹This scheme applies to multicellular organisms and needs modification for others.

Protoplasm	Protoplasm

MORPHOLOGY

PHYSIOLOGY

become more and more physiological, seeking to analyse the conditions of growth, the play of stimuli, the influence of one part on another, and so forth. This study is often called Developmental Mechanics (*Entwicklungsmechanik*) or Developmental Physiology; and some would separate it off from embryography, just as physiology is separated from anatomy or morphology. The term embryology, which would unite the morphological with the physiological analysis of development, must not be taken too literally; for the word "embryo" refers strictly to the stages before the developing organism gets free from the egg-shell or egg-envelope, whereas the science has also to do with the later stages such as larva and young creature. Indeed it may be suggested that the science of development should logically include the biological study of adolescence and maturity, of the reproductive period and of senescence. It is a study of the organism in its time-relations. It is an analysis of the course or trajectory of the individual life, though for practical purposes it is restricted to the period before the "finished form" is attained. Embryology may be subdivided like anatomy and physiology. Thus organogenesis is concerned with the development of organs, and histogenesis with the development of tissues. Even deeper is the difficult problem of the division of labour which gives rise to different types of cells—nervous, contractile, glandular, skeletal and so forth. The central problem is how the inherited organization of living matter comes to be differentiated yet integrated.

(6). When the biologist asks how the tadpole becomes a frog, he is an embryologist; but to the question whence came the race of amphibians, the answer is *Palaeontology* (*q.v.*) In other words, embryology has to do with individual development (ontogeny), palaeontology, with racial evolution (phylogeny). The main material of the palaeontologist is of course to be found in the fossils in the rocks, but in his task of reconstructing the past and disclosing the advance of life through the geological ages, he may be able to utilize hints afforded by the comparative anatomist's study of the extant, and by the embryologist's dis-

closure of the individual development. Palaeontology should be more than palaeontology,—an anatomy of fossils; it fails of its ambition unless it also does something to reveal the great events in the historical advancement of life. Palaeontology describes as far as possible the gradations from one species to another, the connecting links between distinct types, the presumed affiliation of a class, and even the origin of a particular association of organisms. Thus there may be distinguished a palaeontology of species, of types, of classes, of phyla and of associations. With the last may be included an inquiry into geographical distribution, *i.e.*, as to how different regions have come to possess similar or dissimilar faunas and floras. In essence palaeontology is a description of the stages by which organisms have come to be as they are.

If embryology and palaeontology are linked under the rubric *historical*, since both describe processes of Becoming or Genesis, individual and racial, the following schema may be useful

PALAEOLOGY	Fauna and Flora
	Phylum
	Class
	Type
EMBRYOLOGY	Species
	Fully-formed Organism
	Organogenesis
	Histogenesis
	Cytogenesis
	Differentiation in general

(7 and 8) Huxley applied the useful term *Aetiology* to the study of the factors that have operated in the process of organic evolution. It is one thing to state that birds evolved from an extinct stock of reptiles; it is another thing to be able to indicate, by analogy from the present day, what factors were at work in this notable emergence. Here is included much of the study, in part experimental, of variation and heredity (*qq.v.*), selection and isolation. Aetiology is the study of the causes of phylogeny, it might be pardonable to call it a scientific philosophy of the history of organisms. P. Geddes has suggested that it may be useful to make a separate division for the study of the causes of ontogeny, an inquiry into the factors operative in individual development, not racial evolution. This would include the general part of physiological embryology, the whole question of the plastic influence of the environment on the individual, and much of what is now called genetics, a term suggested by W. Bateson for the science of heredity and variation. The whole diagram may now be put together

	PALAEOLOGY	TAXONOMY	ECOLOGY	AETIOLOGY

Illustrations of Modern Biology. Morphological.—New types continue to be discovered, both extant and extinct, which have to be anatomically described. One thinks of the giraffe-like okapi from west African forests and the tiny antenna-less *Acerentomon*, an elusive precursor of winged insects. The "Challenger" Expedition brought home such prizes as *Cephalodiscus*, a distant relative of *Balanoglossus* (*q.v.*), amongst the pioneer Chordate animals, and this kind of connecting link continues to be discovered. The sea continues to be a well of surprises like the Indian Ocean Alcyonarian *Studeriotis*, whose polyparium of hundreds of individuals can be retracted into a densely spiculate cup, sometimes the size of an orange. Not only are new types still forthcoming, but the old ones are analysed more intimately than before. The modern knowledge of *Amphioxus*, which lends itself so readily to exhaustive sectioning, is far more thorough than the best anatomy of Cuvier's days. Yet many keen eyes had examined it before Boveri discovered its 90 pairs of kidney-tubes. The same might be said of the not less interesting *Peripatus*, which seems to unite the Annelid and the Tracheate lines of evolution. Improvements in microscopic and microtomic technique have made morphological analysis more searching and thorough than it used to be. This is particularly true in regard to the cell, which is disclosed as a microcosm with unexpected complications—centrosomes and chromidia, Golgi's apparatus and mitochondria, and within the cytoplasm the nucleus which is another little world in itself (*see* CYTOLOGY, *Cell Inclusions*).

Taxonomic.—The ambition of many a post-Darwinian taxonomist was to make a genealogical tree, showing the relationships of the phyla, classes and orders—an entirely legitimate ambition when there are sufficient data. But most genealogical trees have crumbled in parts; and it must be admitted that we know very little that is certain in regard to the origins of the chief phyla, such as Vertebrata, Mollusca, Arthropoda or Annelida. More is known in regard to classes, but while all zoologists are agreed, since Huxley's day, that birds are affiliated to some extinct reptilian stock, there is no certainty in regard to the precise pedigree. Yet in regard to more detailed questions, such as the classification of birds and fishes, insects and spiders, Echinoderma and Coelentera, much progress has been made. It seems, at first sight, strange that the taxonomists should be puzzling still over the old question: What is a species? but the inquiry has deepened (*see* SPECIES). Thus there has been a disclosure of specificity—*i.e.*, of the cytological, biochemical, even habitudinal individuality or idiosyncrasy of any species worthy of the name. Probably every "good species" has its own protein. Then there is the discovery, for plants in particular, that a series of species believed to be nearly related on account of macroscopic resemblances, may show a regular progression in the number of their chromosomes, *e.g.*, in a series of four species of rose, the chromosomes are 14, 28, 42 and 56 respectively. Thirdly there is the experimental attack on the species-problem, which is throwing some light on the puzzling inter-specific discontinuity and frequent sterility. It is becoming clear, however, that in many cases at least, the term species is only a convenient label, and that species are usually not sharply marked off in time and often not in space.

Physiological.—The aspect of the science has been profoundly changed by a series of modern discoveries. Thus, as has been pointed out already, to the integration effected by the nervous system and by the common medium of the blood, there has to be added the specific biochemical integration due to the regulatory hormones. Similarly the modern account of the movement of the sap in a tree has become, on the one hand, simpler, because of a clearer understanding of the rôle of the water-columns in the wood-cells and wood-vessels, and, on the other hand, subtler, through a recognition of the probable influence of hormones in the vessels of the bast. Modern biology has been profoundly affected by some understanding of the significance of the colloidal state, of semi-permeable membranes, of substances in the form of films. Some progress has been made towards a better understanding of ferments or enzymes, which play an important part in vital processes. In short, biochemistry is exerting a transforming influence in biology, as is illustrated in the article COLOURS OF ANIMALS.

Since the contraction of muscle fibres enables most animals to move about, and also secures in the majority the circulation of the blood and the passage of the food down the alimentary canal, it is one of the most important processes in the animal body. It is not yet more than partially understood, but it has become much more intelligible within recent years. The researches of Fletcher and Hopkins have shown that the stimulation of the muscle fibre is associated with the liberation of lactic acid which in some way or other induces a physical change in the fibre, namely contraction. Thus we can understand better why there must be a re-instatement of the lactic acid or its chemical precursor into the fibre if it is to continue effective; and there are interesting theories which suggest how the restitution of lactic acid may be effected. Part of it seems to be burnt up to supply the energy to reinstate the remainder. We cannot do more than touch the subject, but it is a good illustration of the way in which chemistry and physics are being applied to the elucidation of an everyday function. One cannot expect an understanding of the whole process to be easy; for, as Sir Charles Sherrington has put it, "The engineer would find it difficult to make a motive machine out of white of egg, some dissolved salts and a thin membrane, which is practically what nature has done in the exquisite artifice of the muscle fibre!"

The physiology of reproduction (*q.v.*) in animals has been much influenced by the modern study of hormones (*q.v.*). From glandular tissue entangled within the reproductive organs or gonads, essentially germ-cell-producing, hormones pass into the blood and are distributed throughout the body, activating adolescent changes in their manifold expression. The male frog's swollen first finger, the courting adornment of many cock-birds, and the antlers of stags are familiar instances of masculine peculiarities, instigated by the reproductive hormones. In many cases the female includes in her inheritance the factors of masculine characters, but these lie latent, because the liberating stimulus is absent, or because they are inhibited by an antagonistic female hormone with an opposite influence. This explains how a duck from which the ovary has been removed may at the next moult put on the brighter livery of the drake, and assume some of his ways as well. Crowing hens and egg-laying cocks are no longer hopeless puzzles. Not less important are the hormones associated with the female reproductive organs in mammals, for they prepare the mother for the development of the offspring in the uterus and for its demands for milk after it is born. Very interesting lights are being shed on the intimacy of the ante-natal partnership between the mother and the unborn offspring. For it has been discovered that there is a passage of regulatory hormones from the mother to the developing offspring, and also a passage of hormones from the offspring to the mother, which contribute to her health. Thus there is a literal symbiosis, correcting the old ugly idea of "the foetal parasite."

The male organism is essentially a sperm-producer, the female an egg-producer; and there are some animals, such as sea-urchins in which the sexes are so closely alike that they cannot be distinguished without a microscopic or a very experienced inspection of the reproductive organs. What lies behind this essential difference between males and females remains obscure (*see* SEX); it finds expression in two microscopically indistinguishable threads of a mould, as well as in the staring contrast between peacock and peahen. There are, as we have mentioned, differences in the sex-hormones, but may there not be some deep constitutional dichotomy leading to this difference? Again, there may be a difference in the chromosomes, as when the female has in every cell of the body one more chromosome than the male (woman having 48 and man 47), but what is there in the presence of an extra chromosome to account for all the contrasts between the sexes? Thus some biologists have sought to discover physiological differences between the sexes, and we take this as an instance of a modern inquiry. It has long been known that males and females may differ in constitutional details, as in the number of red blood-corpuscles and the proportionate amount of haemoglobin. Here, for instance, man is numerically superior to woman. The developing grub of a worker hive-bee has, as regards fat and glyco-

gen, a chemical composition markedly different from that of a grub that is developing into a drone. In many cases the blood of a caterpillar that is developing into a female butterfly is greenish, while that of its neighbour that is developing into a male is light yellow or colourless. This points to a difference in the chemical routine or metabolism of the body.

In 1889 P. Geddes and J. A. Thomson suggested in *The Evolution of Sex* that the fundamental sex-difference behind all the minor contrasts was in the ratio of anabolic to katabolic biochemical processes, A/K in the female being always greater than a/k in the male; and of this theory there has been some experimental and much observational confirmation. A germ-cell whose rate and rhythm of metabolism (measured, for instance, in pigeon's eggs by Oscar Riddle) inclines to a large A/K ratio, will tend to develop into an egg-producing female, with the expression of feminine characters. Conversely, a germ-cell whose a/k ratio tends to be much smaller, will tend to develop into a sperm-producing male, with the expression of masculine characters. And if it should be asked why there should be these alternatives in the A/K ratio, the answer is that this is a universal variational dichotomy, comparable to low gear and high gear. It finds expression in the contrast between ovum and spermatozoon as cell-types; between plants and animals as sub-kingdoms; between Sporozoa and Infusorians as sub-phyta; between reptiles and birds, as classes; between hydroid and medusoid as phases in one life-history, and so with thousands of bifurcations on the path of life. It is often illustrated by variations, of lizards for instance, within a species. It may also be recalled that one and the same organism may in the course of its life change normally from one sex to another, as is illustrated by the hagfish, *Myxine glutinosa*.

In 1923 Manoiloff described a chemical test that enabled him with notable success to tell whether a sample of blood had been taken from a male or from a female animal. To a diluted half-transparent emulsion of blood in salt solution he added, drop by drop, a succession of reagents. After the treatment the emulsion of blood from a male was colourless; that from a female was coloured. Out of 530 tests Manoiloff had about 96% right answers, and two of his students had 97 and 92% of successes. Many others, however, have been much less fortunate, and the discrepancies are puzzling. As the chlorophyll-green of plants and the haemoglobin of animals are regarded by many biochemists as nearly allied pigments, Manoiloff turned his attention to some of the dioecious plants, such as willow, poplar and dog's mercury. In Manoiloff's hands the sex-test worked almost as well for the plants as for the animals, but some other investigators have not had this experience.

Distinctive of this generation has been the study of reflex actions (*see* PSYCHOLOGY, COMPARATIVE). In the familiar knee-jerk, when a sharp tap below the joint of a crossed leg sends the foot up into the air, the mechanical stimulus leads to a thrill along sensory nerve-fibres to the spinal cord; the nervous impulse—still so much of a puzzle—passes to connecting or associative cells and thence to motor nerve-cells, both in the spinal cord. Thence, along motor nerve-fibres, orders come to the muscles, commanding them, as we say, to contract. The brain is not required at all. A pre-arranged linkage of sensory, associative, and motor spinal neurons is sufficient in itself, with, of course, the muscle-cells to give effect to the motor orders. What occurs is called by the physiologists an "unconditioned reflex," and it is one of the commonest occurrences, both in man and beast. When we shut our eyes at the approach of a missile, or when we swallow what touches the back of our mouth, we are illustrating various forms of the unconditioned reflex, some more complicated than others. So is it when a sea-anemone closes its tentacles on a piece of food, when a crab amputates a badly damaged leg, when an earthworm jerks itself into its hole if the ground vibrates under a blackbird's footsteps, when a plaice puts on the colour of sand on which it has come to rest, when a nestling opens its mouth at the touch of food in its mother's bill—these are illustrations of unconditioned reflexes; and the animal world is full of them. It is characteristic of unconditioned reflexes that they are inborn, that they do not require to be learned, that they are shared by

all members of the species, and that they are often quite independent of the brain for their performance. It should be noted, however, that even in the case of a very simple unconditioned reflex like the knee-jerk, a message goes to the brain to report the occurrence. Moreover, the brain is sometimes able to suppress the normal reaction, as in the case of criminals tried by Oriental ordeals, such as the swallowing of dry rice, which is almost impossible if fear inhibits the flow of saliva.

But the modern development of this line of inquiry which we wish to take as an illustration of physiological progress is I. Pavlov's study of "conditioned reflexes." If a dog is shown a piece of flesh its mouth waters. If a whistle is always sounded when the flesh is shown to the dog, an association is gradually formed between the sound and the prospect of a meal. This association or enregistration may become so strong that the dog's mouth will water when the animal hears the whistle, although there is no flesh in sight. The flow of saliva in the dog's mouth illustrates a "conditioned reflex," and the strength of the reaction can be measured by the amount of saliva secreted. It seems likely that in the everyday early life of animals many of these conditioned reflexes are established, and this is to the naturalist the particular interest of Pavlov's experiments. The established associations work rapidly and are probably life-saving as well as time-saving. A wild animal, such as a lion, will react rapidly to a sound or sight in connection with which a reflex has been established, whereas it may not be in the least perturbed by a much more obvious, but unfamiliar, source of danger, such as the arrival of a motor-car against the wind. The conditioned reflex, though usually based on some much older unconditioned reflex, is always built up in the experience of the individual; and, as in mankind, so among the higher animals, there may be some appreciation of the meaning of the connection.

Ecological.—Ecology (*q.v.*) is the study of life as it is lived in nature, where the circle of each individual's interests is intersected by many other circles—such as kindred, members of the same species, competitors, deadly enemies, parasites, symbions, and so forth. Ecology is concerned with inter-relations and linkages, with ways of living, with adjustments to space and time. Thus it includes the study of numbers and dispersal, of migration and other seasonal reactions. Ordinary physiology is concerned with the internal economy of the individual body, but ecology has to do with external relations. The transition from individual physiology to ecology is in the study of reproduction, for that leads from organism to organisms. A few illustrations may be given of the lines of modern ecological investigation.

The leaf-cutter ants cut off segments of leaf from certain trees and carry them to their underground nest, where they are chewed into a green paste, used as the culture-medium for a particular kind of mould not found anywhere else. This mould forms the exclusive food of the leaf-cutters in their subterranean life. When the queen leaves the nest on her nuptial flight, thereafter to start a new community, she takes with her in a little depression beneath her mouth a sample of the mould, which she plants out as soon as her brood of workers have collected leaves and made a soil of green paste. Naturalists have been long admiringly familiar with the parental care exhibited by many insects, but did anyone suspect the extraordinary nutritive exchange common among social wasps between the nurses and the grubs, and also illustrated among ants and termites? Sometimes the mother-wasps, but oftener the step-mothers or workers, feed the grubs in their cells with the chewed flesh of insects, the jaw-apparatus of the larvae being poorly developed. But when the meal is supplied, and sometimes in defect of it, the larva exudes from its mouth a drop of sweet elixir which is greedily licked off. The demand for this luxury may be somewhat coercive, and the elixir is appreciated and may be obtained by the drones, as well as by the queen and the workers (*see* SOCIAL INSECTS). As the sweet juice is secreted only by the young larval wasps, the exchange or "trophallaxis" tends towards the establishment of a *ménage* in which throughout the season there are continual relays of young ones. The luxury seems to have become almost a necessity

Instances of symbiosis have multiplied greatly within recent years, plant within plant, plant within animal, animal within animal. The last is best illustrated by the highly specialized Infusorians whose sole habitat is the intestine of wood-eating termites, where they do something that is indispensable to the food. By raising the temperature it is possible to kill off the Infusorians without harming the termites, whereupon the insects die, being unable to make anything of the wood. But they can be rescued by introducing a fresh supply of Infusorians. Another remarkable symbiosis is illustrated by some luminous cuttlefishes that shine with a light produced by nests of harmless luminous bacteria, like those familiar on drying fish.

The disclosures of the ecologists are warnings against taking simple views of things. Some beetles that bore in growing wood have no symbionts in their food-canal, but on the walls of their tunnels they grow a mould that yields what is called "ambrosia." The fungus collects, concentrates and prepares the sap, and in some cases it has been proved that the beetles do not eat the wood or sap as such, but depend entirely on the ambrosia. The fungus does not seem to form spores or other elements specialized for propagation, so it is probable that the beetles infect a new tree with surplus vegetative ambrosia cells which have passed out undigested from the food-canal. Ecology makes life more complex. Thus the much-studied life of the hive-bee has been complicated by the disclosure of the nectar-dance and pollen-dance on the honeycomb, in which a worker-bee gives her sisters a clue to treasure-trove. Similarly there is the discovery of the graduated quasi-apprenticeship of the worker through a succession of instinctively discharged duties, and there is the punctilious study of homing. To take the last, Wolf has shown that the homing depends partly on visible landmarks that have been learned, partly on the odour of the hive, and partly on a "sense of direction," which has its seat on the antennae, and is remotely comparable to the sense associated with man's semicircular canals. By the antennae the bee is able to record movements until it begins to "lose count." When bees are fed for the nonce at a point 150 yards due north of the hive, a captured one released from its box flies at once southwards. But if the captive is carried in the box 150 yards due east of the hive and then released, it flies again due south. When it has covered 150 yards (judging the distance to ten yards!) it begins to hesitate, apparently made aware that it is quite wrong. It then proceeds to circle around until it finds the hive by sight and scent. Our illustrations have perhaps been within too narrow a range, for ecology has to do with associations and communities, families and pairs, thrust and parry with the environment and with the seasons, trading with time and trafficking with circumstance, migrations and trekkings, outgoings and incomings, and, of course, with plants as much as with animals.

Embryological.—The old-fashioned morphological embryography has largely given place to experimental and physiological studies of development; but the description of the stages in a life-history can never cease to be an integral part of biology. Johann Schmidt's masterly elucidation of the larval development of the common eel has much interest even for the general biologist, and Leiper's discovery of the story of *Bilharzia* is notable in itself as well as in its practical applications. Of recent years there has been no more striking achievement than Isabella Gordon's description of the building up of the sea-urchin's test, from a few sclerites in the early free-swimming larva to the elaborate edifice of the adult. Notable advances have rewarded the applications of physiological methods and ideas to embryology (*q.v.*). There has been a fruitful study of the regulative and "organizing" influence of one part on another during development, of the rôle of hormones in controlling the rate and rhythm of developmental changes, of the significance of certain environmental factors and of chemical substances in the food. The studies of Julian Huxley and others on dedifferentiation and regeneration (*q.v.*) well illustrate the modern movement, and the experiments of Spemann are outstanding. A few particular discoveries may be mentioned to give more concreteness to the picture. (a) In many cases (even in frogs), it is possible to induce the normal development of eggs without there being any fertilization (see FERTILIZATION). (b)

Many experiments show that a part of an egg may be as good as the whole. A larva may be reared from a fertilized fragment of an Echinoid egg, or from one of the first four cells into which the ovum of *Amphioxus* divides. (c) In certain cases, as in Ctenophores and Tunicates, it is possible to prove that there are specific organ-forming substances in an egg, whose removal is followed by some particular defect in the developing organism. (d) A portion of the optic vesicle of a tadpole grafted under the skin of the larva in an entirely irrelevant place, such as the side, will induce in the cells of the epidermis the formation of a lens, which is the normal function of the optic vesicle in its proper place. (e) If the newly fertilized eggs of the American minnow (*Fundulus*) are exposed for a few hours to a temperature a little above freezing point, a percentage will develop into blind larvae. This experiment shows that the blindness of certain cave fishes need not necessarily be ascribed to the darkness. (f) If the developing eggs of the same fish are subjected to various reagents, such as butyric acid, there result numerous strange monstrosities in eyes and ears, nostrils and mouth, even in heart and fins. The chemical intrusion seems to dislocate and partially dissolve the germinal material, especially towards the head end. This may throw some light even on mammalian monstrosities, for butyric acid sometimes appears in higher animals as the result of some disturbance in the carbohydrate metabolism. A consequent poisoning of the mammalian mother's constitution might result, through the placenta, in monstrosities in the early embryo. (g) If the larva of the blind newt *Proteus* be reared in the laboratory under red light, the developing eye, which is normally arrested in the darkness of the caves, increases in size, reaches the surface of the head, and may continue its development even to the extent of becoming functional. The reason for the red light is that in white light the skin of the larva becomes darkly pigmented, and shuts off the stimulus from the developing eye. (h) According to Baltzer's account of the development of the green worm *Bonellia*, notable for its extraordinary sexual dimorphism, those free-swimming larvae that settle down on the floor of the sea develop into large females with a body an inch or two in length and a flexible food-capturing proboscis which may be a foot long. But those that settle down on the proboscis of a full-grown female, and proceed to absorb the skin-secretion, have their development inhibited, and become pigmy males! Those larvae that Baltzer helped to attach themselves to the proboscis of a full-grown female, but left attached for a very short time, subsequently developed into almost perfect females. Those that he left attached for a long time became the ordinary pigmy males with much simplified structure, which live parasitically in the female. But those left for intermediate intervals of time showed various stages of inter-sex.

There is more than verbal progress in the recognition that embryology cannot be limited to the study of the very young animal. It is plain that the larval, as well as the embryonic, stages must be included, and all the difficult phenomena of metamorphosis. But one cannot logically exclude such strange dis-organizations and re-differentiations as are involved, for instance, in the "brown body" of many Polyzoa. The changes of adolescence cannot be separated off from their antecedents, and thus the broader view of embryology will include the study of the whole organism in its time-relations, even those of senescence. The work of Child on *Senescence and Rejuvenescence* is significant of the broadened modern outlook. It is biologically interesting to compare the life-histories of different types, for they sometimes differ from one another in the relative length of the various arcs on the life-curve. Thus some, like *Peripatus* and the elephant, have a prolonged embryonic period; others, like the lamprey, show a lengthened out larval phase; others have a long adolescence, like the elephant again; and so on. Some, like eels, die abruptly after reproduction, while others continue parental for many years, like Golden Eagles. Some, like Mound Birds, practically telescope the whole youthful period; others, e.g., many fishes, continue steadily growing throughout life. These elongations and telescoping of arcs on the life-curve are undoubtedly adaptive in many cases to particular conditions of environment and seasons. They suggest the

occurrence of what may be called "temporal variations"; and these in higher animals may be correlated with endocrinal peculiarities.

Palaeontological.—The modern advance in palaeontology may be dated from the work of Waldemar Kowalevsky (1874) who devoted himself to a reconstruction of the life of fossil ungulates. He sought to relate his fossils not only to their extinct ancestors and extant descendants, but to their own habits and to their particular environments, both climatic and animate. The distinctive note in the outstanding palaeontological studies of recent years is the reconstruction of the life of the past. The palaeobotanist joins with his zoological colleague, and both take counsel with the geologist and with the climatologist. A further aspect of modern palaeontology is the way in which it has filled in gaps and given us continuous series of fossils.

Aetiological.—The origin of the new remains one of the central problems of biology, but some steps of essential importance have been made since Darwin's day. (1). There is evidence of the frequency of discontinuous variations or mutations, and these illustrate Mendelian inheritance. (2). There is no doubt that many—some would say *all*—visible and somatic variations are due to germinal permutations, combinations and changes. (3). In some cases it is certain that the germinal "factors" or "genes," corresponding to particular mutations, and to all or many of the discrete non-blending "unit characters" of the organism, lie in longitudinal order in the chromosomes of the nuclei of the germ-cell. In the fruit-fly *Drosophila* there are known to be about 7,500 of these "factors"; and their topography has been provisionally mapped out. In the history of the germ-cells there are ample opportunities for their shuffling, which might, and no doubt does result in new patterns. (4). Some experiments show that deeply saturating environmental, nutritional and functional peculiarities—including X-ray radiations—may incite germinal changes. (5). Just as a periodic scrapping and re-organization (endomixis) occurs normally in some species of slipper animalcule, so there may be re-arrangements and re-organizations in the complex nucleus of a germ-cell, which, after all, must be intensely alive. (6). There is strong palaeontological and a little experimental evidence that variations are sometimes definite or orthogenic, *i.e.*, occurring consistently in a particular direction. In other words, a variation may be congruent with what has been already enregistered in the organization of the creature. As a particular illustration we may refer to Erwin Baur's study of mutations in snapdragons, *Antirrhinum majus* and its relatives. The garden races are continually exhibiting mutations, small in amount, but crisp and brusque in character, and transmissible in their entirety in Mendelian fashion. There seems no doubt that they are expressions of slight germinal changes in the hereditary factors.

Various evolutionists who admit the reality of mutations have been inclined to depreciate their importance on the ground that they tend towards monstrosities and represent a weakening of germinal vigour. This may be true in some cases, *e.g.* in fancy goldfishes or waltzing mice, but it is certainly not true of Baur's small mutations in snapdragons, for these are generally well within the limits of healthy normality. They find expression not only in the flower and its colour, but in many parts and characters of the plants. Sometimes the new departures suggest an enhancement of vigour, as in a deeper green in the leaves. In any case, there is rarely any hint of the pathological. In most cases the mutants seem to have taken a small step further along the direction which marks the parental race. After 20 years of investigation of the garden races and wild species of snapdragon, Baur has come to the conclusion that in many cases their distinguishing characteristics are due to the summation of small mutations such as are of everyday occurrence in the garden. In natural conditions the summation may be put to the credit of natural selection, which sifted the new tentatives in reference to the diverse and changeful conditions of locality and climate. This is a characteristically Darwinian conclusion, for Darwin thought much more of the creeping than of the leaping of the eternal Proteus of life. But whereas Darwin was vague in regard to his raw material of "small variations," Baur is very precise in regard to his "small muta-

tions," except as regards their cause. While Baur confirms Darwin's belief in the cumulative importance of small changes, which might be called evolution-jerks or quanta, he is far from saying that these furnish the whole of the raw material of progress. On the contrary, while he lays chief emphasis on minute changes in the hereditary factors or genes,—*changes which occur abundantly even in "pure lines"* (all descended from one parent),—he admits that new departures may arise from the crossing of different strains with different sets of factors. But the existence of these different strains depends in snapdragons on the previous summing up of small mutations. The large transilient variations or freaks, which attract the gardener's eye, can be continued by careful cultivation, but they tend to be eliminated by natural selection as too extreme. The small mutations count for most. It may be noted that, in contrast to roses and some other organisms, the number of chromosomes does not change, being eight in all the species studied.

As regards heredity, the modern position has been profoundly altered (1) by the re-discovery (1900) of Mendelian inheritance, (2) by Weismann's concept of germinal continuity, and (3) by the use of statistical methods. While there are some puzzling phenomena, there is at present no conclusiveness in the evidence adduced in support of the transmission of individually acquired somatic modifications, even to a slight degree. But there is a clearer recognition of the fact that the expression of a character in the course of development is always the resultant of two components—the hereditary "nature" and the environmental, nutritional, and functional "nurture." There have been several violent reactions from the characteristically Darwinian theory of natural selection, but they do not appear to be well-informed. Darwin anticipated the criticism that natural selection does not account for the material to be sifted; he was careful to distinguish other forms of selection besides the immediate lethal elimination of the relatively less fit; he laid stress on the survival value of such non-competitive endeavours as parental care and mutual aid; he laid emphasis on the correlation of variations, as explaining how an incipient new departure, too minute to be of appreciable value, might be carried in the wake of a large and important variation with which it is correlated. Since Darwin's day it has become clearer that natural selection operates in relation to a system of inter-relations—the web of life—already established, a fact which explains how the difference between Shibboleth and Sibboleth may have survival value. It has also become clearer that organisms sometimes take part in their own evolution by playing the hand of hereditary cards with which they have been endowed. It is true that the environment often selects organisms, but it is also true that the organism sometimes selects its environment. Since Darwin's day there have been a few actual proofs of natural selection at work, as in the case of Weldon's crabs and Cesnola's mantises.

Increased attention has been paid to the effect of isolation in its varied forms—geographical, habitudinal, temporal and temperamental—for isolation tends to inbreeding or endogamy, which stabilizes a stock or species, whereas outbreeding or exogamy promotes variability, sometimes almost like an epidemic. There can be little doubt that alternations of inbreeding and outbreeding have meant much in evolution. Careful experiments have shown that inbreeding may be long continued in a vigorous stock without any deterioration, the prejudice against it being due to the mistake of supposing that the not infrequent disclosure of recessive defects in the course of inbreeding is due to the consanguinity as such.

Reconsideration of Sub-divisions.—After this illustration of the scope of biology it may be useful to return to the sub-divisions of the science:—Palaeontology: Taxonomy. Ecology: Aetiological phylogeny. Embryology: Morphology. Physiology: Aetiological Ontogeny. Is there no alternative grouping, for it has been objected (1) that aetiology is not a separate sub-science, but rather the raising of a question that is relevant all through; (2) that the causal investigation of development (ontogeny) is very different from the study of racial evolution (phylogeny), and should not be separated from embryology, (3) that the relation of

embryology to palaeontology is not comparable to that between physiology and ecology, or morphology and classification.

As an alternative grouping it may be suggested that the biologist has to do with Organisms, Functionings and Environments, using each term in the plural, and "functionings" rather than "functions" on the ground that the everyday functions that secure the continuance of the living creature cannot be separated from the organism without leaving a false abstraction.

Organisms may be studied statically (anatomy, etc.) or dynamically (physiology, etc.), and in their time-relations (from embryonic development to senescence). Functionings include all the ongoings and operations of the organisms (ecology). The study of environments includes the whole staging of life, animate as well as inanimate, and that is also to be studied in its time-relations, both seasonal and secular. At every point the evolutionary question may be raised, in regard to each of the three sides: By what steps and by what factors did these organisms, functionings and environments come to be as they are? This removes the awkwardness of having aetiology as a separate sub-section, and of separating the anatomy and physiology of the embryo or larva from the anatomy and physiology of the adult. If the sides of the triangle, a cross-section of "the biological prism," be pictured as convex, the inner surface may represent the psychical, mental or subjective aspect (clearly present in many organisms and functionings and in at least the higher reaches of the animal part of the environment), while the outer surface may represent the protoplasmic, bodily or objective aspect. The correspondence of the biological co-ordinates, Organisms, Functionings and Environments, with the sociological analogues, Folk, Work and Place, is obvious.

APPLICATIONS OF BIOLOGY

It is useful, theoretically at least, to distinguish applied biology from applied zoology and applied botany. When means are taken to check the spread of injurious insects, or the dissemination of malaria by mosquitoes and of sleeping sickness by tse-tse flies, or the damage done by parasites such as the hook-worm in man or the Isle-of-Wight mite (*Acarapis*) in hive-bees, there is an application of zoology to a practical problem. The success of the check often depends on a knowledge of the life-history and inter-relations of the animals involved. Similarly, there is an application of botany in the effort to check the diffusion of plant-diseases and plant-enemies. As regards man himself, as well as his domesticated animals and cultivated plants, great results have rewarded applied botany and applied zoology. But applied biology is somewhat different; it implies the application of general biological ideas, not the specialist's knowledge of this or that animal. Thus Mendelism (*q.v.*) applied to plants and animals is applied biology, and so is the general policy of hygiene and eugenics. An appreciation of the general biological idea of the web of life might have saved man from some of his short-sighted introductions and eliminations, and may assist him in his policy of more economically exploiting the life of land and sea. In coping with the bilharzia parasite in detail there is co-operation between medicine and zoology, but the idea of acting on a knowledge of the linkage between the man and his worm, on the one hand, and between water-lilies and aquatic birds on the other, comes as a suggestion from biology.

Unsolved Problems.—It is not to be supposed for a moment that the science of biology is so far advanced that a list can be

made of its unsolved problems! Yet there are many vital phenomena which are well on the way towards being described in terms of relatively simple or generalized concepts, such as the metabolism or the irritability of protoplasm, while others remain defiantly beyond our present analysis. Some qualitative advance, such as the discovery of hormones, must be made before they become relatively clear; no mere quantitative addition of data will supply the required illumination. Thus biology is still far from understanding the factors operative in cell-division, or what is the most essential event when an egg is fertilized, or how enzymes continue unwearyingly to exert their extraordinary transforming power. There are some very puzzling phenomena, *e.g.*, the case in which a living organ, such as the growing root of a plant, influences a similar organ of another kind of individual, without there being any contact between them.

While the biologist has come to understand how certain kinds of variations or new departures may arise, *e.g.*, by a shuffling of the hereditary cards contained in the chromosomes, or by the interpenetration of some potent environmental influence, it is not possible at present to give any clear account of the origin of a large mutation of a distinctly novel character, though H. G. Muller and others have succeeded in producing large mutations by X-ray irradiation. Yet the origin of the new is the central and inevitable problem of biology. Similarly, while the secure data of Mendelian inheritance have grown in volume with remarkable rapidity, it does not appear to be possible at present to give any reason why one of two contrasted characters should be dominant and the other recessive. On another line, it may be said that some biologists who regard the evidence in favour of Lamarckism as altogether unconvincing, are willing to admit the reality of certain puzzling phenomena which demand further inquiry and some fresh discovery. But the whole subject of organic evolution bristles with unsolved problems!

Returning to the concrete, we may illustrate the kind of unsolved problem to which we specially refer by mentioning the way-finding capacities exhibited by migratory birds. Prolonged experiments with ants and bees seem to have proved that in the majority of cases at this level there is an individual learning of the topography around the hill or hive. But this does not apply to cases like the sooty and noddy terns of the Tortugas which are able in some cases to return to their nests after being transported in closed baskets for a thousand miles and liberated in seas previously unknown.

Major Problems of Biology.—The biologist begins with simple forms of life, like some of the simplest Protista of to-day, and supposes that from these, by a continuous sequence of natural processes, all other organisms have been evolved, in the course of some hundreds of millions of years. But the first question is, how the postulated simplest organisms began to be upon the earth. To suppose, with Kelvin and others, that germs of life reached the earth from elsewhere, in the crevices of a meteorite or in cosmic dust, is not an easy hypothesis; and in any case it only shifts the problem. It must be kept in mind that the existence of protoplasmic organisms is not possible except in a relatively cool corner of the cosmos, where water is available in a liquid phase. The only other scientific suggestion is that simple living creatures may have arisen from non-living materials by processes of natural synthesis. This synthesis may have been due to the prolonged action of light on water containing carbon-dioxide and nitrite of ammonia, or the like, brought down by rain after a thunderstorm. It is interesting to recall the achievements of the synthetic chemist in building up such complex substances as amino-acids, but the difficulty is to suggest the natural conditions that would play the chemist's part. In this connection the experiments of Baly and his collaborators are of much interest. For he was able to produce first formaldehyde and then sugar by prolonged illumination of water containing carbon dioxide. Furthermore it was found possible to induce the formaldehyde to unite with nitrites, thus forming nitrogenous carbon-compounds, by the use of ordinary sunlight in the presence of a "metallic photocatalyst," *i.e.*, a metallic substance which makes the energy of light more available. This is probably the function of chlorophyll.

Life is a particular kind of activity exhibited by living creatures. It includes many chemical and physical processes which become more clearly known every year. But these processes of oxidation and fermentation, of surface tension and osmosis, of heat-production and electric discharge, and so forth, are correlated, regulated, controlled and integrated; and it is this unification, leading to effective behaviour, which seems at present to be indescribable in terms of chemical and physical concepts. These have been for the most part developed in reference to changes of matter and energy in circumstances not including life, and it is not to be expected that they should apply to the totality of reactions exhibited in another order of facts, namely those of organisms. It is not behaviour alone that stands by itself, but the capacity for growth, multiplication, development and enregistration. As W. K. Clifford said: "It is the peculiarity of living things not merely that they change under the influence of surrounding circumstances, but that any change in them is not lost, but retained, and, as it were, built into the organism to serve as a foundation for future actions." Since the living organism appears to be a new synthesis, as compared with a stone or a star or a drop of colloidal matter, since it exhibits qualities that cannot be adequately described in terms of matter and energy, it seems good sense to claim some autonomy for biology. The organism is a new synthesis in which certain aspects of reality, previously unexpressed, find expression, and these cannot be adequately described without the use of special biological concepts, such as irritability and enregistration, growth and development, and effective behaviour.

Among birds and mammals there is abundant evidence of the intelligent control of behaviour in reference to a perceived purpose. There is often more than a hint of judgment; endeavour is undeniable; feeling is often strong. The biologist must recognize that he is dealing with psycho-biosis. A Robot theory of the higher animal does not work, and recent well-criticized observations and experiments on the highest apes show that the level of intelligence is higher than the most generous had supposed. On the other hand, there is not less abundant evidence that no small part of animal activity depends on automatic reactions, tropisms, enregistrations and reflexes, both unconditioned and conditioned. It may be said, indeed, that animal behaviour has evolved along two main lines. On the one hand, there is the evolution of the power of fresh adjustment, of making little experiments or tentatives. This is the line of individual initiative and it has its climax in sheer intelligence. On the other hand, there is the evolution of the capacity for the neural enregistration of profitable modes of behaviour, so that they become parts of the inheritance, requiring no more than a liberating stimulus for their activation. In both cases there is inherited capacity, but among "big-brained types," as Sir Ray Lankester has called them, the inheritance is mainly a nimble, plastic, educable intelligence, while among "little-brained types" the inheritance is mainly a stereotyped series of reactions. Now it is one of the major problems of biology to do justice to these two lines, a problem which is the more difficult since they sometimes intersect.

But the attempt to do this is likely to bring the biologist face to face with the still more difficult problem of the relation between body and mind. On the one hand, there is the bodily, the nervous, the physiological, the objective. On the other hand, correlated yet incommensurable, there is the mental, the psychical, the psychological, the subjective. How are these two aspects of reality to be thought of in relation to one another? When are we warranted in stressing the one, and when the other? It remains a difficult problem for the biologist to trace the expressions of mentality backwards to their slender beginnings, both in the individual higher form and in the animal kingdom as a whole; and to probe further back still to what may have corresponded to mind in the non-living materials out of which organisms may have evolved. It seems necessary to assume that a certain degree of organismal intricacy is necessary, both in ontogeny and in phylogeny, before emergence is possible for that aspect of reality which we call "mind," an aspect which is of such predominant importance in the development of The Sociosphere.

Inter-relations with Other Sciences.—In Spencer's scheme biology is the central science based on chemistry and physics, leading on to psychology and sociology. Saying the same thing somewhat differently, we have ranked the study of the realm of organisms (the biosphere) as intermediate between the study of the domain of things (the cosmosphere) and the study of the kingdom of man (the sociosphere).

In the living body there are diverse processes of oxidation and reduction, hydration and dehydration, solution and fermentation and so forth, which can be taken separately and studied by the bio-chemist. Similarly there are phenomena of surface tension, capillarity, osmosis, leverage, hydrodynamics, thermodynamics, electricity and so forth, which can be taken *seriatim* and studied by the bio-physicist. Biophysical and biochemical methods have helped greatly towards a better understanding of the life of the body. They illustrate what Comte called a legitimate and necessary materialism. Biology cannot dispense with the assistance of the more exact sciences. But, even if we had a complete ledger of all the biochemical and biophysical processes that occur when a swallow returns from the Gold Coast to the place of its birth in a Scotch farm-stead, we should not understand the bird's remarkable homing. For that requires distinctively biological concepts. The concepts of chemistry and physics are indispensable in biology, but biology transcends them and requires concepts of its own. The organism transcends mechanism and is a "historic being."

The inter-relation of "body" and "mind" is such as to justify the saying: *nemo psychologus nisi physiologus*; but we sometimes forget to transpose this. An emotional storm stimulates the production and distribution of adrenalin; dyspepsia warps the judgment and dulls good feeling. A blot in the brain may mean a darkening of the eyes of the mind, and the clinical biographies tell us how an eye-trouble may ruin a man's temper. Yet a merry heart is the life of the flesh and good news promotes digestion. Mental and bodily, psychical and neural, subjective and objective are so closely intertwined that it seems to many biologists that their science is really psycho-biology. Similarly, but more distantly, in regard to sociology, the biological foundations cannot be ignored without loss. The units in sociology are societal groups of some sort, but these consist of individuals with all the appetencies and limitations of organisms. There is a social aspect of heredity, of sex, of multiplication and of nutrition. Just as there can be no sound biology that does not keep continually in view the three sides of the prism, Organism, Functioning and Environment, so there can be no sound sociology that does not keep continually in view the social analogues of these: Leplay's "*Famille, Travail, Lieu*." Here the biologist and the sociologist join hands.

(See ZOOLOGY, BOTANY, PHYSIOLOGY, PALAEOLOGY, PALAEOBOTANY, EVOLUTION, SPECIES, etc.)

HISTORY

Biology, in the widest acceptance of the word, is used to cover all those studies which deal with the structure, nature and behaviour of living beings. It is thus in contrast to the word physics which is similarly used to cover the study of the structure, nature and properties of such matter as is neither living nor a necessary product of the activity of living things. It happens that certain of the studies classed as "biological" are intimately bound up with the study of medicine. Such are, for example, human

anatomy, the physiology of the warm-blooded animals, bacteriology and the like. The linking of these departments with medical study has had certain historical and practical results and they are sometimes tacitly excluded from what is called biology in certain narrowed academic uses of that term. As a matter of practical convenience these departments have been considered in the article MEDICINE, HISTORY OF. Here we shall only consider them incidentally.

The word biology was introduced by S. T. Treviranus (1776–1837) in his *Biologie oder die Philosophie der lebenden Natur* (Göttingen, 1802–22). It was adopted and popularized by J. B. de Lamarck (1744–1829, *q.v.*) in his *Hydrogéologie* (Paris, 1802). It is probable that the first English use of the word in its modern sense was by Sir William Lawrence (1783–1867) in his work *On the Physiology, Zoology and Natural History of Man* (London, 1819). There are, indeed, earlier uses of the word in English but they are in relation to biography.

Biology, like other sciences, can be traced to the Greeks. At a very early date, and particularly at the hands of Alcmaeon of Croton (*c.* 500 B.C. *q.v.*), we hear of independent investigations of the structure and habits of animals. Thus Alcmaeon described the optic nerves and tubes that lead from the nose to the ear (Eustachian tubes), and he made a beginning of the study of the development of the embryo. Moreover, the Hippocratic collection (*see* MEDICINE, HISTORY OF and HIPPOCRATES) provides evidence, imbedded in a work on diet, of the existence of attempts to make a classification of animals as early as the 5th century B.C. All the early records of biological science before the 4th century B.C. are, however, either completely lost or too fragmentary to permit of adequate reconstruction. Not until we get to Aristotle (384–322 B.C.) do we encounter any complete biological works. Moreover, as our knowledge of Greek biological science begins with Aristotle, so it may almost be said to end with him. The only surviving ancient works on living things, besides those of Aristotle, that were prepared without consideration of the application of the knowledge they set forth, are by his pupil, Theophrastus. A full account of the biological achievements of Aristotle and of Theophrastus would thus contain an almost complete account of our knowledge of pure biological science as it existed in antiquity.

Aristotle as a Biologist.—Of the biological works of Aristotle a considerable number have survived. Among them, four stand out pre-eminent. They are: (a) *On Psyche*, *i.e.*, on the soul or living principle, usually known as *De Anima*. (b) Histories about animals, usually known as the *Historia animalium*. (c) On the generation of animals, usually known as *De generatione animalium*. (d) On the parts of animals, usually known as *De partibus animalium*.

There are matters in these works which come rather in the department of philosophy than in that of biology (*see* ARISTOTLE) but which must nevertheless of necessity be considered in any account of the history of biological thought which they have influenced throughout its course. Among these matters is Aristotle's conception of the nature of the living principle or psyche.

The oldest use of the word "psyche" is in the sense of breath, and breathing is the most obvious sign of life. It was, therefore, natural that from breath the word psyche came to mean life, then the soul and again the mind. Aristotle used this term for the principle that differentiates living from not-living substance. When he began to examine different living things he reached the conclusion that there were different kinds or orders of psyche or soul. In the course of this investigation he came to distinguish between (a) the vegetative soul, (b) the animal soul, (c) the rational soul.

The first or lowest of these was the vegetative soul. Aristotle regarded plants as the lowest living forms and the qualities of life that he distinguished in plants he regarded as the only qualities essential for this lowest form of soul. These qualities seemed to him to be nutrition, growth and the power of reproduction.

Aristotle considered that while animals had these qualities of the vegetative soul, they also had, of their nature, the power of movement, and the movements that they made seemed to him to

correspond to what they felt. The animal soul thus possessed, as he thought, not only the qualities of the vegetative soul but also a second order of qualities which were responsible for the sensitive and motive powers of animals.

Lastly, man had all these qualities exhibited in the lowest creation, both plants and animals, but he had also certain others. He could reason and his movements and actions were dictated by his thoughts. His soul was, therefore, equipped, in Aristotle's view, not only with the qualities of the vegetative and animal souls, but also with rational or intellectual powers.

It will thus be seen that Aristotle was, in the fullest and most definite sense, a "vitalist." Apart from the classification of kinds of soul Aristotle held certain definite views as to the relationship of this soul or psyche to the living body. This relationship was determined by the existence of an *Entelechy*, a term which may perhaps be translated for biological purposes as "an indwelling purposiveness."

The nature of this Entelechy is perhaps best brought out by quotation from his work *De Anima*, from which it will be gathered that he held that the soul is neither independent of, nor is it identical with, the body.

"They are right," says Aristotle, "who hold the soul as not independent of the body and yet as not in itself anything of the nature of the body. It is not body, but something belonging to body. It, therefore, resides in body, and moreover, a particular soul to a particular body. They were wrong who sought to fit the soul into the body without regard to the nature and qualities of that body. For the Entelechy of each thing comes naturally to be developed in the potentiality of each thing, and it is manifest that soul is a certain Entelechy and notional form of that which has the capacity to be endowed with soul."

This, then, is the basic thought in Aristotle's biological work, and in this sense Aristotle is a modern biologist, for it is the basic thought in much biological work at the present day. But besides Aristotle's finely wrought out biological theories, of which this is one, there is much in his biological writing that does not involve these high topics, but is restricted to the ordinary investigations of the working biologist as we know him in our own time. Foremost among these investigations on the phenomenological level we may note Aristotle's magnificent observations on the habits of fishes, some of which, doubted for centuries, have been verified in our own time. No less remarkable are his observations on the breeding and development of the octopuses and their allies. His discourses on whales, porpoises and dolphins, on the development of dog-fish, and on the habits of bees are also very noteworthy. There is much in his writings to justify us in classing Aristotle as one of the best observing naturalists of all time.

The whole course of biology may be represented as the history of ideas on the classification of living things. Something must be said on this subject in relationship to Aristotle.

At first, Aristotle entirely separated man from the lower creatures, distinguishing him among living things by the possession of a rational soul. As Aristotle's knowledge increased, he seems to have become less inclined to make this absolute distinction and he came to admit that animals in their degree share rationality with man. His final position seems to have been that the distinction between the animal and the rational soul cannot be consistently maintained and that there is no fundamental distinction between life or soul and mind. This is precisely the attitude of an important school of modern biologists.

In ascribing reason to animals Aristotle seems to have been influenced by his advance towards something that we should nowadays call a belief in "Evolution." It cannot justly be said that he ever attained to a clear view of organic evolution. Nevertheless, it is evident that he was moving in that direction, that he was not far from reaching it and that had he lived a few years more it might well have been that he would have reached it. But whether we call him an evolutionist or whether we withhold that title from him, it is certainly easy to read an evolutionary meaning into much of his biological writings. Moreover, we see him groping at some natural manner of arranging the orders of animals. He is, in fact, striving towards what we should call a

"classification." The mechanism that he actually adopted was to arrange living things in a sort of scale. This *Scala Naturae* of Aristotle is a subject of great interest and is worthy of all possible respect. He describes a particular part of this as follows:

"Nature proceeds little by little from things lifeless to animal life in such a way that it is impossible to determine the exact line of demarcation, nor on which side thereof an intermediate form should lie. Thus next after lifeless things in the upward scale comes the plant. . . . Of plants one differs from another as to its amount of apparent vitality. In fact, the whole of plant kind, while devoid of life as compared with animals, is endowed with life as compared with other forms of matter. Therefore, there is in plants a continuous scale of ascent towards the animal, and of some, one is at a loss to say whether they be animal or plant. . . . Thus nature passes from lifeless objects to animals in unbroken sequence, so that scarcely any difference seems to exist between two neighbouring groups by reason of their close proximity."

As a working naturalist Aristotle excelled chiefly in his observations on the habits and lives of animals. He was less fortunate in his investigations of their structure, and less fortunate still in his consideration of the functions of parts. He was, in fact, far less an experimenter than an observer. This is not surprising since he had no exact body of knowledge of experimental physics and chemistry on which to build. Some of his successors among the Greeks, e.g., Galen, far excelled him in their experimental skill and ingenuity.

Ancient Biology After Aristotle.—Aristotle's botanical researches are, unfortunately, lost. We have, however, very full botanical works of Theophrastus of Eresus (380–287 B.C.), his heir, his favourite pupil and his successor as head of the Lyceum. Theophrastus, like other ancient men of science, seems to have felt acutely the need for a technical terminology. He made some attempts to establish one, and at least one technical botanical term, *pericarp*, comes to us from him.

Theophrastus understood the value of developmental study, a conception derived from his master. "A plant," he says, "has the power of germination in all its parts for it has life in them all, wherefore we should regard them, not for what they are, but for what they are becoming." He lays much stress on the different modes of reproduction of plants. He distinguishes between the monocotyledons and the dicotyledons, and he has some interesting passages in which sex is discerned in plants, notably in the palms.

The works of Theophrastus are extremely valuable as perhaps the most complete biological treatises that have come down to us from antiquity. They contain many excellent observations, but are on the whole distinctly inferior in depth, range and insight to the biological works of Aristotle.

Pure biological investigation virtually came to an end with the death of Theophrastus. Biology was studied at the Alexandrian school, but chiefly in connection with medicine and has been considered elsewhere (*see MEDICINE, HISTORY OF*). There was one important development, however, in Alexandrian times to which we may refer. This was the practice of portraying the forms of plants exactly and artistically. It seems probable that science owes this most important accessory art to one Crateuas, a herbalist who practised in the 1st century B.C. There are reasons for believing that we have accurate copies of some of the drawings of this artist, and these copies are therefore of the utmost interest to biologists.

The Hellenistic investigator, whose writings have had most influence on the course of botany, and in particular on botanical terminology, is the physician Dioscorides of Anazarba in Asia Minor. Dioscorides served in the army of the emperor Nero, and a work by him on plants useful in medicine has come down to us in great completeness and in a very large number of manuscripts. Nevertheless, this work is ill arranged, almost devoid of general ideas and steeped in the errors that must always pursue those who follow purely practical ends without regard to theoretical considerations. The work of Dioscorides is essentially a drug collector's manual, and represents a very great deterioration from the Aristotelian standard.

Even lower in quality than the *De materia medica* of Dioscorides is the *Natural History* of his contemporary, Pliny the elder (died A.D. 79). It is immensely interesting as a storehouse of folk-lore and as a mirror of the follies and superstitions of his age. It cannot be passed over in silence since it was perhaps more read during the middle ages than any work of antiquity except the Bible. From the point of view of a rational development of biological thought, however, Pliny's work is beneath contempt.

The only other important later figure in the biological thought of antiquity is Galen. The magnificent apparatus and achievements of this man have been considered elsewhere (*see GALEN and MEDICINE, HISTORY OF*). Though his interests were mainly medical, the vigour and independence with which he pursued his researches give him a very important place in the history of biology.

After Galen, the history of biological thought is a dismal record of steady deterioration for many centuries. Even with the great scholastic and artistic revival of the 13th century, there is little evidence of any systematic firsthand observation. Still less is there any trace of independent biological thought. We do no grave injustice to any writer in passing direct to the revival of learning.

Biology at the Revival of Learning.—Although the scholastic period was barren in biological achievement, there were yet certain elements in its more characteristic developments which became ultimately factors in the revival of biological science. Among these we must give a leading place to the passage towards naturalism in art. This movement first made itself felt in the 13th century, though it did not develop fully until the 15th. Moreover, from the end of the 13th century a certain amount of natural curiosity was satisfied by the process of dissection which, however, was not practised with any frequency until the very end of the mediaeval period. These movements, naturalistic and anatomic, were fertilized, so far as biology was concerned, by the artistic discovery of antiquity. Thus the renaissance of art became also a renaissance of science.

The great artists of the Renaissance period, Botticelli, Leonardo da Vinci, Durer, Michelangelo and others, exhibited an interest in the exact portrayal of animal and plant forms as well as curiosity as to the structure of the human body. As well as being artists these great Renaissance figures were all of them curious as to the ways of nature, and it is not misusing words to speak of these artists as men of science, botanists, anatomists, physiologists and the like. The group of movements which came to flower with the beginning of the 16th century placed the student of nature in a peculiarly favourable position. He had the works of science of antiquity on which to start. The craft of printing was at his disposal. He had the scientific studies of the great artists before him. He had learnt to represent details of nature effectively. At last, also, the art of the wood-cutter was perfected, so that the figures of the artist could be transferred to the printed page.

It was in this happy collocation of circumstances that the first effective biological textbooks of modern times were produced. The movement began in Germany and it began with the botanists. It is the distinction of Otto Brunfels (1464–1534) that he produced the first printed work on plants which relied solely on observation. The drawings are firm and faithful and it is very interesting to compare them with those of a good modern textbook. As Brunfels was the first, so Leonard Fuchs (1501–66) was the greatest, of the German "fathers of botany." His work appeared in 1542 and is the landmark in the history of natural knowledge.

A part of the same movement illustrated by the "fathers of botany" is the new scientific interest in anatomy. Protagonists of that movement (*see MEDICINE, HISTORY OF*) are Andreas Vesalius (q.v.) and Bartolomeo Eustachio (q.v.). More in the class of pure "naturalists" in the modern acceptance of that word were the two French observers, Belon and Rondelet.

Pierre Belon (1517–64) of Le Mans spent some years wandering in the Near East. He kept careful notes of the natural history of the countries that he traversed, basing his observations on his reading of Aristotle. Later he produced two books on fishes and another on birds, which, though borrowing much from Aristotle,

show also much original observation. It is interesting to note the clearness with which Belon grasps the general principles of comparative anatomy, especially as applied to the skeleton. These principles had already been elucidated by Vesalius. More accurate as an observer, though less imbued with comparative principles was Guillaume Rondelet (1507-66) of Montpellier, a friend of Rabelais. Rondelet's great work is a painstaking investigation of the fishes of the Mediterranean.

The learning of the time was liable to express itself in the form of encyclopaedias. These were mostly little but compilation. An exception must be made, however, for that of Conrad Gesner (1516-65), the great Swiss naturalist. His history of animals in five folio volumes covers the topics of quadrupeds, birds, fishes and snakes. Most of the matter is borrowed, but much also is original, notably the section on fishes which contains also figures of a large number of invertebrates. The work of Gesner is regarded by many as the starting point of modern zoology. To his contemporaries, Gesner was best known as a botanist, but his most important botanical works were not published until 200 years after his death.

Towards the end of the 16th century, following on the stimulus of the revival of art, of the new interest in natural history and of the re-institution of scientific anatomical studies, all the important departments of biology—atomy, physiology, botany, zoology—were becoming differentiated and making considerable progress. These subjects were being taught especially in the universities of northern Italy. Nowhere were they prosecuted with greater energy and ability than at Padua, the old school of Vesalius. Of all the teachers of that school, Jerome Fabricius (1537-1619) of Aquapendente exercised most influence. Fabricius made extensive embryological investigations, and his works on the subject are the first to be illustrated with figures drawn from the object. He made many physiological researches. Thus he described the valves of the veins and was one of the first to give an accurate account of the structure of the eye. Other important Paduan teachers of the time were Realdo, Colombo, Sanctorio, Cesalpino and Casserio.

The Rebirth of the Physiological Study of Animals and Plants.—A remarkable pupil of Fabricius was the Englishman, William Harvey (1578-1657), the discoverer of the circulation of the blood. His work on that subject, published in 1628, gave the first rational explanation of the workings of the animal body. (See MEDICINE, HISTORY OF, and HARVEY, WILLIAM.) While Harvey was at work on the special researches which are associated with his name, optical instruments were being constructed which made it possible to examine the structure of animals more minutely. In 1610 the compound microscope was described by Galileo and through him passed into modern use. The first systematic investigation of living things with the new instrument was made by a group of young men who formed themselves into the first scientific society, under the name of the *Academy of the Lynx*, which usually met at Rome. The small company was accustomed to assemble at the house of its president, Prince Federigo Cesi, duke of Aquaparta. His early death in 1628 brought the academy to an end, and many of its works perished. We have, however, records of a few of its observations which are peculiarly interesting as the earliest for which the microscope was systematically employed. Prince Cesi himself worked on botanical topics and described and portrayed the spores of the fern. Other members of the academy applied themselves to animal forms and fine enlarged representations of the parts of the bee have come down to us from them.

With the collapse of the "Academy of the Lynx" systematic microscopical observation ceased for a generation. The microscopical work between 1628 and 1660 was desultory and of no great consequence. After that date, however, there arose a series of great microscopical observers who between them revolutionized the conception of the nature of living things. Of these "classical microscopists" two, Hooke and Grew, were English, two, Leeuwenhoek and Swammerdam, were Dutch, and one, Malpighi, was Italian. It is interesting to observe that the more important work of all of them, except Swammerdam, was published in England.

Marcello Malpighi (1628-94) supplemented Harvey's work by describing the capillary circulation which Harvey had not seen. Malpighi demonstrated it in the lung of the frog. He extended greatly the work of Fabricius and he especially investigated the early stages of the development of the embryo of the chick. He gave very accurate representations of the early stages, and notably he showed that in the embryo there are paired branches of the aorta which reunite. These correspond, as we now know, to the vessels in the gills of a fish. Malpighi, who had no evolutionary leanings, had no conception of the nature of these vessels, but his description of them is very good. The bulkiest of Malpighi's contributions are his writings on the anatomy of plants. He gave excellent representations of the cell walls of plants, and he established the broad outlines of the microscopic anatomy of the roots and stems of the higher plants.

In botanical anatomy even more accurate and systematic observations were made by Nehemiah Grew (1641-1712, *q.v.*). Grew placed the study of the anatomy of plants on a firm foundation. He is also remarkable for his statement as to the sexual character of flowers—an observation which he himself ascribes to Sir Thomas Milligan, Savilian professor of geometry at Oxford.

Jan Jacob Swammerdam (1637-80, *q.v.*) was perhaps, the most accurate and remarkable as he was the most mentally unstable and shortlived of the "classical microscopists." His first work, *A General History of Insects*, deals chiefly with the modes of transformation of insects and brings out well the different modes of development of the major groups of insects. The text and figures are equally good, and the book itself obtained popular recognition. The early onset of a state of mind not far from insanity prevented much further publication. His magnificent *Bible of Nature*, which is probably the finest collection of microscopical observations ever published, did not appear till long after his death. It is still in current use by naturalists.

Antony van Leeuwenhoek (1632-1723, *q.v.*) made the most impression on his contemporaries of all the "classical microscopists." He published an immense number of observations of a desultory kind, nearly all of them in the *Philosophical Transactions of the Royal Society*. These observations contain many shrewd judgments. Leeuwenhoek's portrayal of Bacteria in 1683 and of spermatozoa in 1677 are triumphs of observation with the optical means at his disposal. On several occasions he drew and described the structure of striated muscle. He investigated in his own peculiar fashion almost every department of animal and plant life. No one was more influential than Leeuwenhoek in drawing the attention of observers to the minute complexity and beauty of the structure of the animal body.

Of all the "classical microscopists" the most gifted was Robert Hooke (1635-1703). He was, however, only to a very limited extent a biologist. His important work, *Micrographia*, appeared in London in 1665. In it he has a figure of the microscopic structure of cork showing the boundaries of the cell walls. He refers to these as *cellulae*, and the word "cell" in our modern biological nomenclature is probably derived from him. He shows also the cells on the surface of the stinging nettle, and he has a good account of its stinging apparatus. An important botanical observation by him is on leaf fungus, the development of which is well shown. He also gives accounts of the development of a mould and of the structure of moss, and of experiments on the sensitive plant. He gives the first figures of a polyzoan, and remarkable delineations of the compound eye of an insect, and of the larvae of a gnat, besides two gigantic figures of a flea and of a louse.

The work of the "classical microscopists" stands somewhat apart from that of other investigators and forms a peculiarly isolated chapter in the history of biology.

Early Attempts to Classify Living Things.—In the work of the early naturalists, whether they were botanists or zoologists, or microscopists or anatomists or encyclopaedists, there was seldom any sustained attempt at systematic arrangement. The encyclopaedic naturalists, such as Gesner, arranged their material according to the obvious divisions of the animal kingdom, fishes, birds, reptiles and the like. Botany and zoology were still in a state of great disorder.

The first trace of any systematic arrangement of descriptions of plants in accordance with their structure is in the work of Matthias de l'Obel (1538-1616), a Dutchman who came to England in his youth and dedicated his first book (1570) to Queen Elizabeth. He was keeper of a botanic garden of an English peer and, later, botanist to James I. L'Obel attempted to group plants according to the form of their leaves. He succeeded fairly well with the grasses, less well with the monocotyledons and failed with the dicotyledons, with which he confused the ferns.

More promising was the suggestion of the botanist Andrea Cesalpino (1519-1603) of Padua and Pisa, who attempted to class plants according to their flowers and fruits. The scheme formed on this basis was by far the best of the kind that had yet appeared. A small part of it was absorbed into the influential work of Caspar Bauhin of Basle (1550-1624 *q.v.*). For the most part, however, it fell on sterile ground and was little noticed till the time of Linnaeus.

So far as general arrangement is concerned Bauhin was distinctly inferior to Cesalpino. He gives, however, descriptions of about 6,000 plants. The great merit of his book is that in it for the first time the species of plants are placed together in small definite groups or *genera*. The modern conception of genus and species is in fact Bauhin's more than that of anybody else, and he and not Linnaeus is the true introducer of the binomial nomenclature which since Linnaeus has been in universal use.

Important steps in the direction of a systematic arrangement of living things were made by the two friends John Ray (1627-1705) and Francis Willughby (1635-72). They formed a scheme for a systematic description of the whole organic world. Willughby was to undertake the animals, Ray the plants. Willughby died early and in the event Ray became the chief founder of the science of systematic biology. His early attempts on the flora of Cambridge and his treatise on birds were followed in 1682 by his important *New System of Plants*. In this he demonstrated the true nature of buds and used the divisions of flowering plants into dicotyledons and monocotyledons. He based his system largely upon the fruit, but also upon the leaf and other characteristics and especially, following Cesalpino, upon the flowers. In doing this he succeeded in disentangling a number of the larger groupings of plants now known as families. His work in botany was completed by his *Synopsis of British Plants* and followed up by a *Synopsis of Quadrupeds and Serpents* (1693). This contains the first truly systematic arrangement of animals. It is based upon the fingers and toes and teeth of the animals concerned.

The systematic study of living things begun by Bauhin and Ray was continued by the Swede, Linnaeus (1707-78), the greatest of the systematists. Linnaeus brought to bear upon his life-work an enormous acquaintance with living things, especially plants, gained in the field. His prodigious industry and power of systematic arrangement would alone have given him a high place among naturalists. He profited from all the best teachers of the day, visiting many parts of Europe, including Holland, France and England. He was a most inspiring teacher and had numerous pupils, one of whom accompanied the English explorer, Captain Cook, and was for many years resident in London. Linnaeus became a sort of biological dictator, and for a century after his time most of the biological work that was done in every country was in his spirit.

Linnaeus had a perfect passion for classification and succeeded in assigning to every known animal and plant a position in his system. This involved placing any specimen first in a class, then in an order, then in a genus, then in a species. The broad outline of his system of classification has remained, though its rigid framework has long ago been abandoned.

The chief service of Linnaeus to biology is his method—derived from Bauhin, and impressed upon his contemporaries—of arranging living things into genera and species, with his development of the "binomial" system. His system extended even to man, and he distinguished *Homo sapiens* from *Homo troglodites*. His *Systema Naturae* went into many editions, the most highly prized being the tenth, to which naturalists still refer when they speak of Linnaean genera and species.

Linnaeus held that species are constant and invariable, a view in which he differed from John Ray. He assumed that all the members of a species were descended from a single pair that had been originally created. He afterwards modified this view and came to hold that it was the genera, not the species, which had issued from the Godhead.

The Beginning of the Study of Comparative Anatomy and Physiology.—The first animal whose naked eye structure was adequately explored was man himself. The anatomy of man was placed upon a sound basis by Vesalius in his wonderful monograph of 1543. For certain organs of the body Vesalius had not any adequate access to human material. Thus his account of the eye and of the organ of voice are taken from the dog. He was aware of differences in structure between man and animals and he chose several opportunities in his work to adopt a comparative method. A similar device is invoked by Pierre Belon. During the 16th century several other observers made dissections of animals and compared them to man. None was more exact than Ruini, a lawyer of Bologna, who published his monograph on the horse in 1598.

As the 17th century advanced there were a number of workers who further extended comparative studies. Of these the classical microscopists were by far the most important; for the most part they worked upon invertebrates. Monographs on various vertebrates were also prepared, as for instance that on the chameleon by the Italian Francesco Redi, and that on the chimpanzee or "pygmy" by the Englishman Edward Tyson. Monographs on invertebrates were prepared by Malpighi on the silkworm, by Swammerdam on the may-fly, the bee and the snail, and by Leeuwenhoek on the development of the flea.

With the great movement initiated by the work of Harvey, something in the nature of comparative physiology became possible. Harvey's masterpiece is in fact in large part a comparative study of the circulation. Of comparative physiology there has never been a greater exponent than the English country parson, the Rev. Stephen Hales (1677-1761). Hales practically began the study of the functional activity of plants and his work was the most important in that department until the 19th century. He measured the amount of water taken in by the roots and given off by the leaves, comparing this with the amount of moisture in the earth and showing the relationship of the one to the other. He made calculations of the rate at which water rises in the stems, and he showed that this has a relation with the rate at which it enters by the roots and transpires through the leaves. He measured also the force of suction in wood and roots, that is to say, "root pressure." He sought to show that these actions of living plants might be explained as the result of their structure. His most important contribution for botanical physiology was perhaps his demonstration that the air contributes something to the building up of the substance of plants, and in this respect he may be said to have been the discoverer of carbon dioxide. Following this up, he showed that air enters the plant not only through leaves but also through the rind. His experiments and conclusions in the physiology of animals were as important as in that of plants. Here he showed that there is a pressure of the blood within the vessels which can be measured, and that it varies in different circumstances and differs in the arteries and the veins. He even estimated the rate of flow in the capillaries. It is specially characteristic of his work that in all his experiments he sought to give a quantitative expression to his results. In this sense Hales was among the first to adopt exact methods in biology.

The comparative attitude in combination with exact experiment in biology was peculiarly characteristic of the investigators of the 18th century and separates them from those of the previous period. None pursued the method with greater enthusiasm than that great surgeon, John Hunter (1728-1793. *q.v.*; see also MEDICINE, HISTORY OF). At the time of his death Hunter had anatomized over 500 species of animals, many of them a great many times, as well as a great number of species of plants. The general object of his work might be described as a systematic attempt to trace the different phases of life as exhibited in the structure of animals and plants. Both in precept and example Hunter was the

greatest influence in connection with the establishment of natural history museums, the subsequent development of which has followed lines very similar to those which he suggested.

Hitherto comparative studies had been the preoccupation of individual workers. Georges Cuvier (1769-1832), by means of his immensely powerful position, was able to establish a complete and organized school of comparative investigators which may be said to have continued to our own time. His influence was very stimulating to research, but it cannot be said that he invariably exerted his power with the greatest wisdom. He believed strongly in the fixity of species and thus opposed the views of Lamarck (1744-1829, *q.v.*) and of Etienne Geoffroy Saint-Hilaire (1772-1844). Nevertheless by the palaeontological school which he founded and which extended into every country, he did perhaps more than any other man to collect material on which the doctrine of the impermanence of species became formally founded in later times.

Cuvier's great work, *La Règne Animale*, has formed one of the main foundations for comparative studies even to our own time. Among the specific achievements of Cuvier was firstly the creation of the science of palaeontology, secondly the exploration of the anatomy of the group Mollusca, and thirdly his systematic treatment of the vast class of fishes. The tradition of Cuvier was carried to England by Richard Owen (1804-92), who afterwards became director of the British Museum of Natural History.

While Cuvier and his school led in the comparative study of structure, the comparative study of function which had been expounded by Hales was established on a firmer basis by the great German physiologist, Johannes Müller (1801-58). (*See MÜLLER, JOHANNES, and MEDICINE, HISTORY OF.*) The latter part of Müller's life was given mainly to zoological research, and there is hardly a group in the animal kingdom on the knowledge of which he has not left his mark. As a microscopist he worked out the anatomy of the glandular and cartilaginous tissues, and grouped the connective tissues. He thus prepared the way for the work of his pupil Schwann. Müller was a convinced vitalist and his "Doctrine of Specific Nerve Energy" remains one of the corner-stones of vitalistic theory.

The study of the palaeontology of plants came later than that of animals. A few fossil plants had been described by earlier naturalists. Toward the end of Cuvier's time several figures of plants from the coal measures had been published with the generic and specific names that they still bear. Not until 1831 was the technique of their examination sufficiently advanced for microscopic study.

The study of fossil botany began to be systematic in 1858 with the work of W. C. Williamson (1816-95) who demonstrated that in coal are to be found gigantic forms similar to the higher flowerless plants such as horse-tails, ferns and club moss. His results were long treated with neglect, but have at last earned more recognition. During the last 50 years the palaeontology of plants has come near to be on the same footing as that of animals.

Effects of Geographical Exploration in the Course of Biological Development.—From the end of the 15th century the western nations of Europe were sending forth expeditions east and west, and these brought home knowledge of the natural products of lands newly explored. Thus the idea that each region has its characteristic living things, implicit in ancient biology but forgotten during the middle ages, became gradually explicit. In the 18th century exploratory expeditions began the practice of carrying specially-trained naturalists and thus they enter the history of biology. The three voyages of Captain Cook (*q.v.*) form an era, not only in the history of geographic discovery, but also in the study of living things. Among the naturalists that Cook took with him were Joseph Banks (1743-1800, *q.v.*), D. C. Solander (1736-82) and the pupil of Linnaeus, Robert Brown (1773-1858, *q.v.*). These three were instrumental in exploring the flora and fauna in the Pacific.

An important voyage which covered the western as well as the eastern hemisphere was that of the "Beagle," which sailed in 1831 and carried the naturalist Charles Darwin (1809-82, *q.v.*) with it. Quite apart from the investigations and theories with which Dar-

win's name is especially associated, the voyage was important as making accessible a whole multitude of new forms and as establishing the doctrine of zoo-geographical and phyto-geographical regions.

By the middle of the 19th century exploration and survey had become recognized as an important duty of the British Admiralty. Many scientific expeditions were sent out by that body. Of these the most important was that of the "Challenger" which sailed in 1872. The features of this expedition were, firstly, the very careful examination of the depth and character of the seas and sea water whereby oceanography was established as a separate science; secondly, the large number of very inaccessible places visited, and thirdly, the magnificent scale on which the scientific results of the journey were published. The reports of the "Challenger" expedition are still in current use by naturalists. The influence of this expedition, coming as a culmination of a series of previous voyages of exploration, was to modify considerably the general view of the range and variety of living things, and to enable naturalists to form a picture of life in the ocean where the geographical regions are distributed vertically rather than horizontally.

Reproduction of Plants and Its Comparison to That of Animals.—One of the main gaps in biological thought was the great difference between the nature of animals and that of plants. Especially the mode of reproduction of plants seemed to separate them very widely from animal forms. Theophrastus, for instance, gives a list of the modes of plant reproduction without hinting at the essential nature of fertilization. It is on this account, perhaps, that there have arisen so many legends concerning the "loves of the plants" and vague ideas ascribing sex to these beings. We have already seen how the idea was adumbrated in antiquity, by Theophrastus, among others, and how in the 17th century Millington, through the mouth of Grew, actually suggested sexual characters in the parts of the flowers. The conception of sex in plants was, however, lucidly, consistently and accurately set forth, though in elementary fashion, towards the end of the 17th century by R. J. Camerarius (1665-1721). This remarkable observer pointed out that the sex theory could not be made to apply to flowerless plants. The doctrine of the sex of flowers was accepted by Linnaeus and incorporated in a mechanical way into his system. Linnaeus found the sexual parts of plants convenient for establishing his classification.

During the course of the 18th century several botanists succeeded in using the pollen of one species to fertilize the flowers of another species of plant. The existence of hybridization was recognized, and one writer, J. G. Koelreuter (1733-1806) of Carlsruhe, held that the main agent in the fertilization of flowers was the wind, but that some flowers fertilized themselves, and that in others insects played a part. With great acumen, moreover, he pointed out that in some plants, *e.g.*, the mistletoe, which did not lend themselves to pollination by the wind, and in which the flowers were of different sexes, the only way of pollination was by insects. Moreover, for this same plant he called attention to a matter that was later very successfully investigated by Charles Darwin, namely, the question of the distribution of seeds by birds. Thus, as he pointed out, the mistletoe depends upon two groups of animals, birds and insects, for its existence. The subject was taken up by several German workers, notably, by C. C. Sprengel (1750-1816) who, in his work *The Newly Revealed Mystery of Nature in the Structure and Fertilization of Flowers*, paid special attention to cases in which the sexual parts occurring on a single blossom matured at different periods (dichogamy).

Sprengel reached the conclusion that some flowers can only be fertilized by insects, that some are so constructed as to injure and even kill insects that serve them, and that yet other flowers are fertilized by wind. He observed that flowers belonging to the last class always produced large quantities of light pollen, whereas in the flowers of the other types pollen is relatively heavy. He demonstrated the relation of the nectary to the process of fertilization, and in general he sought to show that his principles explained all the course of flowers—position, size, smell, colour, form, date of flowering and the like.

The actual process of fertilization was first observed by the extremely acute and versatile Italian microscopist, G. B. Amici (1784-1860). In 1823 this remarkable naturalist, whose work has not been adequately noticed, working with the microscope which he had himself improved, saw the tube given off by the pollen grain and its contents perform streaming movements. In 1830 he actually followed the pollen tubes into the ovary and observed one find its way to the micropyle of each ovule. These observations were confirmed by Robert Brown and Schleiden, and finally in 1846 the process of fertilization in flowering plants was placed upon a firm and recognized basis by Amici himself. Thus the general character of the vital processes of plants was brought into relation with that of animals.

Metamorphoses and Alternation of Generations in Animals and Plants.—An obstacle to the conception of living things obeying general laws has always been the observation of the extreme changes that some forms undergo. Such "metamorphoses" were observed by the ancients and were the subject of exact study during the 17th century by Swammerdam and other naturalists. These observations were extended by many observers during the 18th century and notably by John Turberville Needham (1713-81).

In the early '40s Johannes Steenstrup (1813-97) of Copenhagen, described how certain animals, notably jellyfish and parasitic worms, produce offspring which at no time resemble their parents, but which, on the other hand, bring forth progeny similar to the grandparents. Instances of the alternation of generations, as this process was called, were rapidly accumulated by naturalists from a number of organisms belonging to different groups in the animal kingdom. The well-known and easily observed instance of such a curious cycle is in the common aphids of roses in which there is an alternation of parthenogenetic and sexual generations.

In 1851, a short time after the appearance of Steenstrup's volume, Charles Darwin published his first important monograph on a living group. In this work on the barnacle and allied organisms, he demonstrated that these creatures go through a very remarkable metamorphosis, being born as free-swimming forms similar to other Crustacea and subsequently settling down to fixed life in which they sometimes resemble the Mollusca, with which Cuvier had classed them.

Darwin, moreover, demonstrated the curious feature that while individuals of this group were normally hermaphrodite, yet from time to time forms appeared that were male only, and there was at such times true sexual generation.

The interpretation of these phenomena was, however, unsatisfactory and vague. The botanist, Karl Nägeli (1817-91) in the '40s made some advance in examining the prothallia of ferns, and observed their free-swimming spermatozoa. At last in 1850 Wilhelm Hofmeister (1824-77, *q.v.*) gave a consecutive account of the actual process of generation in the fern, having observed the whole process of development from a single cell into the prothallus. He saw how the prothallus matured specialized cells, which, after conjugation, gave rise to the more conspicuous and well known asexual form. In other words, he had demonstrated the process of alternation of generations in the fern. He went on to show that the mode of production of the embryo in the pines and their allies was in certain cases intermediate between that of flowering plants and that of the higher flowerless plants such as ferns. Thus, by the sixth decade of the 19th century, it was established that fertilization in flowerless plants consists in the blending together of the spermatozoid and the egg-cell, and that in certain flowerless plants, *e.g.*, the ferns, there is a definite alternation of generations.

Observations on the sexual character of plants, on the alternation of generations and on metamorphoses gave absorbing interest to the investigation of generation in general, and stimulated the study of embryology both of animals and plants. Indirectly, these studies led to the firmer establishment and wider application of the cell theory, and to the accumulation of data which were used by the founders of the evolutionary school.

The Establishment of the Cellular Nature of Animals and Plants.—The appearance of cell walls is to be seen in many

microscopic drawings of plant tissues made in the 17th century by the great classical microscopists. In the careful analysis made by these men there is distinction between the various tissues of the higher plants, although in making this distinction they knew nothing of the cell substance dwelling within the cell wall. Not until the 19th century was the actual living substance of the cell first observed, a feat achieved by Amici.

In some of the accounts of the microscopic appearance of the tissues of animals by the classical microscopists, cells had been vaguely distinguished, though much less definitely than in plants. During the 18th century little important microscopic work was done. At the beginning of the 19th century a brilliant French investigator, J. F. X. Bichat (1771-1802), perceiving that the different parts of the body such as bones, muscle, nerves, blood-vessels, cartilages, etc., had a different microscopic appearance, succeeded in analysing the microscopical appearance into 21 "tissues." Out of this discovery arose the study of histology, a word introduced by Richard Owen, and still in current use.

Between the 17th and early 19th centuries advances were made in the knowledge of uni-cellular organisms. *Vorticella* had been described in 1667, Bacteria in 1683, *Paramecium* in 1702 and *Amoeba* in 1755. Several monographs dealing with uni-cellular plants and animals had appeared, but no advance had been made in the proper appreciation of the real nature of these organisms. In 1833 Robert Brown in his investigations on plant fertilization had discussed the nucleus and found it a normal accompaniment of the cell, but had no clear idea of the nature either of cell or of nucleus. The modern doctrine of the cell theory was placed upon a secure footing in the work of M. J. Schleiden of Jena (1804-81) in 1838, and of Theodore Schwann (1810-82) in the years 1838-39. Schleiden observed the process of protoplasmic streaming in many cells, and he recognized the nucleus as an essential element. He made a curious blunder in holding that cells originated by budding from the surges of the nucleus.

The work of Schwann, who was a pupil of Johannes Müller, has a more modern appearance than that of Schleiden. He gives admirable figures of animal cells, and especially of those of cartilage. He traces the cells of these and of other tissues from their undifferentiated origins, and he shows how the ovum is itself a cell. Finally, he passes to a general statement as to the cellular origin of animals and plants. We may note that he introduced the word "metabolic." He did not, however, shake himself free from Schleiden's theory of the cell originating from the nucleus. The investigator who was instrumental in destroying this theory was Karl Nägeli (1817-91). The word "protoplasm" was introduced by Hugo von Mohl (1805-72) of Tübingen, in 1846, and the conception of this substance as the physical basis of life was the work of Max Schultze (1822-74).

With the final establishment of the cell theory, histology became a special science and was admirably developed by the Swiss Albrecht von Kolliker (1817-1905), a pupil of Johannes Müller. The subject of histology was extended into the department of disease by yet another pupil of Johannes Müller, Rudolf Virchow (1821-1902, *q.v.*).

Organic Evolution. The Origin of Species.—By most older writers, species are treated as fixed and definite—as though their characteristics had been made once and for all, and have never altered. Thus in the opinion of Linnaeus there are "as many species as issued in pairs from the hands of the Creator." Even Linnaeus, despite his systematic obsession, began to see that it is often very difficult to separate species one from another. He did not like to move from his original position of the fixity of species, and therefore he simply substituted the genus for the species as the original creation. He thus reached the conclusion that "all the species of one genus constituted at first one species."

There are a great many early naturalists who adumbrated more or less clearly the doctrine of the evolution of organic forms. Many antiquarian writers have applied themselves to excavating this conception from writings of antiquity, of the middle ages and of modern times. The first naturalist, however, who clearly set forth the idea of evolution as applied to existing living things was Buffon (1707-78).

Buffon's great scientific work, *Natural History, General and Particular*, appeared in 45 volumes, and its publication occupied 55 years, 1749 to 1804, being completed after his death by one of his assistants. It aimed at containing all scientific knowledge and was the first modern attempt of the kind. In various parts of his great work and in other works Buffon expressed himself differently on the subject of organic evolution; nevertheless, we can see that he was moving farther and farther from the position occupied by Linnaeus. He finally accepted definitely the conception that species alter in type from time to time, but that at each alteration they retain some marks of their previous type, as the pig, for instance, retains fingers now in disuse but formerly used. He thus came to the conclusion that many species are degenerate forms of others; that the ape, for instance, is a degraded man, and that the ass is a degraded horse.

Similar views were set forth even more clearly by Erasmus Darwin (1731-1802), the grandfather of Charles Darwin. Erasmus Darwin held that species change in course of time, and that these changes are due to influences that bear upon the individual from without. These changes he held to be passed on to the offspring, so that he was a believer in the inheritance of acquired characteristics, a conception which was further developed by his younger contemporary J. B. de M. Lamarck (1744-1829, *q.v.*), whose *Zoological Philosophy* appeared in 1809. Lamarck held that for living organisms there existed a "natural order." He thought that if all the species that exist were known, they would be found to form a long ladder or scale in which each would differ but little from the next. This linear view of the arrangement of species Lamarck inherited ultimately from Aristotle. The gaps that he could discern in the existing series he ascribed to the destruction of the intermediate links. These gaps he hoped would be filled in by palaeontological discovery.

Over and above such value as Lamarck gave to the conception of the evolution of species we owe to him one important step of permanent value. It was part of his scheme that the animal and the plant world must be continuous with each other at some stage or stages. He set in sharp contrast the study of living things against that of non-living things. For the scientific study of the former, he adopted from Treviranus the word *biology* (1802). We thus owe this word *biology* largely to Lamarck, but still more we owe to Lamarck the conception of *biology* as a comprehensive study. Since according to Lamarck species shade into each other, it seemed to him improbable that they were permanently fixed. In reaching this conclusion, he laid much stress, as did Charles Darwin after him, on the peculiar development of domesticated animals. There must, he thought, be some agent acting to produce variations from the original type. This agent Lamarck believed to be environment. He thus reached the conclusions, firstly, that species vary under changing external influences; secondly, that there is a fundamental unity underlying the diversity of many things and thirdly, that the diversity of living things is subject to a progressive development. The mechanism of that development Lamarck held to be use and disuse of acquired characters.

Discussion of the conception of the progressive development of living things with its corollary, the inconstancy of species, was raised by many writers in the first half of the 19th century, among them the French naturalist Étienne Geoffroy Saint-Hilaire (1772-1844), and the German poet Goethe (1749-1832). In England the writer who attracted the most attention was the Rev. T. R. Malthus (1766-1834), whose important *Essay on Population* was first published anonymously in 1798. That work appeared during the French Revolution, and its tone and argument are not unrelated to the social views of the time—views which had their influence upon Darwin. Indeed, it is not too much to say that the *Origin of Species* is one of the secondary products of the utilitarian philosophy of which the chief exponent was Jeremy Bentham.

The treatise on the *Origin of Species* by Charles Darwin appeared early in 1859. For the detailed nature of the views there expressed, the reader is referred elsewhere (*see* DARWIN, CHARLES). It created a revolution in thought in England, and to a less extent in France and Germany. The cause of that change in opinion was not so much the doctrine of the impermanence of

species, which had been voiced by many before Darwin, as the fact that Darwin displayed to his readers the details of a process which could be seen in daily operation. Moreover, in setting forth his hypothesis of the action of natural selection he placed before his public a mechanism which he believed, and they believed, was sufficient to account for the process in question. His theory appealed specially to the practical minds of the English naturalists, who required an explanation of the process before they would altogether accept it. The theory naturally had less effect upon certain more philosophic thinkers, whom the actual evidence for the existence of evolution had already convinced.

In 1852, seven years before the publication of the *Origin of Species*, the philosopher Herbert Spencer (1820-1902) had set forth doctrines of evolution in which that word was probably used for the first time in literature to describe the idea of a general process of production of higher from lower forms. Sir Charles Lyell, of whom Darwin professed himself a disciple, and who deeply influenced his whole thought and work, used the word some 20 years earlier in a similar, though less general, sense. The word *evolution* was seldom used by Darwin himself, but the particular application that had been given to it by Spencer rapidly caught on, and Darwinism and Evolution were often treated as synonymous terms. The doctrines of Darwin, however, only applied and were only meant to apply to the world of life, nor even there can we regard the words Darwinism and Evolution as truly synonymous, for it is quite possible to conceive of organic evolution that is independent of such "Darwinian" factors as natural selection or sexual selection. The phrase "survival of the fittest" was also coined by Spencer, and caught on in the same way as did evolution. Evolutionary doctrines were diffused by a host of expert biologists who were rapidly converted to the Darwinian point of view. Among them T. H. Huxley (1825-95, *q.v.*) in England and Ernst Haeckel (1834-1919, *q.v.*) in Germany are worthy of special commemoration.

Since Darwin's time, and especially in the 20th century, a great deal of doubt has been cast on the evolutionary efficacy of those factors on which Darwin himself laid most stress. The conclusion that species do in fact give rise to other species has earned almost universal acceptance, and on the general relation of living things within the larger groups there is no wide divergence of opinion. Here Darwin may be regarded as victorious all along the line. It cannot be said, however, that any general agreement has been reached as to the process by which the great variation in living things has been produced, nor can it be claimed that there is any consensus of opinion as to the relationship of the main groups of living things with each other.

Despite these reservations it cannot be gainsaid that the history of biology since the days of Darwin may be treated as in large part a commentary on his work. The stimulus which he gave to comparative morphology has given rise to an almost incredible mass of literature dealing with plant and animal forms. His work has acted as a less stimulating influence on those departments which deal with function, and comparative physiology remains in a rudimentary state. The study of inheritance and of genetic characters, however, may be traced back directly to his example. A large part of the work of the last half century in this direction has been done in confirmation or refutation of the views which he expressed.

Biogenesis Versus Abiogenesis. The Origin of Life.—All the older naturalists, following Aristotle and his pupil Theophrastus, were willing to accept spontaneous generation at least of the lower forms of life. According to them, spontaneous generation was the normal mode of production of certain organisms. These views were universally accepted until the middle of the 17th century, and the advent of microscopic research.

The exploration of microscopic life soon revealed that many cases of apparent spontaneous generation had been falsely interpreted. Thus, for instance, Malpighi showed that galls were not spontaneously generated, but were associated with the larvae of the insect, the egg of which was placed within the plant by the parent insect. On the other hand, the increasing power of the microscope revealed the existence of more and more minute organ-

isms which seemed to appear out of nothing. Thus Leeuwenhoek saw such organisms in infusions of broth and other substances. Such infusions, at first perfectly clear, became in a few days turbid with these minute actively moving bodies, which were for this reason called Infusoria.

The first scientific treatment of the question of spontaneous generation was made by the Italian Francesco Redi (1626-97). This remarkable naturalist's experiments were most admirably designed, and his conclusions were lucidly set forth. He exposed fresh meat in jars covered with fine gauze, using as controls meat in other jars not so covered. Soon in the open jars larvae of flies developed, while eggs corresponding to such larvae were deposited on the surface of the gauze above the closed jars, but no larvae ever developed within the closed jar itself. Redi traced the larvae to their parents and showed conclusively that the generation of these insects could only be through parent forms.

With the extension of microscopic observation, however, the problem was thrown farther and farther back, and during the 18th century the battle on the subject of spontaneous generation raged back and forth. On the one hand it was shown that by boiling or chemically treating a medium, organisms appeared in it slowly or not at all. On the other hand, cases were always being adduced in which microscopic organisms did so appear, despite all precautions. About the middle of the 18th century the controversy reached an important stage in a discussion between John Turberville Needham (1713-81) and the versatile Abbé Spallanzani (1729-99). This discussion is interesting since it was practically repeated about 100 years later between Pasteur and his opponents. In 1748 Needham published what was in effect a repetition—made in conjunction with Buffon—of the experiments of Redi of the previous century. His experiments were, however, more refined than those of Redi, since he aimed at excluding even the most microscopic organisms. He came to the opposite conclusions to those of Redi, and inferred that microscopic organisms are generated spontaneously in organic substances. His apparatus consisted in effect of a phial filled with broth, the mouth of which was closed with mastic after the broth had been boiled. Needham's observations were good, but his deductions obscure, often verging on the mystical. He was effectively answered by Spallanzani, an investigator and writer of very great ability, who made important contributions to several branches of biological science. Some of Spallanzani's experiments to test the truth of spontaneous generation were so exactly like those of Pasteur in the last century that the figures of Pasteur might be used to illustrate the memoirs of his predecessor.

The controversy concerning spontaneous generation continued in much the same state until 1859. During the previous years Pasteur had shown that putrefactive and fermentative changes in organic substances and especially in fluids were due to organisms. The question was as to the origin of the organisms. He was well aware of the controversy between Needham and Spallanzani, but took the side of Spallanzani. By 1859, the year of the publication of *The Origin of Species*, Pasteur was engaged in acute controversy as to the origin of life. The matter was brought finally to a head by a very fine series of studies on the subject of spontaneous generation, the results of which Pasteur published in 1861.

Spallanzani, in his experiments, had heated phials, and he showed them containing putrescible substances. He was able to show that the contents of such phials remained indefinitely without any sign of putrefaction or fermentation. These processes did not take place unless or until the phial was opened. The only effective criticism made on the experiments of Spallanzani was that by the process of heating he had altered not only the infusions themselves but also the air contained within the phial. To this Pasteur had his answer, and it was the most triumphant of his experiments. He introduced into a flask an infusion of fermentable fluid. The neck was then drawn out into a long S shape, narrowed, but left open. The flask and its contents were then raised to boiling point repeatedly, and finally left at rest. The flask was left for days, weeks, months, undisturbed, and no fermentation took place. Finally, the neck was severed, thus exposing the fluid to the fall of atmospheric dust. In a few hours the liquid began

to ferment, and organisms could be demonstrated under the microscope.

This is the critical experiment in a demonstration that there is no such thing, under present terrestrial conditions, as biogenesis. The issue has been raised in various forms at various times and by various observers, but experiments comparable to those of Pasteur have always been devised in rebuttal. So far as any biological doctrine can be said to be firmly established, it is the doctrine that all living things are the product of living things. It is manifest that this doctrine does not prejudice the question as to the first origin of life, nor does it prejudice the question as to whether life may have arisen at more than one date and in more than one place. It does, however, give to the biologist a conception of the nature of life comparable in its value as a standard of scientific research to the doctrine of the conservation of matter and of energy in the hands of the physicist. By a chance, the movements which led to this demonstration on the origin of life were almost exactly contemporaneous with the movement which led to the establishment of the doctrine of organic evolution. Thus the modern period of biology may be said to open in our era about the year 1860.

Change in the Biological Outlook to the Modern Stage.—

The whole outlook on the nature of living things underwent a complete and profound change in the period of about 20 years following 1860. This change may be ascribed to a variety of causes, some of which we have been able to discuss. These we may now review categorically.

(a) The discovery of the essential identity in the mode of reproduction of animals and of plants.

(b) The discovery of the essential identity in the living substance of animals and of plants, and the emergence of the conception of protoplasm.

(c) The examination of methods of nutrition and of respiration, and the realization that these too are fundamentally the same for all living things.

(d) At first the differences of the food supply of animals and of plants seemed an insuperable barrier to this last step. Gradually, however, there emerged the conception of the chlorophyll apparatus concerned with the manufacture of organic substance for nutrition of both animal and plant. The elaboration within the plant body, from atmospheric gases, of material for absorption into tissue came to be recognized as part of the mechanism of living nature as a whole. The view of the "balance of life" and of organic nature as one huge mechanism came to the fore.

(e) The reduction of all living processes to terms of the cell.

(f) An evolutionary view of life gave a new conception of what may perhaps be called the "economics of nature." Thus there arose the tendency to examine the manner of life and habits of living things involving also their relations to other forms of living things.

(g) The conviction that, so far as scientific experience extends, all living things are derived from living things and are not generated from not-living things.

The combination of these conclusions and tendencies has introduced so much alteration in the approach of biologists to the material with which they deal that we may speak of entering an entirely new era. During this new era much attention has been concentrated on genetics and the process of heredity. For long, under evolutionary influence, the subject of variation in animals and plants was intensively studied. It is, however, apparent that the real problem to be solved is why the offspring resembles, not why it differs from its parent. This is perhaps the main modern biological problem. It may be observed that Aristotle, the first biologist, most clearly visualized this very problem. In this connection we may ascribe to Aristotle a most remarkable insight in his contention that the male contributes form only to the offspring and that nothing material need pass from male to female.

The study of Aristotle's expression of his views on this and allied topics will convince the investigator that throughout his writings he is in the presence of something far different from one of those cases of lucky prevision that are of frequent occurrence in the course of scientific development. A careful study of the

texts of Aristotle and of the history of biology reveals him as one of the very greatest and most profound of all biologists. From his writings and from the thoughts enshrined therein, biologists will ever return with refreshment and stimulus. Biological science in its most modern dress has indeed begun to tread again the Aristotelian path. The different fragments into which biology has been rent, morphology, physiology, genetics, embryology, ecology, cannot concern themselves with living things as they are but only with abstractions and ideas of what parts of them are or might be. The great master of those who know sought in antiquity to set forth a science of life as a whole. The greatest of his modern disciples had still the same objective when he wrote *The Origin of Species* 2,200 years later. It may be that this aspiration toward a unified biology, a true science of life, is the real legacy of Aristotle and Darwin.

BIOLOGY, ECONOMIC, the application of biological science to the control and improvement of man's practical interrelations with plants and animals. Man's circle of practical interests intersects the life-circles of many other creatures. There are, first, those wild animals that are captured for food, and it is the business of economic zoology to make the most of such creatures as deer and antelopes, rabbits and hares, pigeons and partridges, frogs and food-fishes, squids and snails, cockles and mussels, oysters and clams, crabs and lobsters, shrimps and prawns, palolo-worms and sea-cucumbers. Second, there are those animals captured, not for the food furnished directly by their flesh, but for other products, which are sometimes edible. Here are included baleen whales, elephants, beavers, birds of fine plumage, crocodiles for leather and turtles for combs, inedible fishes for glue and manure, oysters for pearls and beetles for blisters. Third, there are the animals that man has domesticated because of their direct or indirect utility—such as dog and horse, sheep and cattle, goats and reindeer, pigeons and poultry, ostriches and pheasants, silkworms and honey-bees. Here the modern biologist has to advise about the improvement of breeds.

Fourth, there are the animals that favour man's operations, like the earthworms that have made the fertile soil, and the flower-visiting insects that secure cross-pollination. Here the main service of the economic biologist is to disclose and appreciate vital linkages that bind living creatures into an intricate system. Fifth, there are man's animal enemies, reduced in modern times both in numbers and size. Most of the beasts of prey have ceased to be important, but the poisonous serpent still bites man's heel. Of greater moment are man's parasites, such as hookworm and bilharzia, and the vehicles of parasites such as the malaria-carrying mosquito and the sleeping-sickness-carrying tsetse fly. The biologist has to unravel life-histories and discover checks and how best they may be put into practice.

The sixth group is composed of animals which injure man indirectly by attacking organisms that are useful to him, notably his animal stock and his crops. The list includes voles, wood-pigeons, worm-parasites, locusts, cockchafer and cotton-weevils, wheat-midges and warble-flies. It is part of the task of the economic zoologist to combat these injurious animals, both directly and by encouraging natural checks. He has also to advise against operations that upset the balance of Nature and against careless importations and transportations. Seventh, there are animal enemies which injure man neither directly, nor through his stock and crops, but by getting at his stores or permanent products. Termites are very destructive in warm countries; rats and mice spoil much more than they eat; weevils and their relatives destroy stored corn; boring beetles eat away the rafters; shipworms and boring crustaceans do much harm to wooden piers.

An eighth group consists of animals that are man's indirect friends, by keeping a check on the fifth, sixth and seventh groups, and must therefore be conserved and encouraged. The birds of prey keep down the voles; the hedgehogs devour slugs; lapwings feed on wireworms and leather-jackets; ichneumon-flies lay their eggs in caterpillars; spiders catch scale-insects; lady-birds levy toll on the green-flies; water-wagtails are fond of the small water-snails that harbour the larval stages of the liver-fluke; and so on.

Similarly for plants, there are wild species directly used for food and drink; those that furnish valuable products like textiles and drugs; those that have been cultivated; those that help man, as forests do in improving the climate. On the other hand, there are inimical plants like the "poison-ivy" and many bacteria; the weeds that become pests and the moulds that attack crops; the fungi that destroy stores and dry-rot wood.

The central idea of economic biology is that the circle of human life intersects many other circles; and these intersections, which are often changing, have to be controlled in man's interests—generously and far-sightedly interpreted. Man is part of a web of life in the weaving of which he increasingly shares, and the success of his weaving depends on his understanding, which in this particular case is expressed in economic biology. BIOMETRY, a word to which three somewhat different meanings may be given. (a) Just as the word geometry, originally denoting land-measurement, has come to refer strictly to the mathematical study of the properties of space, so biometry may be taken to mean the mathematical study of the properties of populations, a subject otherwise designated as mathematical, or theoretical, statistics. This meaning, though too limited, gains in appropriateness from the fact that many of the great modern advances in statistical theory have in fact been developed in the study of biological material. (b) A more comprehensive meaning would include not only the mathematical theory but the experimental technique of, and the results obtained by, the application of quantitative methods in biology. This meaning will be adopted with the reservation that, since biological researches of all kinds, as they become more exact and detailed, must also become quantitative in character, we may ignore the large class of researches into living or organic materials, by quantitative physical or chemical methods, which do not involve the peculiar characteristics of populations, as opposed to individuals, or require statistical methods in their interpretation. (c) The third meaning is of historical interest only. In the early years of the 20th century the term was applied to the work of a group of investigators who held that heredity could better be studied by mass

BIOMETRICAL TABLE INDICATING VARIATIONS IN CHEST GIRTH AMONG 1126 ARMY RECRUITS

The observations of biometry are expressed in histograms, such as here shown, in which both the variation and frequency of certain common measurements, or data, may be compared at a glance. These tables may be constructed to illustrate the frequency of mental and moral qualities as well as physical measurements. The above histogram shows the frequency with which chest measurements, of 33 to 35 inches, were found among recruits of 18 years, and the rarity of the extreme measurements, whether very large or very small. A normal curve is superimposed

observations and correlation coefficients than by Mendelian analysis, by means of the frequency ratios obtained by experimental breeding. The progress of research has cleared away the causes of this controversy, and Mendel is now recognized as a pioneer in the introduction of statistical methods in biology.

rence in each such class may be observed, and the *frequency distribution* so obtained affords an adequate description of the particular variate in question. For example, the table below gives the measurement of chest girth for 1,126 recruits aged 18, obtained by No. 1 medical board at Liverpool:—

Chest girth (inches)	28	29	30	31	32	33	34	35	36	37	38	39	Total
Frequency	1	2	9	47	159	207	280	219	127	49	22	4	1,126

In treating so large a subject in a limited space it will be necessary to omit on the one hand the advanced mathematical development of statistical theory, and on the other the description of the innumerable practical applications of the systematic measurement of living things, ranging as these do from the mass production of clothing to the practical improvement of livestock. Attention will therefore be concentrated upon illustrating the fundamental arguments and methods of procedure by which progress has actually been achieved.

The primary purpose of biometrical methods is to overcome the obstacles to exact reasoning which arise from the variability of biological material. This is invariably accomplished by studying the frequency of occurrence of the different possible forms, or of the different possible types of response to treatment, etc. This method is at its simplest when there are only a few or even two possibilities to be enumerated, as when live births are classified as those of male or female children. The statement that 51% of such births are of males is thus of the biometrical type at its simplest, in that it expresses the frequency ratio of one possibility of a variable event. Mendel's discovery of the laws of inheritance was due to the fact that in matings from which the offspring could be of two or more distinct kinds, he took the revolutionary step of ascertaining from a sufficiently large count just what the frequency ratios actually were. In this way he found the simple ratios 1:1 and 3:1 characteristic of differences dependent upon only a single factor, in addition to the more complex ratios appropriate to two or more independent factors. The Mendelian method of studying heredity lay in the experimental determination and interpretation of frequency ratios, and it is noticeable that each great advance from Mendel's position has been achieved by the same method.

More often the biological variation observed cannot be described in terms of a few distinct classes. A quantity (technically a *variate*) such as human stature can take any exact quantitative value in a considerable range of variation. Such measurements may be grouped in artificial classes; e.g., all statures from 65½ to 66½ in. may be considered as one class. The frequency of occur-

The recognition of the value of such frequency distributions was principally due to Francis Galton. They are now invariably employed as a first step in the study of any biological phenomenon showing so-called continuous variation. The kind of information they provide may be seen at once by constructing a *frequency histogram*, in which the different measurements in the range of variation are indicated on a horizontal scale, and the classes are represented by rectangles, the areas of which are proportional to the number of individuals in each class.

The histogram illustrates graphically the high frequency with which measurements are recorded in the central classes of 33 to 35 in., and the increasing rarity with which the more extreme measurements occur, whether of very large or of very narrow chests. It is easy to see that the most frequently occurring chest girth (the *mode*) will be nearly the average or *mean* girth, and that these will both be near a third value, the *median*, which divides the population into two equal portions, half being larger than the median and half smaller. Further, the form of the histogram evidently gives a good idea of how variable the population is, for the same area might have been more concentrated than it is in the central values, and spaced over a smaller number of classes, representing a less variable population. Or, on the contrary, it might have had a lower central hump, and be spaced over a wider range, if the population had been more variable.

The statistical treatment of frequency distributions is much facilitated by the fact that, in a large number of cases, the observed distributions conform, at least, to a good approximation to a definite mathematical form known as the normal distribution. This is specified by the law that the logarithm of the frequency in an infinitesimal range of the variate is a quadratic function of the variate itself. The variable part of this function may be written as $\frac{(x-m)^2}{2\sigma^2}$ in which m designates the central point, or mean, of the symmetrical distribution, and σ^2 designates the *variance* of the distribution, and provides a quantitative measure of the amount of variation present; its square root, σ , is called the standard deviation of the distribution.

From any sample of observations it is important, therefore, to obtain estimates of the two parameters m and σ which specify the population sampled; such an estimate has been termed a *statistic*. It has been demonstrated that the best obtainable estimate of the quantity m is found by calculating the arithmetic mean of the observations, written $\bar{x} = \frac{1}{n} \sum S(x)$ where n is the number of observations in the sample and \sum denotes summation over all the observations. The best estimate of the variance may then be written $s^2 = \frac{1}{n-1} \sum S(x-x)^2$.

When these two statistics have been calculated, the corresponding curve of frequency distribution may be constructed, as is shown in the figure by the dotted curve superimposed on the histogram. It will be seen that this process has removed the two arbitrary and fortuitous elements in the original representations; (a) the discontinuities, introduced by our arbitrary choice of units of measurement and grouping, are replaced by a curve showing continuous variation of frequency; (b) variations, due to the chances of random sampling, of the numbers in the different classes, are obliterated except in so far as the estimates of m and σ have been influenced by these errors of random sampling.

The errors to which statistical estimates are liable form the branch of the subject to which the greatest amount of attention has been given in recent years. For samples from the normal distribution it is known that the error distribution of the mean, \bar{x} , is itself normal, with variance equal to $\frac{1}{n}\sigma^2$; the distribution of s (the standard deviation estimated from the sample) is not normal, but is known with exactitude, and for large samples it approximates to the normal form with variance equal to $\frac{1}{2n}\sigma^2$. Using

our estimate s for the value of σ , these variances and the corresponding standard errors may be regarded as known; thus having a mean chest girth of 34".009, with an estimated standard error 0".0443, we have reason for some confidence that the mean girth of the population sampled lies between the limits 33".920 and 34".198. The result may be expressed otherwise by saying that the mean chest girth is *significantly* greater than 33".92, i.e., it exceeds this quantity by an amount which cannot readily be ascribed to chance.

It will be noted that although the measurements are actually taken only to the nearest inch it is improbable that the estimate of the mean will be in error by as much as $\frac{1}{10}$ of an inch, and its standard error may be diminished without limit by taking larger samples. This important fact depends on the positive and negative errors of measurement neutralizing each other more and more exactly as the number in the sample is increased; it would not be true if the graduations of the tape measure used were in error. Similarly, in estimating the variance of the population, an allowance (Sheppard's correction) is usually made for the variance introduced by taking the measurements only to the nearest inch; if, however, owing to careless measuring a proportion of cases are not measured truly to the nearest inch, this proportion being greatest when the true measurement is near a class boundary, a part of the variation observed will be really due to these additional errors of measurement. In order to be sure that these errors are sufficiently rare the precaution should be taken of obtaining duplicate measurements, on different occasions, of a number of individuals.

The methods outlined above find a very wide application in the study of the *correlation* or *covariation* of two or more variates. For this purpose a two-way frequency distribution is used which expresses, as the result of direct enumeration, how frequently both of the variates shall simultaneously have values between assigned limits. The utility of this method lies in the great choice which exists in the pair of variates chosen. Thus, if we have the height and weight of each of a number of individuals, a two-way distribution will show how frequently an individual chosen at random will have any given combination of height and weight; how frequently an individual of given weight will have an assigned

height; and how frequently an individual of given height will have an assigned weight. Definite mathematical relations (regression equations) will be found to express the average weight of persons of a given height in terms of that height, or the average height of persons of a given weight in terms of that weight. Finally, it is sometimes useful to evaluate an abstract number, the correlation coefficient, which measures on an arbitrary quantitative scale the closeness of the interrelation between the two varieties.

Again, the two variates may be similar measurements of related persons, such as are the heights of parent and child. The regression equation, which expresses the average height of the child in terms of the height of the chosen parent, is then of great importance, for it provides a direct measure of the efficacy of selection, natural or artificial, in modifying the average character of the population. For human physical measurements the simple rule is found to hold that, if one parent only is selected to be one unit above the average, then the next generation will have advanced by half a unit; but if both parents are selected the advance is approximately $\frac{2}{3}$ of a unit. Similar biometrical studies are increasingly important in the improvement of livestock. In cases of inheritance the correlation coefficient may be used as a measure of the heritability of the character in question, as when it is found that certain mental and moral qualities are associated in near relatives to just the same extent as are physical measurements. Alternatively it may be taken to measure the closeness of relationship, as when it is shown that twins of like sex are more closely alike than are ordinary brothers or sisters.

The study of simultaneous distributions has opened out an immense field of research by providing a precise and objective method of studying vague and ill-understood influences—for example, meteorological and sociological. It is essentially a pioneer method, and is usually replaced as soon as exact knowledge is available of the causes at work. Pairs of values may be associated for innumerable reasons, but the first step, which the two-way table provides, is to find if they are or are not in fact associated.

In most cases there is a wide choice in the statistics which might be calculated as estimates of the parameters characteristic of the population. These will differ greatly in the efficiency with which they utilize the information supplied by the data. Methods are, however, available for obtaining in any particular case statistics which shall be efficient in this respect.

As further exact solutions are obtained of the error distribution of different statistics, so accurate tests of significance appropriate to the different problems which arise in practice are being developed. For a single normally distributed variate it is possible to test accurately whether the mean and variance do or do not differ significantly from given hypothetical values, as also whether two means or two variances obtained from observations are or are not in agreement. For the simultaneous distributions of two or more variates the theory of the regression coefficients and of the coefficient of correlation, in terms of which the dependence of one variate upon another may be expressed, is now almost equally complete. In addition, tests of *goodness of fit* are available for comparing the frequency of occurrence of the different classes with the frequencies expected by hypothesis, and for testing the adequacy of regression formulae, linear or non-linear, involving one or more independent variates. These tests may all be developed in the form known as the analysis of variance. Although much further mathematical research is required before the practical needs of biologists in this field will be fully met, the methods already established are adequate for a very large number of purposes, not the least of which is the increased precision and efficiency in the design of biological experiments.

Fisher, *Statistical Methods for Research Workers* (1925), primarily for biologists, with special attention to exact tests of significance, and the treatment of small samples; Pearl, *Introduction to Medical Biometry and Statistics* (1923); G. U. Yule, *An Introduction to the Theory of Statistics* (1927); *Recommendations for the taking and presentation of biological measurements* (British Association, 1927), practical recommendations of a joint committee of biologists and statisticians; *Biometrika*, a journal for the statistical study of biological problems, ed. K. Pearson. (R. A. F.)

BION, Greek bucolic poet, was born at Phlossa, near Smyrna, and flourished somewhere about 100 B.C. Nothing is known of him, except that he probably lived in Sicily. The story that he died of poison is probably only an invention of the author of the *Epitaphios Bionos* (see MOSCHUS). Although his poems are called *Bucolics* the remains show little of the vigour and truthfulness to nature characteristic of Theocritus. They are over-sentimental, and show the overstrained reflection which characterizes late pastoral poetry. The longest and best of them is the *Lament for Adonis* ('Επιτάφιος Ἀδωνίδος) which refers to the first day of the festival, when the death of Adonis was lamented. Fragments of his other pieces are preserved in Stobaeus; the epithalamium of Achilles and Deidameia is not his.

Bion and Moschus have been edited separately by G. Hermann (1849) and C. Ziegler (Tübingen, 1869), the *Epitaphios Adonidos* by H. L. Ahrens (1854) and E. Hiller in *Beiträge zur Textgeschichte der griechischen Bukoliker* (1888). Bion's poems are generally included in the editions of Theocritus. English transl.: J. Banks (1853) in Bohn's *Classical Library*; Andrew Lang (1889), with Theocritus and Moschus (prose); A. S. Way (1913) (verse); edition by U. Wilamowitz-Möllerndorff in the *Oxford Scriptorum Classicorum Bibliotheca* (1905). On the date of Bion see F. Bücheler in *Rheinisches Museum*, xxx. pp. 33-41 (1875); W. Stein, *De Moschi et Bionis Aetate* (Tübingen, 1893); also G. Knaack in Pauly-Wissowa's *Realencyklopädie*, sv; and F. Susemihl, *Geschichte der griechischen Literatur in der Alexandrinerzeit*, i, p. 233 (1891).

BION, of Borysthenes (Olbia), in Sarmatia, Greek moralist and philosopher, flourished in the first half of the 3rd century B.C. He was of low origin and was sold as slave to a rhetorician, who gave him his freedom and made him his heir. After the death of his patron, Bion went to Athens to study philosophy. He was admitted to the literary circle at the court of Antigonus Gonatas. He subsequently taught philosophy at Rhodes and died at Chalcis in Euboea. His life was written by Diogenes Laërtius. Bion's *Diatribae* was a satire of a popular character; while praising poverty and philosophy, he attacked the gods, musicians, geometers, astrologers, and the wealthy. His influence is distinctly traceable in succeeding writers, e.g., in the satires of Menippus. Horace (*Epistles*, ii. 2, 60) alludes to his satires (*sal nigrum*). An idea of his writings can be gained from the fragments of Teles, a cynic philosopher of the 3rd century, who made great use of them. Specimens of his apophthegms may be found in Diogenes Laërtius and Stobaeus, while there are traces of his influence in Seneca.

See Hoogvliet, *De Vita, Doctrina, et Scriptis Bionis* (1821); Rosignol, *Fragmenta Bionis Borysthenitae* (1830); Heinze, *De Horatio Bionis Imitatore* (1889); von Arnim's article in Pauly-Wissowa.

BIONOMICS, the study of an organism in relation to its environment. See ZOOLOGY; ECOLOGY: *Animal*; PLANTS. *Ecology*.

BIOT, JEAN BAPTISTE (1774-1862), French physicist, was born in Paris on April 21, 1774. In 1800 he became professor of physics at the Collège de France, through the influence of Laplace, from whom he had sought and obtained the favour of reading the proof sheets of the *Mécanique céleste*. In 1804 he accompanied Gay Lussac on the first balloon ascent undertaken for scientific purposes. In 1806 he was associated with F. J. D. Arago, with whom he had already carried out investigations on the refractive properties of different gases, in the measurement of an arc of the meridian in Spain, and in subsequent years he was engaged in various other geodetic determinations. He died in Paris on Feb. 3, 1862. He was especially interested in questions relating to the polarization of light, and his observations in this field, which gained him the Rumford medal of the Royal Society in 1840, laid the foundations of the polarimetric analysis of sugar.

His very numerous published works include: *Analyse de la mécanique céleste de M. Laplace* (1801); *Traité analytique des courbes et des surfaces du second degré* (1802); *Recherches sur l'intégration des équations différentielles partielles et sur les vibrations des surfaces* (1803); *Traité de physique* (1816); *Recueil d'observations géodésiques, astronomiques et physiques exécutées en Espagne et Écosse*, with Arago (1821); *Mémoire sur la vraie constitution de l'atmosphère terrestre* (1841); *Recherches sur plusieurs points de l'astronomie égyptienne* (1823); *Recherches sur l'ancienne astronomie chinoise* (1840); *Études sur l'astronomie indienne et sur l'astronomie chinoise* (1862).

His son, EDOUARD CONSTANT BIOT (1803-1850), after amassing a competence from railway engineering, turned to the study of

Chinese subjects, and published *Causes de l'abolition de l'esclavage ancien en occident* (1840); *Dictionnaire des noms anciens et modernes des villes et des arrondissements compris dans l'empire chinois* (1842); *Essai sur l'histoire de l'instruction publique en Chine et de la corporation des lettres* (1847); *Mémoire sur les colonies militaires et agricoles des chinois* (1850).

BIOTITE, an important rock-forming mineral belonging to the group of micas (*q.v.*). The name was given in honour of the French physicist, J. B. Biot, who in 1816 found the magnesia-micas to be optically uniaxial or nearly so. The magnesia-micas are now referred to the species biotite and phlogopite, which differ in that the former contains a considerable but widely varying amount of iron. Biotite is an orthosilicate of aluminium, magnesium, ferrous and ferric iron, potassium and basic hydrogen, containing small amounts of calcium, sodium, lithium, fluorine, titanium, etc., and ranges in composition between $(\text{H,K})_2(\text{Mg,Fe})_4(\text{Al,Fe})_2(\text{SiO}_4)_4$ and $(\text{H,K})_2(\text{Mg,Fe})_2\text{Al}_2(\text{SiO}_4)_2$.

Like the other micas, it is monoclinic with pseudo-hexagonal symmetry, and possesses a perfect cleavage in one direction. Biotite is, however, readily distinguished by its darker colour, strong pleochroism, and small optic axial angle. The colour is usually brown or dark-green; thick crystals are often deep-black and opaque. The absorption of light-rays vibrating parallel to the cleavage is much greater than of rays vibrating in a direction perpendicular thereto, and in dark-coloured crystals the former are almost completely absorbed. The specific gravity of biotite is, as a rule, higher than that of other micas, varying from 2.7 to 3.1 according to the amount of iron present. The hardness is 2½ to 3.

Several varieties of biotite are distinguished. By G. Tschermak it is divided into two classes, *meroxene* and *anomite*; in the former the plane of the optic axes coincides with the plane of symmetry, whilst in the latter it is perpendicular thereto. Haughtonite and siderophyllite are black varieties rich in ferrous iron, and lepidomelane is a variety rich in ferric iron. Rubellane, hydrobiotite, pseudobiotite and others are altered forms of biotite.

Biotite is a common constituent of igneous and crystalline rocks. In granite, gneiss, and mica-schist it is often associated with muscovite (white mica), the two kinds having sometimes grown in parallel position. In volcanic rocks, and in nearly all other kinds of igneous rocks with the exception of granite, biotite occurs to the exclusion of the muscovite. In the dyke-rocks known as mica-traps or mica-lamprophyres biotite is especially abundant. It is also one of the most characteristic products of contact-metamorphism, being developed in sedimentary and other rocks at their contact with granite masses.

Although biotite (black mica) is much more common and widely distributed than white mica, yet it is of far less economic importance. The small size of the sheets, their brittleness and want of transparency render the material of little value. Large, cleavable masses yielding fine smoky-black and green sheets, sufficiently elastic for industrial purposes, are, however, found in Renfrew county, Ontario.

(L. J. S.)

BY COURTESY OF THE WRIGHT MFG. CO.
THE FORE-RUNNER, 1904. THE MACHINE IN WHICH THE WRIGHT BROTHERS MADE THEIR EARLIEST PRACTICAL FLIGHTS. HAVING NO WHEELS, IT HAD TO BE LAUNCHED FROM A SLIPWAY

The effective depth of the girder thus formed is the vertical distance between the planes, which is much greater than the depth of the wing itself. This enables the structure to be made light and stiff.

BIPLANE, a form of aeroplane (*q.v.*) in which the supporting surface is arranged in two planes one above the other. This is the most widely adopted arrangement, its only important competitor being the monoplane (*q.v.*). The chief advantages of a biplane are compactness and light weight of structure. Almost invariably the planes are braced together by struts and wires.

The resistance of the inter-plane bracing is appreciable, but for a given area and span of wing the biplane uses less power than a monoplane in developing a given lift, and on the balance there is little to choose between them on this account. The biplane is inevitably rather more complex and maintenance costs tend to be correspondingly greater, but design is steadily tending to the elimination of details requiring adjustment, and the

THE MODERN BIPLANE, A MACHINE WHICH HAS REVOLUTIONIZED WORLD TRAVEL

While the principle of flight remains the same as in the Wright Brothers' early model, a quarter of a century of progress has greatly altered the appearance of the machine

biplane will probably remain the predominating type. A typical biplane is shown in the figure and further examples will be found in the articles referred to above.

BIPONT EDITIONS, the name of a famous series of editions, in 50 volumes, of Greek and Latin classical authors, so called from Bipontium, the modern Latin name of Zweibrücken or Deux-Ponts in Bavaria, where they were first issued in 1779. Their place of publication was afterwards transferred to Strasbourg.

BIPRISM, FRESNEL'S, an obtuse angled prism used for the production of interference fringes. The prism is set up so that the line joining the obtuse angle to the source of light (in the form of a slit) is normal to the base, and the edge of the obtuse angle is parallel to the slit, this angle lying between the source and the base. Two virtual images of the source, very close together, are formed, and the biprism is thus equivalent to two mirrors inclined so that they produce interference. (See LIGHT.)

BIQUADRATIC, an adjective used in mathematics to refer to the fourth power of a quantity; that is, to the square of a square. It is used in connection with equations or algebraic functions. The equation $ax^4 + bx^3 + cx^2 + dx + e = 0$ is a biquadratic equation, since the highest power of the unknown quantity (x) is the fourth; that is, x^4 is the square of x^2 , or the square of the square of x (the *bi*, two + *quadratus*, square). The general biquadratic equation was first solved by Lodovico Ferrari (1522-c. 1560) and was published by Cardan in his *Ars Magna* (1545). Excepting in the above cases and in connection with a few geometric figures the word "quartic" is used instead of "biquadratic." (See EQUATIONS.)

BIRBHUM, a district of British India in the Burdwan division of Bengal, bounded on the south by the river Ajai. The administrative headquarters are at Suri (pop. 8,915). The district has an area of 1,753 sq. m. and a population (1921) of 847,570. The eastern portion is the ordinary alluvial plain of the Gangetic delta; the western part consists of undulating ridges of laterite. The Ajai, Bakheswar and Mor or Maurakshi, are the principal rivers. The chief industry is the spinning and weaving of silk, chiefly from tussur or jungle silk-worms.

Birbhum in the early part of the 13th century constituted a Hindu State, with its capital at Rajnagar or Nagar which was conquered by the Mohammedans. At the beginning of the 18th century it appears as a kind of military fief held under the nawab of Bengal by one Asadullah Khan. It passed into British possession in 1765, suffered terribly from the famine of 1770, and between 1785 and 1790 was a prey to armed bands of dacoits who found a refuge in the great jungle on the western border. Since that time (except during the Santal rising of 1855) the district has been peaceful and prosperous.

BIRCH, SAMUEL (1813-1885), English Egyptologist and

antiquary. At first employed in the Record Office, he was appointed to the British Museum staff in 1836, as he knew Chinese. He then began to study Egyptian and Assyrian, and on the reorganization of the museum he was in charge of the department of that name. He wrote a grammar of Egyptian hieroglyphs and compiled a dictionary, as well as making a translation of the *Book of the Dead*. He wrote a standard history of pottery and many philological papers.

BIRCH, THOMAS (1705-1766), English historian, son of Joseph Birch, was born at Clerkenwell on Nov. 23, 1705. He was ordained deacon in the Church of England in 1730 and priest in 1731. He held successively a number of benefices in different counties, and finally in London. Birch was killed on Jan. 9, 1766, by a fall from his horse. He left his books and manuscripts to the British Museum, and a sum of about £500 to increase the salaries of the three assistant librarians.

Birch had an enormous capacity for work. In spite of their dullness many of his works are of considerable value, although Horace Walpole questioned his "parts, taste and judgment." Many of his letters appear in *Literary Anecdotes of the 18th Century* (London, 1812-15) and *Illustrations of the Literary History of the 18th Century* (London, 1817-58); by J. Nichols, in the *Bibliotheca Topographica Britannica*, vol. iii. (London, 1780-90), and in Boswell's *Life of Johnson*.

For a list of his works see W. P. Courtney in the *Dictionary of National Biography*, vol. v. (1886); A. Kippis, *Biographia Britannica* (1778-93); Horace Walpole, *Letters* (1891).

BIRCH (*Betula*), a genus of plants allied to the alder (*Alnus*), and like it a member of the family Betulaceae. The various species of birch are mostly trees of medium size, but several of them are merely shrubs. They are as a rule of a very hardy character,

FROM STRASSBURGER, "LEHRBUCH DER BOTANIK"

THE BIRCH (*BETULA ALBA*), A USEFUL PLANT INDIGENOUS TO NORTHERN LATITUDES. IT IS EMPLOYED IN MAKING CANOES, BROOMS, FOR ROOFING HOUSES, ETC., AND IN RUSSIA THE PULVERIZED BARK IS EATEN

Branch with male and female catkins
A. Bract with three male flowers (enlarged)
B. Bract with three female flowers (enlarged)
C. Inflorescence in the fruiting condition

thriving best in northern latitudes—the trees having round, slender branches, and serrate, deciduous leaves, with barren and fertile catkins on the same tree, and winged fruits, the so-called seeds. The bark occurs in fine soft membranous layers, the outer cuticle of which peels off in thin, white, papery sheets.

The white or silver birch (*B. alba*) (see fig.) grows throughout the greater part of Europe, and also in Asia Minor, and Siberia, reaching in the north to the extreme limits of forest vegetation and stretching southward on the European continent as a forest

tree to 45° N. The male and female flowers are borne on separate catkins in April and May. It is a short-lived tree, generally from 40–50 ft. high with a trunk seldom more than 1 ft. in diameter. It flourishes in light soils and is one of the few trees that will grow amongst heather; owing to the large number of "winged seeds" which are readily scattered by the wind, it spreads rapidly, springing up where the soil is dry and covering clearings or waste places.

This birch is one of the most widespread and generally useful of forest trees of Russia, occurring in vast forests, either in pure stands or mixed with pines, poplars and other forest trees. The wood is highly valued by carriage-builders, upholsterers and turners on account of its toughness and tenacity, and in Russia it is prized as firewood and a source of charcoal. Its pliant and flexible branches are made into brooms; and in ancient Rome the fasces of the lictors, with which they cleared the way for the magistrates, were made up of birch rods. A similar use of birch rods has continued among pedagogues to times so recent that the birch is yet, literally or metaphorically, the instrument of school-room discipline. The bark of the white birch is much more durable, and industrially of greater value, than the wood. It is impermeable to water, and is used in northern countries for roofing, for domestic utensils, for boxes and jars to contain both solid and liquid substances, and for a kind of bark shoes worn by the Russian peasantry. By dry distillation the bark yields an empyreumatic oil, called *diogott* in Russia, used in the preparation of Russia leather; to this oil the peculiar pleasant odour of the leather is due. The bark itself is used in tanning; and by the Samoiedes and Kamchatkans it is ground up and eaten on account of the starchy matter it contains. A sugary sap is drawn from the trunk in the spring before the opening of the leaf-buds, and is fermented into a kind of beer and vinegar.

Of some 10 species which belong peculiarly to North America, the most important economically are the yellow birch (*B. lutea*), the sweet, black or cherry birch (*B. lenta*), the red or river birch (*B. nigra*), and the paper or canoe birch (*B. papyrifera*). The yellow birch, one of the largest deciduous trees of north-eastern America, with a trunk 3 ft. to 4 ft. in diameter and occasionally 100 ft. high, grows from Newfoundland to extreme western Ontario, and southward to central Iowa and North Carolina. It is cut for lumber chiefly in the Lake States and New York. The hard, close-grained wood, as heavy as that of red oak, is extensively used for furniture and interior finishings. The sweet, black or cherry birch, which sometimes grows to a height of 80 ft. with a trunk diameter of 2 ft. to 5 ft., has smooth, red-brown, cherry-like aromatic bark from which an oil very similar to the oil of wintergreen is extracted. It grows from Newfoundland to Iowa and southward to Florida, attaining its greatest size in the Appalachian mountains, West Virginia and Pennsylvania, usually yielding the largest cut of sweet birch lumber, often called cherry birch in the trade. The strong, hard yellowish-brown wood, as heavy as that of white oak, is highly valued for making furniture, agricultural implements and woodenware. The semi-aquatic red or river birch, 80 ft. to 90 ft. high and sometimes 5 ft. in diameter, with dark red branches, grows from Massachusetts to Nebraska and south to Florida and Texas. It attains its greatest size in warm, wet lowlands along the Gulf coast, where it is the only birch. The strong light brown wood, which is cut for lumber in the South, is used for furniture and in turnery.

The paper or canoe birch, very similar to the European white birch, grows from Newfoundland and Labrador to Alaska as far as 70° N., and southward to New York, Nebraska and Washington. It grows usually from 60 ft. to 70 ft. high with a trunk from 2 ft. to 3 ft. in diameter. Its creamy white, tough, durable bark, easily separable into layers, is used by the northern Indians for making canoes, drinking cups, dishes and baskets. The bark has also a limited use as a substitute for paper. The light, strong, close-grained wood is extensively utilized in turnery, especially for spools, shoe-last and shoe pegs, and also for wood pulp and fuel. From 1900 to 1920 the total birch lumber cut in the United States at times exceeded 400,000,000 bd. ft. annually, of which Wisconsin and Michigan usually contributed more than half.

BIRCH-PFEIFFER, CHARLOTTE (1800–1868), German actress and dramatic writer, was born at Stuttgart. She was trained at the Munich court theatre, and in 1818 began to play leading tragic rôles at various theatres. In 1825 she married the historian Christian Birch of Copenhagen, but continued to act. From 1837 to 1843 she managed the theatre at Zurich. In 1844 she accepted an engagement at the royal theatre in Berlin, to which she remained attached until her death. She dramatized many popular novels, and her plays, adapted and original, make 23 volumes, *Gesammelte dramatische Werke* (1863–80). Her novels and tales, *Gesammelte Novellen und Erzählungen*, were collected in three volumes (1863–65).

BIRD-LOUSE, any small flattened degenerate wingless insect of the suborder Mallophaga of the order Anoplura (see INSECTS) parasitic upon birds and mammals and living upon feathers, hair, and other epidermal products. Their biting mouth-parts serve to distinguish them from true lice of the suborder Siphunculata, in which the mouth-parts are suctorial (see LOUSE).

BIRDS. The apartness of birds (Aves) from other classes of animals is so conspicuous that they can be separated off by the two words "feathered bipeds." A little more content is given to the definition if two other terms be added—"warm-blooded" and "oviparous." But an attempt must be made to reach a more comprehensive diagnosis, and emphasis may be laid, first of all, on the intensity of the bird's life. The temperature of the body is higher than that of mammals, and the warm-bloodedness, or ability to sustain a uniform temperature, is almost perfect except in young nestlings. The high temperature is connected with the large proportion of muscle, the muscles of flight sometimes weighing about half the whole animal; and the conservation of heat is secured by the non-conducting plumage. The great advantage of a constant high temperature is that the essential chemical processes of the body (metabolism) go on more uniformly and rapidly. Intensity of life is also expressed in the rapid beating of the bird's heart, the quick breathing movements, the richness of the blood in the oxygen-carrying red corpuscles, and perhaps also in the perfection of the digestive processes, as inferred from the relatively small amount of faecal matter. As contrasted with the reptiles, from which they evolved, the ratio of katabolism to anabolism averages much higher.

With a spare muscular body, quick breathing, a strong heart, perfect digestion, rich blood, and a covering of feathers, it is natural to correlate great activity—in running, leaping, climbing, parachuting and eventually flying. The bipedal habit is perhaps ancestral, being indicated in extinct reptiles such as the *Pseudosuchia* and the *Ornithischia*, and this emancipation of the fore-limb from being a support opened up the possibility of a new function. The patagium, extending from the shoulder-joint along the pre-axial margin of the arm, hints at a webbed fore-limb, useful as a parachute in leaping, before a feathered wing had fully evolved. Antecedent to and also accessory to flight was the improvement in the circulatory system by the formation of the dorsal aorta out of a single systemic arch. Thus the body is supplied by purely arterial blood and the heart is four-chambered. This implied an invigoration of life. It may be recalled that there is a four-chambered heart in *Crocodylia*, which have however a dorsal aorta made of two aortic arches and thus a supply of mixed blood to the greater part of the body. It was doubtless gradually that thermotaxis evolved; it implied the specialization of a heat-regulating centre in the brain, apparently in the corpus striatum, which reacts to slight changes in the temperature of the blood, and adjusts in relation to these the body's production and loss of heat.

As contrasted with the wings of insects, *Pterodactyls* and bats, those of birds are feather-wings and the acquisition of feathers was one of the main steps in avian evolution. But feathers may be correlated with the highly developed vascular system and the abundance of blood-vessels in the bird's dermis. While feathers are in a general way homologous with reptilian scales, they are quite unique integumentary structures, and no intermediate structures are known (see FEATHER).

Adaptations Effecting Improvement in Flight.—When flight had begun, adaptations effecting its improvement would

follow. Thus the skeleton would become more lightly built, the sternum would acquire a keel for the insertion of the muscles of flight, the neck would become long and supple, and the beak would take on the work of a hand. The flying movements would assist in the expiration of air from the lungs, so different from the active inspiration in mammals; and the need for keeping the total size of the bird relatively small may be correlated with the large internal surface of the lungs. It is useful to think of accessory adaptations being added to the essential features, which may be associated primarily with the high intensity of metabolism.

One of the marked differences between birds and reptiles is the great increase in the relative size of the brain. This may be associated with the very perfect locomotion, which is in part co-ordinated by the cerebellum, and with the fine manipulations involved in nest-building, which have their centres in the cerebral hemispheres. Most birds are small and delicate, with little in the way of armour or weapons, and they are therefore more dependent than reptiles on brains and wits. The high development of the senses of sight and hearing, essential to life-saving alertness, is also to be correlated with increased size of brain.

The flying habit made it possible for birds to deposit their eggs in safe places; economized reproductivity became practicable; and with this there must have been correlated variations in the direction of increased parental care. The comparative safety secured for the eggs and young allowed a long period of development before hatching, a possible prolongation of sheltered infancy in the nest, and the further possibility of lengthening out the nurture period in which the capacities of the young creatures are educated and their new departures tested. All this would favour the improvement of the brain and its associated mentality.

It is plainly advantageous that flying creatures should have a sharply punctuated reproductive period, and that the gonads should not be large throughout the year. This punctuation of the reproductive period probably means an intensification of the emotions in courtship and in family life, and may be correlated with the high tide of feeling expressed in song. This points the way to increased utilization and possible socialization of the voice, so familiar in rooks. In this respect birds stand out from reptiles as men from apes, with parallel brain-increase in the two cases.

The object of this introduction is to suggest that many of the salient features of birds are congruent or correlated, and also to indicate the deep constitutional characteristics which may be reasonably regarded as the pre-conditions of flight. These deep characters are intensity of metabolism, spare muscular habit of body, rapid bipedal progression, the supply of the body with arterial blood exclusively, and that of fine quality, the perfect warm-bloodedness except in early youth, the assisting of respiration by locomotion, and a well-developed brain. Given these features, it is easier to understand how the evolution of feathers would make flight possible. Then would follow a score of accessory adaptations to this mode of locomotion.

FLIGHT OF BIRDS

The problem of flight has been solved (1) by insects, in which the rapidly vibrating wings are flattened outgrowths of the dorso-lateral body-wall of the meso- and meta-thorax, worked by strong muscles at their base; (2) by the extinct Pterodactyls, in which a fold of skin was extended on the greatly elongated outermost or fifth finger; (3) by birds, in which the transformed fore-limb owes its striking surface mainly to the feathers; and (4) by bats, in which a fold of skin, beginning at the neck, is continued along the anterior surface of the arm, then between the greatly elongated fingers and palm-bones, and onwards along the sides of the body to the hind-legs, and to the tail if that is developed. The four solutions are obviously quite different.

It is probable that birds were given to swift running before they were able to fly, and that the beginnings of flight were long flying leaps. It is likely that they practised parachuting from tree to tree, as some reptiles, like *Draco volans*, still do, before there was true flight. It is likely that there was a prolonged arboreal apprenticeship, which is pointed to, for instance, by the gripping arrangements of the toes of birds, and also by the

active climbing of the young of the primitive hoatzin (*Opisthocomus*) which uses its clawed hands as well as its feet in moving from branch to branch.

Mechanism of Flight.—In ordinary flight the wings combine the functions of propellers and planes. From a raised position sometimes vertically above the back, they are pulled forwards downwards and backwards by the contraction of the large pectoral muscle, and then raised again by the pectoralis minor whose tendon works through a pulley at the shoulder-joint. The tip of the wing describes a curve somewhat like an asymmetrical figure eight. The downward component of the wing-stroke, displacing a mass of air, keeps the bird up or raises it; the backward component gives it horizontal velocity; but the resistance of the air, which tends to retard the forward movement, has an important lifting function, for it works upwards against the ventral surface of the body and the slightly concave under-surface of the wings. Between successive strokes there is bound to be some loss of altitude and momentum, but this is almost inappreciable. It is lessened by economizing energy in raising the wing. This is effected by an automatic reduction in the size of the wing when it is not pressing down against the air, by a movement of the individual feathers so that air passes between them, and by the convex upper-surface which allows the air to glide off easily. For physical reasons an increase in the rapidity of flight up to a certain limit lessens the proportion of energy required; it is relatively more economical to fly quickly. Marey calculated that the energy expended by a pigeon when first taking flight is five times as great as when it has acquired its average. Among the most important adaptations to flight are—the shape of the body and the external reduction of frictional resistance; the light build of the skeleton which affords large surface for the insertion of muscles and feathers without great increase of weight; the insertion of the wings high up on the thorax and the ballasting of the body with the heavier organs, such as liver and gizzard, below, so that the centre of gravity is far below the centre of suspension; the strong development of the pectoral muscles and of the keel on which they are ventrally inserted; the possibility of increasing "sail-area," by lengthening the feathers, without involving much corresponding increase in weight or size of skeleton.

The secondary feathers, attached to the ulna, are of major importance in the wing-stroke; the longer primary feathers, attached to the hand, are of great use in lateral steering, hence their prominence in the insect-catching swallows and swifts. Steering is effected mainly by the differential action of the wings, but also by altering the tilt and pose of the body and by moving the tail-feathers, which likewise serve for balancing and as a brake. A quickly flying insect like a bee may have 200–300 strokes per second; in its ordinary flight a sparrow has per second 13 strokes, a wild duck nine, a carrion-crow three–four, a stork two, and a pelican one and one-sixth.

Gliding.—Besides ordinary flight, there is gliding, when the bird having attained to a certain velocity rests on its oars for a while; or having attained a certain height descends to the ground without any stroke of its wings. It is probably the most primitive mode of aerial locomotion, parachuting rather than flying. A gull or a heron or any bird with a large sail area, having attained a certain velocity, planes with motionless wings, "like an aeroplane with its engines shut off," getting the necessary "lift" from the air-resistance to its forward movement; but this cannot continue long without loss of position, unless there is a strong up-current of air, as from the face of a sea-cliff. Guidance during gliding may be effected by movements of the tail, head and neck, and by tilting the outstretched wings. It would be convenient to use the term "gliding" for everyday exhibitions such as gulls illustrate. Then the term "sailing" might be conveniently retained for extraordinary exhibitions such as the circling of the albatross around a ship. The peculiarity in this case is that the bird sails with and against the wind without visible wing-strokes for perhaps half an hour at a time. It takes advantage of currents of air of unequal velocity at different heights. It glides down the wind, with increasing velocity but sinking a little; it wheels and rises into a less rapid current, with reduced flight velocity, changing part of

its energy of motion into energy of position. The term "spiral sailing" might be restricted to cases like vultures and storks when they rise without up-strokes in slow spirals to a great height. It implies a steady, strong up-current of air, and is most frequently seen in warm countries. It seems undesirable to continue to call this soaring, a term indissolubly associated with the lark climbing the sky. In this case there are very rapid wing-strokes, with the downward component predominating. The soaring of the lark comes close to the hovering of the kestrel or humming-bird, in which the rapid wing beat is devoted to keeping up the bird.

Velocity of Flight.—In thinking of the velocity of flight it is obviously necessary to distinguish between "air-speed" and "ground-speed." A bird that seems to the observer to be stationary may be flying hard against the wind. "A bird flying at 30m. per hour in a 20m. wind will seem from the ground to be making either 50m. or 10m. per hour according to whether it flies with or against the wind." The most accurate measurements are those made from aeroplanes on birds keeping level with the machine and flying in the same direction. Thus measured by Meinertzhagen, small song-birds show an average rate of 20-37m. per hour, crows 31-45, ducks 44-59, plovers 40-51; but these may be increased in exceptional circumstances, and an occasional rate of 100m. an hour is quite credible. "Swifts of our common species, feeding 6,000ft. above Mosul, were noted as easily passing and recircling about an aeroplane which was registering 68m. an hour."

The value of flight is obvious, but it may be useful to recall some of the different ways in which it has justified itself in the struggle for existence. It gave its possessors a new safety and independence; it enabled them to follow food and to seek water over long distances; it helped them to secure the well-being of their offspring by building nests in places often inaccessible except to enemies able to fly or climb. The power of flight in its high development also gave birds a unique power of annihilating distance, of evading the winter, of having two summers in the year, of having two homes, of changing their season in a night. In seeking out suitable feeding-places and breeding-places neither space nor time present obstacles to the flying bird.

FEATHERS AND PLUMAGE

While there is no known connecting link between a feather (*q v*) and an epidermic scale, the development of the two structures is not very different. Both arise from expanded papillae of the epidermis, with the cells transformed into horn; and both are fed, as long as they grow, by pulp-like upgrowths of the under-skin or dermis, containing minute blood-vessels. There can be no hesitation in comparing the scales on a bird's toes and in-step-region, as also on the bill, with the typical scales of reptiles; but it should be noted that what is moulted in reptiles is the outermost dead layer of the epidermis covering the scales, whereas in birds the whole feather is thrown off. Feathers are unique structures whose evolution is obscure.

The Parts of the Feather.—An ordinary feather shows the following parts: (1) the cylindrical hollow barrel or calamus, whose base is embedded in a follicle of the skin; (2) the main shaft or rachis, filled with white pith, and somewhat quadrangular in cross-section, but convex externally and concave internally; (3) the vane, consisting of a bilateral web, which in the case of the pinions serves to strike the air, and is built up of biserial barbs united by barbules and microscopic barbicels; and (4), it may be, an aftershaft or hyporachis, which arises to the inner side at a little pit marking the junction of calamus and rachis, and usually consists of a tuft of barbs, often with barbules. In a few cases, such as the cassowary, the aftershaft is as long as the shaft, and the feather looks as if it were double. The most important structural fact is the webbing of the vane, so that it forms in the pinions an efficient instrument for striking the air. In feathers not used in flight the coherence of the parts of the vane helps to keep air imprisoned below, to lessen the loss of heat and to protect the skin from being wetted. A bird's feathers occasionally occur all over the skin (in penguins), but they are usually disposed in regular rows (feather-tracts or pterylae), which show particular patterns in different types.

Preen-gland.—Apart from the occasional presence of glands near the ear opening, the bird's skin has only the preen-gland; and even that may be absent, as in ostrich, bustard, and some parrots. It is best developed in aquatic birds, and this is particularly associated with the need for water-proofing the plumage. Some mammals lick and brush their skin, but in the main the fur is kept in good order automatically. Birds, on the other hand, attend to the feathers individually, and they may be sometimes seen reaching back with their bill to the preen-gland, which produces an oily secretion. But some birds, like the scissor-bill (*Rhynchops*) and the pelican could not readily compress their preen-gland, and in many cases the secretion is very small in amount compared with the extent of the plumage. Moreover, some birds without a preen-gland keep their feathers in good order. It has been suggested by W. P. Pycraft that the preen-gland may be a scent-gland, helping in the recognition of kin. But most birds have a poorly developed sense of smell. It is possible that a drop or two of the oil stimulates the secretion of the salivary juice, which helps in preening. According to Paris the removal of the preen-gland makes no difference to the bird. The structure of this organ resembles that of the odoriferous glands of some reptiles; it is a bi-lobed subcutaneous mass of glandular tubes, supplied by blood-vessels and nerves, surrounded by a capsule of connective-tissue, but without muscle-fibres except at the opening.

Moult.—After a feather is fully formed the component cells begin to die away, and the pulp retreats into the skin, leaving little partitions or "caps" across the interior of the calamus. It follows that there can be no repair of worn feathers, and it is therefore advantageous that there should be "moult." Moult usually occurs after the fatigue of the breeding season and before the autumnal migration, but in some birds, e.g., swallows and hawks, it occurs in mid-winter. The process of shedding the old feathers and replacing them is usually spread over a considerable time, but it may be so rapid that the bird is left very naked. Moulted geese, ducks and rails lose all their pinions at once, and are for a time unable to fly.

All birds moult once a year; but some moult twice. There is often a special spring moult, when the males put on their nuptial plumage. The ptarmigan has three moults in the year. There are many other exceptional features; thus the penguins moult their feathers in patches, not individually. The physiology of moulting is very slightly known, but there is much interest in Beebe's experiments (1914) on the males of the scarlet tanager and the bobolink, in which a brilliant summer plumage normally alternates with a totally different winter garb. At midsummer the birds were placed in small cages in a quiet room, with gradually diminishing light and slightly increased food. The birds ceased to sing, put on fat and increased in weight. Thus the modified environment brought about a bodily condition very different from the thinness and fatigue that normally follow the strain and the cares of the breeding season. The autumnal moulting time passed without a single feather being shed. Early in spring some of them were gradually brought into normal conditions, whereupon the spring moult took place, the birds passing directly from one nuptial plumage to another. Beebe's conclusion was that the condition of the birds as regards fatness or thinness determines whether they shall moult or not. Side experiments showed that the seasonal "pigmental changes in the blood" go on as usual, for one of the tanagers, subjected to rapidly altered temperature, underwent a belated moult into the green winter plumage. Thus it is plain that the succession of plumages is not rigidly predetermined; there is a plastic correlation of internal constitutional rhythms and external seasonal periodicities.

Feathers often illustrate an unsurpassed combination of pigimentary and structural coloration (see COLOUR OF ANIMALS).

Chief Uses of Feathers.—In connection with the variety of plumage, it is useful to bring together the chief uses of feathers, which must have been subjected to selection with reference to many different advantages: (1) the primary use was probably to form a relatively non-conducting robe which tends to retain the animal heat. This may be aided by layers of air included between

and below the feathers; (2) the plumage may also save the skin from being wetted. This prevention of wetting varies in different birds, (3) the feathers made flight possible, and here may be noted the light elastic build, the resistance to wear and tear, the almost air-tight linkage seen in the vanes of the pinions, and the possibility of attaining great length without much weight; (4) the plumage often renders the bird inconspicuous in its habitual surroundings. Thus the brooding woodcock among the fallen leaves and withered herbage has a very effective cloak of invisibility. Very common is the obliterative counter-shading seen in a bird like a curlew or a sandpiper, whose plumage is lighter below and slightly darker above, the two shades blending on the sides. Another type is seen in the irregular or dazzle pattern, where variety in different parts breaks up the shape of the body, a good example being the golden plover. This type of protective coloration has the advantage of being effective against diverse backgrounds; (5) conveniently separable, perhaps, from protective coloration is that which masks aggressive birds in the eyes of their victims, as may be the case with the Greenland falcon and the snowy owl. Here might be included other qualities of the plumage useful in the chase, such as the softness that makes the flight of owls so noiseless; (6) when there is a profitable resemblance to other birds, the term "mimicry" may be legitimately used. A weak species may profit by being like a strong one, a predatory bird by being like a peaceful one. A. R. Wallace pointed out that the friar-birds of the Malay Archipelago, large, strong, gregarious, assertive honey-eaters, holding their own against birds-of-prey, are "mimicked" by the weaker orioles, and that the particular species of friar-bird on each island has its corresponding mimetic oriole! "Of aggressive mimicry, a good example is the caracara of South America, a carrion-eating hawk which also catches small birds by stealth. It is enabled to do so by its close superficial resemblance to a species of curassow, a harmless game-bird, which is common in the same region"; (7) feathers are often auxiliary to the appeals made in courtship. They may enhance the brilliance of the male bird; they may be exaggerated into extraordinary decorations, as in birds of paradise; they may form tufts and crests erectile in excitement; they may be used to produce arresting sounds, as in the "drumming" snipe; (8) in many cases, reaching a climax in eider-duck, feathers are used in nest-making, conserving the heat around the nestlings, and making brooding more comfortable; (9) finally, there are various minor uses, such as helping in recognition of kin by kin.

SKELETAL ADAPTATIONS

The bird's skeleton affords numerous instances of adaptations, as might be expected since there are in most cases two different kinds of locomotion, flying and running, and sometimes swimming as well. The term "adaptation" is here used to express not a process but a result, a particular adjustment of structure well suited to discharge certain functions.

Lightness of Skeleton.—The lightly built skeleton is adapted for flight. This implies that the medullary cavities of the long bones are large, that they are often without marrow in adult life, that many contain air-sacs continuous with the lungs, and that they frequently show spongy bony tissue below the hard and compact cortex. Thus the skeleton is built on the hollow girder principle, with a relatively large surface for the insertion of muscles, yet without the corresponding increase of weight that would be involved if the bones were as substantial as those of reptiles and mammals. Long bones with large cavities also occur in bats and in Pterodactyls. In some birds, such as the albatross, practically every bone is "pneumatic" except the scapula and the hyoid.

The Fusion of Bones.—A second general character of the bird's skeleton is the tendency of adjacent bones to fuse together while still in the making. This occurs in many parts of the body. Thus, except in running birds, most of the bones of the skull coalesce early, which may be in some cases adaptive when the skull as a whole is used as an instrument; e.g., as a hammer in woodpeckers, or for tearing up a victim in birds of prey. The fusion of most of the thoracic vertebrae in ordinary flying birds affords a firm fulcrum for the down-stroke of the wings. This

interpretation is confirmed by the absence of fusion in running birds and by the tendency to coalescence in the thoracic vertebrae of bats. The fusion of several vertebrae (thoracic, lumbar and caudal) with the true sacra, to form a syn-sacrum, and the fusion of this with the entire length of the iliac portion of the pelvic girdle, must be interpreted in adaptation to bipedal progression. So much of the bird's body is usually in front of a perpendicular dropped from the acetabulum, with which the head of the femur articulates, that it is necessary for balancing purposes that the hip-girdle should take a long and strong grip of the backbone. The point is emphasized if the bird's hip-girdle be contrasted with that of the jumping and swimming frog, which cannot stand on its hind legs, and has only a single sacral vertebra with which the thigh-bone has merely a ligamentary attachment. In all modern flying birds (Carnitae), though not in running birds (Ratitae), there is a fusion of about four terminal vertebrae to form the ploughshare bone or pygostyle. This is in great contrast to the long lizard-like tail of the earliest known fossil bird (Archaeopteryx), which had 20 free vertebrae. In ordinary flying birds the ploughshare bone forms a basis for the insertion of the tail-feathers or rectrices, and may thus be interpreted as adaptive. Reference will be made later to the fusions that occur in the regions of the wrist and palm and in the region of the ankle and instep. In the running birds, where the pectoral girdle is unimportant, the scapula and the coracoid are fused into one bone.

Other Adaptations to Flight.—Some additional adaptations to flight may be summed up. The keel or carina on the sternum serves for the insertion of the pectoral muscles, and its varying prominence in relation to the body of the sternum in different types stands in correlation with the power of flight. A keel is slightly developed in bats and also in moles, both of which have strong pectoral muscles. It is absent in Ratitae. It is degenerate in the rare burrowing parrot (*Stringops*) of New Zealand. In contrasting the Carinate and the Ratite breast-bone, it is interesting to notice that the former is usually carried far back, forming a supporting floor for the viscera, of especial value in flying and swimming, whereas the latter is a broad shield, not carried backwards, the weight of the viscera being borne by the thoracic and lumbar vertebrae, and by backward extension of the rib.

The sabre-like scapula of flying birds is bound by ligaments to the ribs and backbone; the strong coracoid is braced movably in a deep groove on each side of the front of the breastbone; the clavicle extends crosswise in front of the heart, and has its middle piece attached by ligament or sometimes fused to the tip of the keel; except in the South American screamers (Palamedeae) many of the ribs have a backward-projecting uncinate process, which overlaps the rib behind, to which it is lashed by ligament, thus binding the rib-system into a coherent basket; the lower or sternal parts of the ribs, which reach the breastbone, are bony, not gristly as in mammals. The total result is to form a coherent springy framework (of backbone, breastbone, ribs and pectoral girdle) against which the wings can work with maximum efficiency. The arrangements prevent any incrusting on the heart during the down-stroke of the wings, yet the alteration in the capacity of the chest cavity, as the breastbone is raised and the backbone depressed, facilitates the outrush of air from the lungs. The glenoid cavity, formed by the junction of scapula and coracoid, is much more open than in mammals, and is thus well suited for the free play of the wings. If the clavicles, forming the merrythought, are broken, the bird cannot fly. They are rudimentary or absent in running birds, and reduced in some birds that do not fly much; e.g., certain parrots. Hilzheimer calls attention to the marked mobility of the joint between coracoids and sternum in humming birds, and connects it with the great rapidity of the wing-strokes. It allows rapid expansion and compression of the chest-cavity, thus facilitating respiration. In general, it is one of the perfections of birds that flying helps breathing.

In the wing itself the chief adaptation is that there is greatly reduced mobility in the different parts, so that the feather-bearing skeleton works as a unified whole. Thus in flight the radius does not move on the ulna; there are only two free wrist-bones; the distal half of the wrist and the whole of the palm-bones—six

bones in all—are fused to form the carpo-metacarpus, carrying most of the primary pinions; the thumb has considerable mobility, but the two other digits are stiff. But while the fore-limb may be said to act *en bloc* in striking the air, the other side of the adaptation is the way in which it folds up in one plane into the resting position, forming a compressed letter Z, the elbow pointing backwards, the wrist joint forwards, the tips of the digits (probably I., II., and III.) backwards. This is a space-economizing arrangement, useful when the bird is swimming or diving with its feet, or threading its way afoot through thick herbage.

Adaptations to Bipedal Progression.—Among the adaptations to bipedal progression, we have already noticed the synsacrum, which consists in a pigeon of one thoracic vertebra, five or six lumbar, two sacral and five caudal. This gives the hip-girdle a long and strong grip of the backbone, and thus facilitates balancing the body on the rounded head of the thigh-bone. The elongation of the different regions of the leg is suited for rapid running, and the most striking feature is the long, more or less vertical, tarso-metatarsus—a unique piece of skeleton. Except in the two-toed ostrich, it consists of three coalesced metatarsals (or instep bones), and to the upper end of these the distal ankle-bones or tarsals are fused. With the exception named, the lower end bears three articular knobs, for the three toes. If there are four toes, the first is turned backwards, and has a small separate metatarsal of its own. The tarso-metatarsus adds to the bird's running power and swimming power, and in the divers and their relatives it is laterally compressed into a narrow blade, which reduces friction in preparing for a stroke and concentrates the force in the region of the foot when the backward stroke is made. At the bird's ankle-joint, two rows of small tarsal bones would naturally be looked for, and they are indicated in the embryo. But just as the distal row fuses to the fused metatarsus, forming the tarso-metatarsus—six bones in all—so the upper row fuses to the lower end of the tibia, forming the tibio-tarsus. Thus all the ankle bones have disappeared as such, and this, considered in relation to the elongated tarso-metatarsus, may be of mechanical advantage when the bird springs from the ground or rapidly alights.

The skeletal adaptations of the toes are illustrated in a special plate, and it will be enough to mention the powerful talons of birds-of-prey for gripping and carrying the booty; the elongated toes of the jacana, for walking on floating leaves; the unusual arrangement in the cuckoo, the first and fourth toes pointing backwards (with the fourth reversible), the second and third forwards, for firm perching; the same appearance in trogons, but with the first and second toes backwards, and the third and fourth forwards; the forward directed four toes of the swift, for climbing or for clinging to the nest. In divers and grebes and the extinct *Hesperornis*, there is an interesting prolongation of bone rising from the head of the tibia above the knee-joint. As a basis for strong muscles it gives much additional power to the swimming stroke.

Other Adaptations.—The surrender of the fore-limb to wing-making implies an assumption of new functions by the skull, which becomes a manifold instrument. Perhaps this is facilitated by the early fusion of most of the cranial bones in flying birds, and it is interesting to notice that similar fusion occurred in the Pterodactyls. The exaggeration of the premaxillae to form a beak is an obvious adaptation. Detailed adaptations of the bill are shown in a special plate. The lower jaw consists of six bones on each side, a point that reveals the affiliation of birds to reptiles. More important, however, from our present point of view, is the loose articulation of the lower jaw with the movable quadrate, for this increases the gape—an important feature. Thus it facilitates the rapid swallowing of large booty, and catching small insects in mid-air. The delicate nature of the infra-temporal bar may be correlated with the usual absence of mastication; and where teeth are absent it is not surprising to find the maxillae are small.

The importance of vision in birds is correlated with the large orbits, and these with the restriction of the cranial cavity to the posterior region of the skull, which is markedly broadened.

One of the most striking advances of birds, as compared with reptiles, is in the proportion between the brain-containing region and the size of the skull as a whole. The skull has great mobility on its single occipital condyle (another reptilian feature); and here should be noted the mobility of the neck with its characteristic heterocoelous vertebrae. The bill can reach the preen-gland; the head may be seen resting between the shoulder-blades with its point towards the tail.

FOOD

In birds, as in all other animals, both structure and habits are in great part concerned with the quest for food: (1) many birds are vegetarian, eating fruits, seeds, buds, leaves. Most humming birds and honey-eaters suck up nectar; geese graze on grass; grouse devour heather tips; ptarmigan often feed on the mountain lichens; (2) many birds are carnivorous, eating small mammals, other birds, reptiles and amphibians, fishes, slugs, insects and lower animals like earthworms. Kestrels destroy voles, the golden eagle sifts the grouse, the secretary bird kills snakes, storks swallow frogs, the flying osprey catches the swimming fish in its talons, rooks let freshwater mussels fall from a height on the river gravel, the thrush breaks the shells of snails on its anvil, the cuckoo is partial to hairy caterpillars, the swallow catches small insects in mid-air, the woodcock depends mainly on earthworms. The most important ecological fact is the indispensable check that birds keep on the multiplication of insects which would otherwise ruin the world; (3) many birds enjoy both vegetarian and carnivorous diet. Thus the thrush likes fruit as well as slugs; the normally fish-eating herring gull has become a devourer of turnips, potatoes and grain. Of special interest among the mixed feeders are those which give their young ones material different from that which forms the staple food in adult life. Thus young rooks, sparrows and finches are fed for a time on insects only. In many cases the diet has necessarily to vary with the seasons; (4) there are many strange oddities of diet. Thus the kea parrot (*Nestor notabilis*) of New Zealand has learned to settle down on a disabled or dead sheep and dig out the fat and flesh from near the kidneys. This is a strange idiosyncrasy on the part of a bird that belongs to a race habitually vegetarian or frugivorous; and it must have arisen rapidly, for sheep were not taken to New Zealand till about 100 years ago. The red-winged starlings of South Africa include in their menu the berries of the syringa, which they eat in such quantities that they become stupefied by some included narcotic. Similar intoxication has been observed in birds that devour fermenting fruit. Another quaint misadjustment is seen in some sea-birds, like the albatross, which may make such a hearty meal that they cannot rise off the water.

Methods of Obtaining Food.—It is ecologically interesting to select a particular kind of food, let us say, fish, and to notice the variety of ways in which it is obtained. The hovering osprey catches the fish in its talons, the swooping herring-gull with its bill, the gannet dives from a height, the cormorant turns head over heels from the surface, the scissor-bill skims the waves, the heron usually waits for a fish to swim past, the kingfisher makes a sudden plunge, the pelicans sometimes wade shorewards in a crescent, penguins pursue their booty under water, the skuas chivy the herring gulls in the air and force them to disgorge. In the ways in which food is detected, acuteness of vision counts for most; a tactile bill is important in probing birds like snipe and woodcock; of smell there is not much evidence.

Another line of enquiry may be illustrated by the way in which the bills and feet of birds are suited to particular kinds of food and food-capture. The absence of teeth in modern birds is compensated for by the horny bill covering the jaws. It often has a sharp edge and a hooked tip; it varies from a massive crushing instrument in the toucan to a delicate probe in the humming bird. The variety of type should be considered in the light of the fact that the fore-limb has been surrendered to making a wing, and that the bird's jaws have to discharge duties which in mammals usually fall to the hands.

"Bill" and "Beak."—The bones covered by the horny bill are especially the premaxillae above and the complex lower jaw

(d) there are numerous small pebbles which help to triturate the food. As these grind-stones get their corners rubbed off, they slip down the intestine. There are many strange gizzards, such as that of some fruit-pigeons, which has numerous hard conical projections on the internal lining, or that of the snake-bird (*Anhinga*), which shows a sieve of hair-like processes at the duodenal end. These prevent unbroken fish-bones and the like from passing into the intestine. When the male hornbill (*Hydrocorax hydrocorax*) passes food to his imprisoned mate, the packet is often surrounded in a tough homogeneous skin which arises as a secretion of the walls of the gizzard.

The Rectum.—The most marked anatomical peculiarity of the rest of the alimentary canal in the bird is the shortness of the rectum, which is often not more than an inch long. This shows that there must be great efficiency of digestion in the much looped small intestine. The amount of faecal matter is relatively small. At the junction of the small intestine and the rectum there are usually two caeca, which occur in all sizes from mere vestiges, as in the pigeon, to long functional tubes, as in the duck. When well developed they serve to delay the food and facilitate absorption. The terminal chamber or cloaca receives the ureters and genital ducts, and bears a dorsal pouch, the bursa Fabricii, which functions in young birds for the formation of white blood corpuscles.

Respiration.—Some of the important peculiarities are the following: the bird's lungs, though small and hardly distensible, have through the complex branching of the bronchi, a very large internal surface for gaseous interchange; the driving out of the air from the lungs, which are fixed to the ribs, is assisted by the strokes of the wings, expiration is the active part of the respiratory process, not inspiration as in mammals; the lungs open into a system of transparent, internally ciliated air-sacs which economize the work of breathing and increase the total content of air; this is useful in prolonged diving and in enthusiastic song; they allow of a "double tide" in every respiratory act, thus in expiration air passes out from the lungs to the exterior, but also into the lungs from the air-sacs; they promote internal perspiration, for water-vapour passes into them from the blood, thus helping to regulate the temperature of the body.

The Glottis.—At the back of the tongue lies the glottis or opening of the windpipe, with never more than a hint of the epiglottis characteristic of mammals. The glottis leads into the larynx, supported, as in amphibians, reptiles and mammals, by transformations of the representatives of the branchial arches of fishes. But the larynx of birds contains no vocal cords, these being situated at the lower end of the windpipe (trachea) in the enlargement known as the syrinx. This varies considerably in development and is absent in ostriches, storks and some vultures. The voice is due to the rapid passage of out-breathed air over the vibrating vocal cords. The trachea is supported by bony rings. It is interesting to notice that the syrinx arises as a transformation of the base of the trachea and of the beginning of the two bronchial tubes. In contrast, again, with mammals, there is no true diaphragm, shutting off the chest from the visceral cavity.

The Heart.—The bird has a four-chambered heart, with a complete separation of arterial and venous blood, as in mammals; but the aortic arch, carrying pure blood to the body, turns to the right in birds, to the left in mammals. The blood of birds has more red blood corpuscles per ounce than that of any other animal, and this is an adaptation to intensity of metabolism and to aerial habits. The red blood corpuscles are elliptical, slightly bi-convex, nucleated discs, like those of lower vertebrates, but unlike those of mammals, which are non-nucleated, slightly biconcave and generally circular in outline. On the whole the red blood corpuscles of birds are large as compared with those of mammals while the diameters in man, dog, horse and ox are $7.5\ \mu$, $7\ \mu$, $6.5\ \mu$, and $5.5\ \mu$, in the high-flying vulture $17.7\ \mu$ by $8\ \mu$ (μ is $\frac{1}{1000}$ of a millimetre, about $\frac{1}{25000}$ in.). There are several kinds of white blood corpuscles or leucocytes. Of special interest are the phagocytes, mobile amoeboid cells, able to leave the blood altogether and to migrate into the tissues, where they engulf microbes, devour degenerating tissue, transport material from one area to another, and help to repair injuries.

As might be expected in animals of predominant muscularity and intense metabolism, the temperature of the bird's body is high, from 2° – 14° higher than that of mammals. Regulation of the temperature is automatically effected by a thermotaxic nerve-centre in the corpus striatum of the cerebral hemispheres. If the temperature of the blood changes, the centre, being stimulated by the blood-stream, sends nervous impulses to the muscles, the skin and other parts, regulating the production and loss of heat. These arrangements have not been completed in nestlings, which are therefore apt to suffer from over-heating or over-cooling.

Excretion.—In organisms so active as birds there is necessarily a large production of nitrogenous waste-products, due partly to the wear and tear of the protein framework of the cells, and partly to the nitrogenous residue of the amino-acids into which the food-proteins are changed by digestion. The elimination of the poisonous nitrogenous waste is prepared for in the liver, and completed in the tri-lobed kidneys which lie below the hip girdle. The result of the filtration is a clear fluid which passes from the kidneys by the ureters to the cloaca; but there, by losing water, it turns into a semi-solid mass of urates. This nitrogenous waste forms the guano of bird-islands, such as those of Peru.

The Endocrinal Glands.—It is impossible to understand the bird's bodily life without taking account of the regulatory system of endocrinal or ductless glands—such as the paired thyroids near the base of the neck, the yellowish supra-renals lying on the front part of the kidneys, the pituitary body on the under-surface of the brain, and the glandular tissue in the reproductive organs. These structures produce hormones which are distributed through the body by the blood, and help to secure a harmonious regulation of function. Those produced by the endocrinal tissue in the gonads are important in activating or in inhibiting such structures as decorative plumes and such activities as song.

BEHAVIOUR

Sight.—The bird's sense of sight is highly developed, and the power of rapid accommodation surpasses that of all other vertebrates. The rods of the retina, which have to do with discrimination of form, far outnumber the cones, which are believed to have chiefly to do with colour-sensation. Experiments show that birds cannot see blue or violet, but they distinguish colours towards the other end of the spectrum. The usual six muscles of the eye are reduced in size, and the spherical shape of the eyeball, adapted to ready mobility, is usually departed from, though approached in ostrich and vulture. It is likely that the reduced mobility of the eye is compensated for by the freedom of movement of the neck. The eyes are markedly to the sides of the head, commanding two visual fields. The vision is strictly monocular.

Hearing.—The sense of hearing is acute, but it has been observed that many kinds of birds are indifferent to even loud noises. Attention is most readily given to sounds which stimulate or interest either an inborn equipment or an acquired association. The parental danger note stimulates the crouching instinct of the young partridge; a bird will sometimes answer back to an artificial kin-call. The semicircular canals of the ear show some correlation with the perfection of flight; thus they are better developed in a swallow than in a swimming bird. Birds resemble reptiles in having no ear-trumpet or pinna, such as is seen in most mammals. Its absence in birds may be correlated with the mobility of the head and with the advantage of reducing friction; but the close affinities of birds and reptiles must be kept in mind.

Smell.—The sense of smell has been strictly demonstrated in night-hawks, owls, magpies and some other birds, but not in many. It is by sight, not by smell, that the vultures gather to the carcass. A few birds have themselves strong odours, but recognition of kin is mainly by sight. According to some naturalists, the odour of a bird—e.g., a partridge—is reduced to a minimum when brooding. As to tactility, there is not very much, for there is little exposed skin; but there are nerve-endings at the base of some of the feathers; the tip of the tongue, as in ducks, may serve as a touch-organ; and there may be a strong development of tactile nerve-endings in the white cere near the nostrils, or at the tip of the probing bill, as in woodcock. Taste papillae

have been demonstrated on the tongue of a few birds, but this sense is usually slight. Little is known of the other sensory "receptors," such as those responsive to temperature and pressure.

Brain.—The brain, compared with that of reptiles, fills a relatively large cranial cavity, and both the cerebrum and the cerebellum are large, the former covering the region of the optic thalami and the latter hiding the medulla oblongata. The optic lobes, which are on each side of the middle line in the young embryo, are displaced to the sides by the disproportionate growth of cerebrum and cerebellum. It may be that the large size of the cerebellum, which is transversely grooved, has to do with the bird's locomotor achievements, for this part of the brain has in part to do with the control of movements. The cerebrum, the seat of the higher mental functions, differs from a typical mammal's in being without convolutions and in having no more than a trace of the important transverse commissure, the corpus callosum. The roof of the cerebrum is relatively thin and the main mass consists of corpora striata.

Reflex Action.—When a nestling opens its mouth at the touch of food in its mother's bill, that is a reflex action. It is dependent on pre-arranged linkages between certain nerve-cells—(1) sensory, (2) associative, and (3) motor—and (4) certain muscle-cells. The linkage is part of the characteristic hereditary organization; no learning is required for a reflex action; the higher nerve-centres are not concerned. There are many of these reflex actions in birds, as in other higher animals; and sometimes they are complex or serial, one leading on to another. Thus the nestling's opening of its mouth is followed by other reflexes of gripping and swallowing the food. It is probable that the movements made by a young bird just before hatching are mainly reflex. Inborn reflexes, dependent on pre-established neuro-muscular linkages, must be distinguished from individually acquired associations, as when a bird acts in a particular way in response to a particular sound or sight. This may become automatic.

Instinctive Behaviour.—When the activity evoked by a stimulus is a chain of acts on the part of the creature as a whole, following a definite routine and requiring no apprenticeship, it is called instinctive behaviour. From the physiological side, instinctive behaviour is like a chain of compound reflex actions, each pulling the trigger of its successor; but to many naturalists it seems necessary to postulate a psychical side also. In contrasting it with intelligent behaviour, emphasis should be laid on the fact that the routine performance as in swimming or diving when tumbled into the water, does not require apprenticeship, and may be exhibited in perfection the first time. Moreover, it is limited by the apparent absence of any understanding of the situation.

Instinctive behaviour is not all at the same level, for there is a gradation from short and simple activities, as in pecking, scratching, swimming, diving, flying, crouching and lying low, to long and complicated chains as in nest-building. Care is necessary to discriminate inborn capacities from the results of early education on the mother's part. This may be done by hatching the young birds in an incubator. Thus Prof. Lloyd Morgan found that his chicks, incubated in the laboratory, paid no attention to their mother's cluck when she was brought outside the door. Although thirsty, and willing to drink from a moistened finger-tip, they did not instinctively recognize water even when they walked through a saucerful. Only when they happened to peck their toes when standing in water did they appreciate water as what was needed to relieve a state of dissatisfaction. But then, the bill being moistened, they drank eagerly, lifting the bill to the sky in the instinctively prescribed fashion. In natural conditions the mother-bird may play an important part in supplying stimuli which liberate instinctive predispositions; thus the great crested grebe takes the young ones on her back and then sinks beneath the water, leaving them afloat.

Instinctive behaviour is often very precise and even specific, thus the cormorant's dive involves a complex series of movements, yet it has not to be laboriously learned by the young bird. But in the big-brained bird there is more freedom than in the small-brained bee, and this is seen (a) in the control of instinctive capacities in response to parental training, (b) in a "trial and

error method" of using the instinctive reactions, in novel situations, and (c) in the modification of instinctive behaviour in the light of intelligence. Lloyd Morgan's chicks stuffed their crops with worms of red worsted, but they did not make this mistake more than a few times. The captive cormorants in the Amsterdam Zoological Gardens learned to associate a line of bubbles rising to the surface with the possible presence of fishes.

In training educable birds like the weaver-bird (*Ploceus baya*) advantage is taken of the capacity to form associations. Given a particular visual signal, the bird picks out a particular card. Given a particular auditory signal, a parrot will utter a particular collocation of sounds, with an appropriateness often misleading to those who know nothing of the training. Very remarkable is the homing of pigeons, but there is no doubt that a graduated apprenticeship educates an inborn aptitude. Very interesting and apart from definite training is the spontaneous establishment of useful associations, which may sometimes involve some awareness of the significance of the situation. A moorhen chick for which Lloyd Morgan used to dig worms, learned to run to him from a distance when he took the spade in hand. It need not be supposed that the bird had any intelligent appreciation of the spade as a digging instrument, the spade was simply an item in the mental registration of a pleasant experience. In natural conditions this type of association-forming must be common and invaluable.

Intelligent Behaviour.—As an instance of intelligent behaviour the following may be suggested. Herring gulls lift sea-urchins and clams in their bills and let them fall on the rocks below, thus breaking the shells. It is not necessary to credit the birds with thinking out the expedient, but it is difficult to evade the conclusion that what may have been discovered by chance, as often happens in mankind, is afterwards used intelligently.

The general impression left by a survey of bird-behaviour in such activities as nest-building and food-capture may be stated as follows. There is an instinctive basis, varying greatly in definiteness in different types; on this is built up a superstructure due to parental education, imitation, simple trial and error experimenting, and the establishment of simple associations; but above this there are instances of genuine intelligence, which cannot be described without crediting the bird with some appreciation of the relations of things, some power of perceptual (not conceptual) inference, in the light of which the behaviour is adjusted.

INTERRELATIONS

The circle of a bird's life intersects many other circles. Thus there are nutritive interrelations, such as the check that carnivorous birds, notably hawks and owls, impose on the multiplication of small mammals, other birds, some reptiles and amphibians, many fishes, molluscs, insects and worms. Similarly, there is the part that plant-eating birds play in destroying buds and young shoots, in digesting some seeds and scattering others. The list of "ornithophilous" flowers pollinated by humming-birds, honey-eaters, sun-birds, etc., is a long one. In estimating from the human point of view the gains and losses involved in the nutritive interrelations of birds, it is important to envisage the complexities of the case. A bird that does much damage in a fruit-growing country may be useful elsewhere. An estimate of the desirability of a bird from man's point of view should take account of its activities throughout the whole year, especially when it has two main kinds of food, such as seeds and insects. Taking a broad view, the great majority of birds do far more good than harm. (See ORNITHOLOGY, ECONOMIC.)

Food Supply and the Abundance of Birds.—The oscillations in the abundance of birds in connection with changes in the food-supply and in the number of enemies are of much interest. During a protracted plague of field-voles the number of short-eared owls has been observed to increase greatly; conversely, of course, the shooting down of owls and the like is apt to be followed by increase of field-voles. Destruction of rabbits may make foxes harder on pheasants; destruction of squirrels has been followed by great increase in the ranks of wood-pigeons, whose squabs are often eaten by the rodents. A great "lemming-year" in Greenland keeps the foxes well fed, and the ptarmigan

increase in numbers. But next year, when the lemmings are scarce and the foxes many, the ptarmigan suffer in proportion. In scores of ways—often very subtle—the swaying balance influences the surrounding fauna and flora.

Careful watch should be kept on changes in the feeding habits of birds, for these may rapidly give rise to serious results. Thus the depredations of the kea parrot in New Zealand have been already referred to, and large numbers of sheep have been destroyed in California of recent years by an exaggerated carnivorousness on the part of magpies. Since the beginning of the 20th century the herring gull and the lesser black-backed gull have enormously increased their ravages on agricultural land in the north of Scotland. In the harvest time they settle on the sheaves and gorge themselves with grain. They work systematically along the rows of turnips, gouging out the interior, besides making wounds which open the way to fungoid attack. In many cases a change of diet follows a rapid increase of numbers.

Interrelation of the Food Supply.—A few instances of intricate interrelations may be given. Liver-rot in sheep is due to the presence of the fluke-worm (*Distomum hepaticum*) in the liver; the larval stages are parasitic in the small water-snail (*Limnaea truncatula*), whose numbers are reduced by such birds as the pied wagtail. Similarly, water-birds check the increase of various water-snails (*Planorbis*, *Melania*, *Isidora*, etc.) which are the vehicles of the young stages of the serious human parasite known as Bilharzia. Bubonic plague in India, due to *Bacillus pestis*, often begins in mills, where the workers eat their frugal meal in the courtyard. The "crumbs" attract rats, in whose blood the bacillus is at home. A rat-flea, with fouled mouth-parts, leaves the rat and infects man with its bite. But if there was a dove-cot, whose inmates would promptly look after the crumbs, there would be fewer rats and less plague. Darwin tells of the large clodlet he took from the leg of a red-legged partridge (*Caccabis rufa*): "The earth had been kept for three years, but when broken, watered and placed under a bell-glass, no less than 82 plants sprung from it; these consisted of 12 monocotyledons, including the common oat and at least one kind of grass, and of 70 dicotyledons, which consisted, judging from the young leaves, of at least three distinct species." Small animals also, such as water-fleas, water-mites, wheel-animalcules, sponge-gemmules, and even small bivalves like *Sphaerium*, are often transported on the feet of birds from one pond to another.

Parasites.—Along with interrelations the parasites of birds must be included. The most important ectoparasites are: (1) the biting-lice or Mallophaga which feed on delicate portions of the feathers; (2) the quite unrelated true lice, belonging to the order Hemiptera, which suck blood; and (3) the skin-mites and scale-mites belonging to the Acarine order of Arachnida. Among endoparasites, besides microscopic Protozoa, such as the Trypanosome found in the blood of owls, there are frequent representatives of the three great classes of parasitic worms. Thus the Trematodes may be illustrated by *Distomum macrostomum* in various Passerine birds; the Cestodes by *Taenia anatma*, the common tapeworm of the duck; and the Nematodes by the transparent *Trichostrongylus pergracilis* of the grouse. The three examples mentioned live in the food-canal, but other organs of the bird's body may be affected. The abundant Nematode of the grouse may serve to illustrate the important point that numerous parasites may be present without doing any appreciable harm. Every grouse has hundreds of these minute threadworms, but a mutual *modus vivendi* seems to have been established between parasite and host. On the other hand, if the grouse should be enfeebled by continuous bad weather, by lack of food, or by close inbreeding within a weak stock, then the parasites may multiply enormously and bring about fatal results in the body.

Some parasites occur in several different kinds of birds, but it is more common to find a particular species of parasite in a particular species of bird. This seems to illustrate the part that isolation may play in the establishment of a species. A bird's parasites are adapted to it and cannot readily pass to a different kind of bird. Moreover the infection of the bird is usually bound up with specific feeding habits. On the other hand, there is need of cru-

cial experiments to test whether the successful transference of a parasite, say a Nematode, to a new host may not be followed by the modification assumption of structural features at present regarded as inborn and specific characters of another species.

REPRODUCTIVE HABITS

Any treatment of the problems connected with territory in bird life must begin by pointing out that relevant data are still meagre, and that theories put forward remain to be adequately tested by criticism and by work in the field. The far-reaching nature of these problems has only very lately been appreciated, and attempts to deal with them are in an elementary and almost chaotic state. To analyse in detail the conflicting views would be a protracted task, and would throw little light upon the subject, since these are often hasty statements which cannot hold their ground for long. The method here adopted, therefore, is first to give a tentative sketch in the light of what is at present known, and then to summarize briefly the data on certain relevant points.

Sociability.—Some birds are solitary in their mode of life, others tolerant, and others more or less sociable. With many species sociability is at its lowest ebb during the breeding season, when the flocks or parties break up and settle in pairs, dispersed over the country. But with others, particularly sea-birds, the reverse holds good; their scattered members rally from all directions to particular points where they breed in massed colonies, often so dense that they hardly leave room to tread. These are not simply manifestations of a communist or an individualist temperament; they are solutions of the economic problem which, in one form or another, every species has to meet. This is well illustrated by the case of finches which live on seeds themselves, but feed their young entirely upon insects. In winter they are sociable, living in mixed flocks; in spring a revolution takes place, and they are found everywhere in pairs, occupying compact territories from which all others of their kind are jealously excluded. Their character has not changed its mould, but the new economic problem of rearing a delicate brood consuming its own weight in small insects every day has temporarily imposed upon the species a different manner of life.

Once this pressure is relaxed the social instincts reassert themselves, and the family parties, renouncing a fixed territory, begin to drift together into flocks again. Where the supply of food in the breeding season is more concentrated, or the foraging range more ample, obstacles to breeding in colonies may disappear.

Conditions Governing Distribution.—The fundamental law involved may be stated thus: the breeding organization of a given species in a given locality varies in direct ratio to the abundance of accessible food-supply. To take the simplest possible case, a hypothetical falcon feeds entirely upon birds. Each pair has an effective foraging range of x square miles around its eyrie and k victims are required per season to enable a brood to be reared. If the bird population of x sq m were as low as k it might theoretically be possible for the falcons to make a clean sweep, rearing a brood at the cost of depopulating the area. Obviously that could only be done once, and would be no more to the ultimate advantage of the falcons than of their prey. In order to maintain themselves indefinitely the falcons must confine their demands to the annual surplus of potential victims. In practice the relationship between the falcons and their prey is stabilized within that margin of safety. This is due partly to the fact that an increased toll leads to increased wariness and more difficult hunting, but above all to the territorial system, which operates to "safeguard the standard of living." There is therefore, a third factor to be con-

sidered— y , the number of victims per season which the population of x sq.m. will yield over an unlimited period. This naturally varies in proportion as the population itself varies. Clearly, if y is smaller than k the requirements of the falcons cannot be met, and no breeding pair will be sustained. Once $y = k$ a suitable territory for a pair of falcons is available (the breeding site and freedom from human persecution being assumed). This territory must be kept inviolate; should a second pair begin to poach upon it, or to usurp a part, the food resources will prove incapable of standing the strain. If $y = 4k$ there will be room for 4 pairs of falcons each with a territory of $\frac{1}{4}x$ sq.m.; if $y = 10k$ for 10 pairs each occupying only $\frac{1}{10}x$ sq.m., and so on, for x sq.m. is the maximum area that the species is physically capable of hunting over, and an ideal territory will be well within that margin. But nesting accommodation is limited, and as the increasing abundance of prey gradually relaxes the struggle for existence the native fierceness of the falcon ceases to be so readily stimulated. A point is reached where territory is no longer strictly held, and tolerant individualism supervenes, several pairs foraging over the same ground without serious friction and even breeding side by side where suitable sites exist with convenient access to an abundant food-supply. The final stage is reached where $y = \text{not } k$ but, say, $100k$. In this case there is enough food for 100 pairs of falcons within the effective range of one. It will therefore be unnecessary for the young of the original pair to be expelled from the territory as they grow up. On the contrary they will remain, thriving on the abundant resources, and some sort of colony of falcons will arise, subject to a numerical limit of roughly a hundred pairs. There will, so far as is known, be no direct sanction for enforcing this limit, such as the territory system imposes upon individual pairs, but if the colony seriously exceeds it the increasing drain will begin to tell upon the victims, or actually drive them away, and stringency of food resources will drastically redress the balance—not by actual starvation, but by forcing a sufficient number of falcons to seek quarters elsewhere. In practice, clearly k would represent a considerable number of birds, and the immense concentrated population required to yield anything like $100k$ would only rarely be found. But if the food of the falcon were, say, grasshoppers instead of birds the demand would be much more easily satisfied, and it is actually among birds of prey feeding chiefly on insects, very small mammals and fishes that large communities usually occur, those depending upon the higher forms rarely passing beyond tolerant individualism.

Mutatis mutandis the same conditions apply to all birds, for scientifically considered all are equally birds of prey. Thus the British robin (*Erithacus rubecula melophilus*), which inhabits woods, gardens and hedgerows, has a food-supply consisting of such minute insects, and so limited in proportion to its effective foraging range and the susceptibility of its nestlings to exposure, that it is forced by economic pressure to adopt strict territory, from which all other robins are excluded. In autumn and winter males and females hold separate domains, which often adjoin, and may be fused as the breeding season approaches to form a territory for a pair. The cosmopolitan starling (*Sturnus vulgaris*) is an example of a species of wider foraging range and more catholic diet, nesting in cavities not abundantly available, which commonly adopts the solution here called tolerant individualism, though for all other purposes gregarious. There may be several pairs breeding on a single house and bringing food from the same meadow; they work independently and almost ignore one another's presence. The rook (*Corvus frugilegus*) differs in maintaining the community intact through the breeding season, many nests being built on a single tree or in adjoining ones, their occupants working in company and combining to repulse an enemy. Individual pairs attempting to build independently within the communal domain are at an obvious disadvantage, and their nests are liable to be destroyed. Often the formation of communities may be brought about by restriction of breeding quarters, as in the case of the cosmopolitan sand-martin or bank-swallow (*Riparia r. riparia*), or of the gannets and petrels, which breed on rocky islets.

The bird population and the manner in which it is distributed at various seasons are therefore controlled within fairly narrow

limits by the amount of suitable food available and the periodic demand for nesting sites. But it is not to be supposed that such fundamental considerations are in any sense perceived or acted upon by the birds themselves. They do not, for example, settle the extent of their territories by elaborate calculations regarding the amount of food these may be expected to yield after the young are hatched.

Song and the Selection of Territory by the Male.—The process, which has been most clearly analysed by Eliot Howard in the case of the English buntings, is much more primitive. In spring, in response to some internal organic change, the males of these species begin to isolate themselves from the flocks in which they have spent the winter. This isolation is at first only partial; each male continues to roost and feed with the flock but retires with increasing frequency to a particular domain, consisting say of a strip of hedge and its surroundings, or a patch of scrub, where he sings persistently and drives off other males of the same species. The true song, uttered at the top of the voice, is closely associated with territory-holding, and is rarely or never delivered in a finished form unless the singer is on or in search of a private territory. It is not to be confused with the low inward sub-song or undersong, sometimes called *recording*, which is uttered indiscriminately by females and birds of the year as well as by males assembled in winter flocks when singing in chorus. While there are many examples intermediate between these two, whose significance is a controversial question (they may simply express *joie de vivre*), it is no longer open to doubt that song in its most highly developed forms has the effect of proclaiming ownership of territory, thereby warning rivals that there is a prior claim on the ground, and informing females that an eligible male is in possession. It has therefore a double biological value in obviating the waste of energy involved in needless collisions—for no male will approach the singer except deliberately to offer battle—and in attracting mates, for it is undoubtedly the females which wander most in search of mates, the males being tied to their territories. The acceptance of this view involves abandoning the old vague definition of song from a musical standpoint, since all performances having the same purpose must fall in the same class. Thus larks and pipits, for example, sing as they fly, using a particular style of flight reserved for that purpose; the appeal to the eye and the appeal to the ear can only arbitrarily be separated. And just as the hidden nightingale appeals to the ear alone, so apparently other territorial species appeal to the eye alone, such birds which always occupy prominent observation posts. The soaring of birds of prey may sometimes serve a similar purpose.

How the Extent of a Territory Is Determined.—By degrees contact with the flock is relinquished, and the male spends all his time in the chosen territory, where by wandering restlessly about he rapidly develops a customary "beat," and a favourite singing stand. Till rival males settle in the vicinity this force of custom is the only limit to his boundaries. He is constantly patrolling them without knowing why, and on meeting a rival he is impelled to drive him away. But the strength of this impulse fluctuates; if the clash occurs on the very outskirts of the territory and happens to be nearer the chosen nest-site of the invader, the invader will probably carry the day, for the full powers of resistance are only stimulated when the nest-site and the immediately adjoining area vital to the food supply of the young are at stake. On such provocation a bird appears to become almost invincible against members of its own species. This accounts for the fact that while outlying parts of territories are often lost, and even whole territories change hands before breeding begins, it seems exceedingly rare for a pair with a nest and eggs to be deprived of their domain by birds of the same species, however severe the pressure. Thus the size of the territory may be reduced by competition to the minimum essential to the safety of the brood, but it cannot be reduced indefinitely. That such psychological reactions are in some way linked with the question of food supply seems clear from the fact that a sudden extraordinary local concentration of prey like a swarm of locusts, a plague of mice, or a rise of may-fly, will at once cause a rush to the spot on the part of species interested and a complete local breakdown of any territorial system that has

previously been in force. Immediately it becomes more profitable to fetch supplies for the brood at a distance than to collect them on the home domain the most exclusive species will temporarily change their mode of life. It becomes both impossible and unnecessary for those in possession of the scene of plenty to expel the host of trespassers attracted by it, and on the other hand the foragers have no more concern in maintaining the integrity of their own territories when there is better hunting outside them.

The Adjustment of Territory Under Economic Pressure.—Territory has therefore to be understood not as a rigid system of partition into small areas each occupied by a jealous pair, but as a delicately adjusted balance created and maintained by economic pressure and varying greatly in its details from time to time and from place to place according as the pressure varies. For the sake of clarity the foregoing sketch has had to be given a rather simpler and more clearly defined shape than is often found in practice; it is merely intended to illustrate some of the principles upon which territory is based, and must not be taken as immutable law or exhaustive treatment. There is, for example, a considerable proportion of non-breeding birds, fluctuating from season to season, and generally largest in the case of the larger species, which are slow in coming to maturity. In the case of such migrants as many storks, terns and gulls, immature birds often remain throughout the breeding season in the winter quarters of the species, while others accompany the adults. But apart from immaturity it is undoubtedly common for fully grown specimens quite capable of breeding to fail to do so. Some of these remain in flocks or parties, wandering about over ground where no territory is held by pairs of their own species. A large number of males take up territories, but are so late in doing it, or so unfavourably placed, that they fail to attract a mate, and often desert the territory in search of one. It is from this class that solitary birds noticed in towns, or away from their natural environment, in the height of the breeding season are frequently drawn; it is also, among songsters, responsible for an utterly disproportionate share of the bird-music of that period. The hens, with no obligation to tie themselves down to a territory, wander much more freely, and both sexes seem always ready to fill at a moment's notice any vacancies occurring through misadventure among the mated birds. While satisfactory data respecting the ratio of non-breeding to breeding stock have yet to be secured this is undoubtedly an important factor, amounting in ascertained cases to as much as 40 per cent.

That different species compete with one another for food is clear, but except with regard to nesting sites the frequency and manner in which this rivalry finds vent are still uncertain. The raven (*Corvus corax*) and the peregrine falcon or duck-hawk (*Falco peregrinus*) are almost world-wide forms which often hold overlapping territories and come into collision with one another freely. But there are probably few species which coincide in range and have a diet and breeding habits so nearly identical that rivalry between the two is as severe as between members of a single race. No doubt rivalry is more often potential than effective; it is not in practice a question of "taking the bread out of one another's mouths," but simply of a situation from which such a crisis would rapidly develop if the existing checks were removed. In averting such a state of famine, enemies are of the greatest biological value to a species. The dominant forms on a given area will therefore comprise a community whose activities are partly complementary, partly competitive. The study of such interrelations is the subject of Ecology (*q.v.*). There is however one aspect to be dealt with here—that of bird population.

BIRD POPULATION

During 1890-1901 F. L. Burns carried out a sectional bird census at Berwyn, Chester County (Pa., U.S.A.), and reported 588 pairs of native birds and 106 of English sparrows (*Passer domesticus*) on one square mile of ground. Since that time a certain amount of work has been done on both sides of the Atlantic, but data are still unsatisfactory for purposes of generalization. The available British results are fairly accurate and complete but very few, while the American are more copious but less

reliable. In the summer of 1907 S. A. Forbes found an average of 600 native birds per square mile in southern Illinois, which was less than half that obtained by the later national census. He estimated for the whole State 114 English sparrows per square mile, but a large number of these were young. In 1914 F. L. Burns repeated his census at Berwyn and got 617 pairs of native birds on the area which had yielded 588 at the opening of the century—a density still below one pair to the acre.

United States Bird Census.—In the same year the national census obtained data on a large scale for the north-eastern States and much more sparsely for the remainder. Observers were not always competent, and they sometimes misunderstood instructions. Nevertheless it was considered possible to work out a preliminary average for the States north of North Carolina and east of Kansas, the figure arrived at being 119 pairs per 100ac. for farms and 175 per 100ac. for woodland. In 1915 the average for farms rose to 125 pairs, and the average for woodland to 190. The Plains region from Oklahoma to North Dakota reported 125 pairs per 100ac.; the average of all counts from the southern States was 76 pairs of 23 species on 58ac.; and in all States east of the 100th meridian density of farms was roughly 125-131 pairs per 100 acres. While the averages were therefore in reasonably close agreement the separate areas varied greatly; 40ac. of native prairie in South Dakota supported only 12 pairs, and 80ac. in Kansas only 31 pairs (or 40 per 100ac.) while a 40ac. farm with orchards adjoining the latter had 49 pairs of the same species, yielding a density over three times as high. Virgin land in Colorado gave a figure as low as five pairs per 100 acres. Toward the other extreme a 52ac. peach orchard in Ohio held 150 pairs, a 40ac. farm in Connecticut 188 pairs (including eight of sparrows and 15 of starlings) while under strict protection eight ac. at Olney, Ill., were made to hold 70 pairs of native birds, and five ac. near Washington (D.C.) possessed 135 pairs of 24 species (including a colony of 74 pairs of purple martins). An 80ac. tract at Albany (Mo.) held in 1914 298 pairs, and 23ac. of built-up village area at Chevy Chase (Md.) showed 148 pairs of native birds and 13 of English sparrows, the most numerous being the American robin with 10 pairs. The 256ac. campus of Cornell university at Ithaca (N.Y.) gave sectional densities ranging from 104 to 412 pairs per 100ac. with an average of 225, 56 of these being house-sparrows. An average of all reports for two years gave seven pairs of American robins and five and one half of English house-sparrows over all farms covered; Burns estimated the number of house-sparrows in the United States east of the Mississippi at 165,000,000.

It will be clear from what has been said about territory that the reliability of these figures is seriously compromised by the fact of their being expressed in pairs instead of individuals. To assume, as was here done, that a singing male represents a pair is to beg an important question; there is no doubt that the males of many species reduce their volume of song, or actually discontinue it, at a fairly early stage. A large proportion of song delivered at the height of the breeding season is the product of unmated males. Such a census implies, moreover, that all birds secure mates every season, which is far from being the case. The same criticisms apply to some of the European data, next to be considered.

European Census Results.—R. J. Ussher and R. Warren (*Birds of Ireland*, 1900) made an incomplete but interesting attempt at an inventory of Irish heronries, which suggests that the number of breeding herons per 10,000ac in Ireland at the end of the 19th century was between three and nine, so that the total population might be estimated at about 20,000 birds. H. Boyd-Watt, in a series of papers (*Ann. Scot. Nat. Hist.*, 1908-14) put the number of heronries in Scotland including four or more nests at about 190. Reference should also be made to the full census of British heronries undertaken during 1928 (*British Birds*, vol. xxii).

C. J. and H. G. Alexander found, in 1908, 555 pairs of migratory birds breeding on eight sq m. at Tunbridge Wells, and 260 pairs on four sq m. at Wye, Kent. In the first case the willow-warbler, *Phylloscopus t. trochilus* (188), whitethroat, *Sylvia c. communis* (101), chiffchaff, *P. c. collybita* (56), and tree-pipit,

Anthus t. trivialis (55), were considerably the largest items; in the second the willow-warbler (88), tree-pipit (35), whitethroat (30) and nightingale, *Luscinia m. megarhyncha* (25). E. M. Nicholson on a 40ac. estate near Haslemere, Surrey, obtained in 1926 a summer population of about 200 adult birds, all those which bred upon or habitually foraged over the area being included. They reared altogether about 453 young, the proportion of fledglings varying considerably with the species. The main items were: chaffinch, *Fringilla c. coelebs* (35 adults and 49 young); British robin (30 a. and 45 y.); willow-warbler (29 a. and 35 y.); blackbird, *Turdus m. merula* (26 a. and 35 y.); starling (16 a. and 37 y.); song-thrush, *Turdus philomelos clarkei* (14 a. and 21 y.), and hedge-sparrow, *Prunella modularis occidentalis* (12 a. and 27 y.). A third of the breeding stock consisted of summer migrants, but the winter (December) population of this same area was hardly changed at 258, of which finches numbered 80 (two per ac.; chaffinch and lesser redpoll, *Carduelis linaria cabaret*, each 32); titmice 74, woodpigeon, *Columba p. palumbus*, 21, and starling 13. B. D. Nicholson by a monthly census of 20ac. of private grounds at Alloway near Ayr, Scotland, obtained on Jan. 23, 1927, 136 birds; on Feb. 20, 262; on March 20, 213; on May 1, 236, on May 29, 230, and on June 29, 209. In January the dominant species were the blackbird (30), chaffinch (28) and blue titmouse, *Parus coerules obscurus* (24). The sharp rise during the next month was accounted for mainly by an increase of 68 chaffinches; on May 1 the chaffinch still showed 47, and on May 29, 46, or more than two per acre. The rise of the thrush from 0 in Jan. and eight in Feb. to 36 in May, and of the greenfinch, *Chloris c. chloris*, from 0 to 24 in the same period, together with the decline of the blue titmouse (Jan., 24; Feb., 45; May, 5; June, 0), were the most striking fluctuations. The general density of about 10-12 birds per acre may be taken as a typical figure for such compact and highly favourable areas; adding the next in order of numbers (starling and British robin) the dominant species are equally characteristic. In Kensington Gardens, London (an area of 275ac., where feeding on a large scale has produced a highly artificial bird community) far higher winter densities are recorded, and the average for the whole area in November worked out at 14.47 birds per acre.

On agricultural land the population, as a rule, is much more sparsely distributed. The Oxford bird census, by repeated counts during 1927-28, obtained winter densities of one-two birds per acre and a summer total of 444 on 231.6ac., the dominant forms being blackbird (75), chaffinch (58), thrush (36), whitethroat (24), and British robin (22). But on fallow in autumn, concentration of finches, skylarks, etc., produced densities over limited areas of over 30 per acre. On rough grass-land extending over 153ac. of the South Downs near Seaford, Sussex (with some low scrub, chiefly gorse), J. F. Thomas carried out a bird census 20 times during Oct. and Nov. 1927, the density fluctuating between 0.11 and 4.44 per ac. with an average of 1.24. The detailed results showed that, at any rate in certain localities, the numbers and proportions arrived at for the various species might vary widely according to the day on which the census was taken. Only those counts which are confirmed by several checks can be accepted as satisfactory.

Gamebirds and Birds in Sanctuaries.—More data are available in the case of species shot for game or protected in sanctuaries. It is estimated that the number of breeding pairs of herring gulls (*Larus argentatus*) on the German North sea coast rose from 5,000 in 1906 to nearly 18,000 in 1923. The rise seems to have been general and is not attributable to the establishment of state sanctuaries, which harboured only 7,000 of the 1923 stock. Nevertheless, the multiplication of gulls at the expense of other species was in certain cases very marked; on Memmert the 1906 population of 550 breeding pairs included 80 of herring gulls and 400 of various species of tern, while the 1923 population of 9,700 pairs included 5,500 of herring gulls and 4,020 of terns. These figures were obtained with a high degree of accuracy by marking the nests with numbered pegs; a system which had to be discontinued elsewhere on account of the disturbance involved.

In the Alps of Dauphiné (south-east France) a sectional census by E. M. Nicholson during July-Aug. 1927 resulted in density varying from approximately 0.4 birds per 100ac. in barren valls between 7,240ft. and 10,500ft., to 7.8 in the zone between 5,300 and 5,700 feet. The general distribution was two to four birds per acre between 2,370ft. and 5,000ft.; about six per acre for 5,000ft. and about 0.05 per acre above 6,000ft.

Population and Rate of Reproduction.—From all available figures it appears that the bird populations of Europe and North America are remarkably similar, having a general average of large areas of one-four birds per acre, with a handful of species dominant. Satisfactory data from other parts of the world is wanting. Bird population tends to be lowest on wide tracts with sparse cover, and highest in small pockets formed by orchards and homesteads, open towns or villages, lakes, sea-cliffs, and other obvious points of concentration. In such extreme cases rookeries of the Adelie penguin (*Pygoscelis adeliae*) a density above 250 per acre may be maintained over as much as 30 sq. mi. but an upward limit is invariably set by the quantity of accessible food resources.

Other factors besides food-supply may limit or frustrate reproduction. A. L. V. Manniche (*Meddelelser om Grenland*, xl 1910) found that in north-east Greenland during the highly favourable summer of 1907 the entire sea-bird population migrated early without having been able to breed. The king-eider (*Somateria spectabilis*), paired and took up territory, "but signs of open sea water appearing as yet the birds assembled small flocks instead of building their nests, roving about for some days in the fresh waters and leaving the country at last altogether." In all regions bad weather at a critical period may destroy a large part of the product of the breeding season, and beside such catastrophes there is abundant evidence that fertility and mortality among young birds, before and after hatching, vary considerably according to locality and season. Clearly in the case of a more or less stationary population the number of eggs laid per annum must approximately equal the number of deaths from all causes. Among nidicolous young the losses at an early stage are very heavy. Thus B. D. Nicholson on the 20ac. at Alloway already described, observed, during 1927, 156 nests containing 687 eggs (disregarding those in which no laying took place). Of these only 420 were hatched and 300 fledged. Other British statistics, which are very few, show between 40% and 60% eggs laid as being destroyed before fledging, and a similar rate of loss is probably maintained until the young are able to fend for themselves. In an average year, apart from migration, the bird population at the end of the breeding season is probably on about double what it was at the beginning. In tropical countries there is no definite breeding season, nests of many species being met with in every month of the year. J. P. Burkill, in the case of the British robin, shows reason to believe that not more than 0.8 young per pair survive till the following breeding season.

Longevity.—Most small birds breed at the end of their first year, and appear to have an average life in a wild state of between two and six years. Marked swallows (*Hirundo rustica*) have on more than one occasion been recovered at nine years old; gulls, plovers, ducks, herons and other larger birds frequently exceed this span. A certain great skua (*Catharacta s. skua*) at Herma Ness sanctuary, Scotland, is said to have lived there at least 32 years, and birds-of-prey are undoubtedly capable of still longer life. There is a satisfactory record of an eagle owl (*Bubo b. bubo*), still living in captivity at 68. But with the great majority of species generations are short and turnover rapid. The sex ratio is near equality, except in the case of polygamous species (various gamebirds, etc.), and a few like the European cuckoo (*Cuculus canorus*), which are polyandrous or promiscuous. Guthrie-Smith (*Bird Life on Island and Shore*, 1925), has shown that the dark southern skua or Sea-hawk (*Catharacta roenbergi*) breeding on islands off New Zealand, frequently if not habitually forms households consisting of two males and one female.

BIRDS, MIGRATION OF. The broad fact of the seasonal journeys of birds is a matter of common knowledge, and has been recognized from very ancient times. The author of the Book of Job wrote of the hawk that stretches her wings toward the south; Homer wrote of the flight of the crane and Anacreon of the return of the swallow; primitive peoples have used the names of migratory birds for the months in their calendar. Latterly, also, the theoretical problems presented by migration have attracted the interest of biologists, and a knowledge of the facts has become of real practical importance in economic ornithology. Yet today, after untold centuries of popular knowledge and many years of more deliberate investigation, there still remains much about migration which is unknown.

Some part of this ignorance is due to the difficulty of observing migration. In most regions very little is to be seen of migration actually in progress. The observer may note the annual reappearances and disappearances of many species, and in autumn the "flocking" which often precedes departure. He may also, but less readily, note the fluctuations in the numbers of other species which are never wholly absent. Only occasionally, as a rule, will he see birds arriving on the coast from over the sea.

Much migration takes place by night, and this even in the case of species which are wholly diurnal in their ordinary habits. Nocturnal migrants may sometimes be heard calling overhead, but they are, naturally, rarely to be seen except when the lantern of a lighthouse exercises that fatal attraction, usually in misty weather, which lures so many to destruction. Otherwise, there is merely the sudden presence one morning of species not previously seen, or the disappearance of others. Mere fluctuations of numbers cannot easily be gauged, except at some favoured island or other isolated station where the resident bird population is negligible and large numbers of resting migrants are concentrated within a small area. On occasion, nevertheless, great diurnal movements are visible, and the steady procession of vast flocks of birds forms an extraordinarily impressive sight.

Methods of Study.—With this initial difficulty of observation, scientific investigation of migration is seriously handicapped. Even where opportunities for observation at a particular place happen to be good, the results are difficult to interpret: mere local observation can obviously never give a satisfactory picture where distance and movement are of the essence of the matter. Much can be done, and has been well done in both Europe and America, by concerted schemes of observation in which simultaneous records from many localities over a wide area are collected and correlated. Although this method has been fruitful, and has provided the main basis of present knowledge, it still leaves some aspects of the question almost untouched.

Of late years a supplementary method has been greatly developed which approaches the matter from a different angle, that of the individual bird. This consists of marking birds in large numbers for the sake of the information obtainable from such of them, necessarily only a small percentage as a rule, as may subsequently come to notice. Birds are marked either as nestlings still unable to fly, or as adults caught for the purpose in some non-hurtful way. The usual mark is a small aluminium ring or band resting lightly on the foot. The ring bears an address to which the finder can report, and an identification number which enables the date and place of marking to be traced from the original record. Marking is especially valuable in, so to speak, disentangling the movements of individual birds, typical of those native to a particular region, from the vast and complex movements of the species as a whole which can otherwise be observed only in the mass. The method has already yielded much interesting information of an accurate and definite kind not obtainable by other means, and its further employment should result in important additions to knowledge.

General Principles.—Migration consists essentially of an annual cycle of movements between two alternative habitats. Of these, the summer habitat provides the special opportunities which are necessary for the breeding season, but becomes too inhospitable in winter. The other habitat suffices for the purposes of ordinary life in winter, but is presumably inadequate for the more exacting requirements of the breeding season. Alternation between the two, made possible to birds by their great mobility, is thus related both to the seasonal changes in the respective environments and to the different needs of the bird in the reproductive and non-reproductive phases of its life.

It is a general rule that a bird breeds in the coldest part of its range. The breeding area of a species is usually clearly defined, and individual birds, as marking results have amply shown, commonly return to their native localities in successive years. In some cases the winter area may be almost or quite as definite: in other cases it may be more vaguely circumscribed, and in some instances the annual movements seem to be mere wanderings in which the breeding place is the only fixed point.

Geographical Aspects.—In the comparatively constant conditions of the tropics many species are wholly stationary. In high latitudes the winter conditions are so severe as to make migration a necessity for almost all birds. Intermediately in temperate climates, migration in some degree is the rule and wholly stationary species are in a minority.

Migration is in some cases no more than a descent from high ground to the neighbouring valleys, or a movement from an inland area to the adjacent coast. In other cases an entire region may be deserted in favour of another at any distance up to several thousand miles and possibly separated by wide seas. Migration from high latitudes, furthermore, may carry the birds across the equator into the temperate regions of the other hemisphere. Many birds from the northern hemisphere thus winter in the summer of high southern latitudes, leading their non-reproductive life during what is the breeding season for birds native to these parts: it so happens that there is scarcely any counterpart to this in the case of birds breeding in the far south.

Different species of birds have different needs, and what serves as a winter area for one may be suitable only as a summer area for another. Thus in a temperate region there are so-called summer visitors and winter visitors. There is no difference in principle, but the observer is so placed as to see the two migrations from different angles. Other species he sees only as birds-of-passage, twice a year, on their journey between widely separated summer and winter areas. In still other cases the two areas of a species are adjacent or partly overlapping, and the winter area may even lie wholly within the wider summer range. When there is overlapping, the species is present throughout the year, although some or all of the individuals are migratory. Even individuals of the same species and native to the same locality may differ, some being stationary and others migratory. Furthermore, immature or other non-breeding individuals may sometimes linger in the winter area during the summer.

Seasonal Aspects.—Although the movements of migration are described as taking place in autumn and in spring, they are by no means restricted to two short periods. Some species move sooner than others, and individuals from different parts of the range may also differ widely in the times of their migration. The arrival even of a single species in a particular area is usually spread over a considerable period, and the performance of the journey itself also takes time. With all these differences, migration as a whole is spread over the greater part of the year. The latest arrivals in the highest latitudes complete their northward journey only a little before midsummer, by which time some young birds of earlier species further south are almost ready to leave. Autumn migration is on a grander scale than spring migration, with the number of birds at its maximum after the breeding season. The autumn movements also tend to be more leisurely and protracted, and they are often supplemented by weather movements which accompany specially severe conditions during the winter: these may almost overlap the first spring movements in the opposite direction.

Irregular Movements.—Passing reference may be made to certain erratic migration phenomena which are exceptional in that they do not occur annually. This is apart from the question of late weather movements which may be regarded as irregular extensions of the ordinary autumn migration, and from the variable wanderings of some species in which migration is not developed to a pitch of regularity. The most remarkable case is that of Pallas's sandgrouse (*Syrhaptes paradoxus*), a species normally native to central Asia and the extreme south-east of European Russia. It is not ordinarily a great migrant, but at intervals of several years an "irruption" takes place in spring in a northwesterly direction. Numbers are then recorded throughout Europe, and the species may attempt to breed in the new countries which it thus reaches. Most of the birds perish, however, and the evidence of a definite return movement is slight. Other examples are known both in Europe and in North America: most of these consist of autumn movements of unusual magnitude and extent which are performed by certain species at irregular intervals of several years.

Altitude, Velocity and Duration.—Contrary to former belief, migrants do not fly at great altitudes, but generally keep within 3,000ft. of the ground, and often close to the surface of the land or water. Great heights above sea-level are of course reached when high mountain-ranges are crossed, but otherwise only exceptionally.

On migration an unhurried, steady speed is usually maintained, the ordinary flight of the species and not the accelerated velocity of which it is capable over short distances in emergency. The total journey performed by an individual bird may be anything up to several thousand miles: marked swallows and storks from northern Europe, for instance, have been recovered in South Africa, a distance of some 6,000m., and this must be exceeded in some cases. How long a flight is performed at a single stage is difficult to determine. Probably about 200 miles, in a day of from six to eight hours' actual flying, is not unusual. Some sea-crossings, however, involve more sustained efforts: the Pacific golden-plover (*Charadrius dominicus fulvus*) is credited with an uninterrupted flight of some 2,000m. from Alaska to Hawaii, without possibility of rest near the direct route.

Routes.—Migration does not necessarily take place in a north and south direction, although that is the general tendency. In Europe, for instance, much migration follows a diagonal course; and some even proceeds on an east and west line, a more temperate winter being found on the Atlantic seaboard than in equal latitudes further east. The general directions of the main streams of migration in different parts of the world remain the same from year to year. These directions may nevertheless be widely divergent, in any region, for different species or even for different individuals of the same species.

In spite of the constancy of the general directions of movement, it is probable that too much has been made in the past of the idea that migration is restricted to definite narrow routes. Coastlines are certainly followed to a large extent, and much migration may be observed in the valleys of great rivers, but it is equally true that stretches of land or sea are often traversed on a wide frontage. Whether the fly-line of the individual migrant is more precisely determined in the one case than in the other, or whether there is merely a great concentration of fly-lines along certain geographical features, is not known.

Sex and Age Differences.—The males of many species tend to be rather earlier than the females in reaching the summer quarters in spring. In the autumn the migration of young birds is in many cases earlier than that of the adults, although this is by no means the rule for all species. In the special case of the common cuckoo (*Cuculus canorus*) of Europe, the reverse order is notably exhibited: the adults take their departure very early, while the young are reared by foster-parents of other (and often non-migratory) species and do not leave until later.

Weather Influences.—While a general relationship obviously exists between the events of bird-migration and the annual cycle of the seasons, it has been disputed whether there is any close correspondence between particular migration events and day-to-

day weather changes. There is, however, much good evidence, both European and American, that the weather conditions prevailing in the area of origin of a movement have an important influence. If favourable conditions exist at the starting-point at the proper season, a movement will take place therefrom irrespective of the conditions prevailing at the goal or in the area in which the latter part of the journey must lie. In north-western Europe, for instance, emigration is favoured by anti-cyclonic pressure conditions, with settled fine weather and light winds: this applies both to the autumn and to the spring movements, and the mere direction of the wind is unimportant. Temperature, also, has an influence, a falling temperature in autumn and a rising temperature in spring being favourable to the inception of a movement. The maximum effect is obtained when both the barometric pressure and the temperature are favourable, and when this follows a period of adverse conditions during which migration has been retarded. Movements thus tend to begin when the weather is good at the starting-point, but storms may nevertheless be encountered on the way, leading to delay and loss of life; and it sometimes happens that very unpropitious conditions are found at the end of the journey, as when summer visitors arrive in a spring snow-storm. Fog is a serious hindrance to migration and leads to loss of direction and to delay.

Vastness, Complexity and Regularity.—From a general consideration of the known facts of bird-migration, one receives an impression of vastness of scale. Thousands of species and millions of individuals take part in migration. The movements in total are almost world-wide, and even the journeys of individual birds are often of great length. There is almost no time of year when some kind of movement is not in progress. Added to this is a great complexity. Species differ from one another in the times, directions and extent of their migrations, and even within a single species there may be much difference between individuals. The directions of flight are so various that simultaneous streams of migration may cross each other at right angles or even follow opposite directions over the same course. Yet these vast and complex phenomena show a truly wonderful degree of regularity. The same arrivals and departures are annually recorded at the same times. Individual birds accurately find their former homes on returning from half-way across the world. The same general directions of flight are maintained year after year. All the events of migration, in fact, show a regular recurrence on the selfsame plan.

The Nature of Migration.—Bird-migration cannot be explained on a basis of intelligent action, on the analogy of a human being who seeks a milder climate for the winter, without assuming an analytical appreciation of the recurrence of seasonal events and a power of rational action altogether beyond anything which there is ground for considering as characteristic of the avian mind. To birds which are only summer visitors to high latitudes winter is a thing unknown for countless generations; there can be no conscious knowledge of it, and therefore no reasoned intention in the act of avoidance. The possible traditional element, the imitation of each generation by the next, is also excluded in many cases by the fact that in these the young of the year perform their first migration apart from their parents.

Nor, at the other extreme, can it be said that migration is due to the sheer compulsion of physical conditions. Although compulsion by external forces may partly explain the "weather movements" which occur late in the season and vary with the severity of the winter, true migration is much too complex and much too regular to be created anew each year by mere pressure of circumstances. The conditions are in any event quite inadequate as causes. A bird migrating southwards in July is not driven from its homeland by the advent of winter, and a bird migrating right across the tropics does much more than is necessary merely to avoid the winter rigours of its native area.

The performance of migration must be regarded as the expression of an inborn instinct, a racial custom transmitted by inheritance, and only on this basis can any approach be made to a satisfactory understanding of the facts. (The nature of instinct is, of course, itself a riddle, but it is a well known factor in animal

life and in no way peculiar to this special question.) And if it be admitted that migration behaviour is essentially instinctive, several problems naturally present themselves.

Ends Served by Migration.—The instinct must, in the first place, serve useful ends: the custom is an expensive one and would not persist if it did not bring advantage to the race. At least some part of this advantage is obvious. Migration enables a bird to inhabit two different areas at the times of year most favourable in each and suited to the needs of life at these seasons. The advantage of winter absence from high latitudes lies in avoidance of the cold and stormy weather, of the scarcity of food, and of the short hours of daylight. The advantage of return to these latitudes lies in the availability of suitable breeding-places, in abundance of food at the critical period of the year, and in the long hours of daylight for collecting it.

Origin of Migration Instinct.—The fact that the instinct is useful does not explain its existence, although it may account for its survival. A thing does not happen merely because it is advantageous that it should happen: some effective cause must operate so that the end may be attained. The instinct must have been implanted in the race in some way, and the custom probably originated in the far past as the result of some circumstance or development in the history of birds and of their distribution over the face of the earth. Possibly some great climatic change, such as a glacial epoch, acted as a compelling cause and, at the time by sheer necessity, established the custom which still persists. Possibly migration gradually evolved during the natural spread of various species from an original area of resident habitation. Or, again, it is even possible that the custom originated suddenly in one case and then another, as the result of abrupt efforts of range expansion. The resulting custom, whatever its origin, may be regarded as to some extent an annual repetition by the individual of some process or event in the past history of the race.

Annual Stimuli to Migration.—There must be a further element in the causation of migration. In addition to an origin or ultimate cause there must be an immediate stimulus or occasional cause, on the analogy of the hand which packs the explosive charge in a cartridge and the hand which pulls the trigger and so releases the pent-up force. Given the instinct lying dormant in the race, something must arouse it to activity with the recurrence of the appropriate seasons. The annually recurring stimuli which evoke the instinctive response may either be climatic or other external factors arising from the cycle of seasonal changes in the physical world, or be physiological factors arising in the cycle of alternation between the reproductive and non-reproductive phases in the bird's life. The stimuli may be a combination of both factors, if indeed these could in any event be wholly separate, with perhaps a predominance of the extrinsic element in autumn and of the intrinsic in spring. There are probably primary or preparatory stimuli of these kinds which produce the unrest which precedes migration, and secondary or effective stimuli in the form of favourable meteorological conditions which set migration in actual motion, not only at the outset but also at the beginning of each successive stage of the journey. The whole answer obviously does not lie in weather stimuli, as is shown by the fact that these are effective only when they occur at the appropriate seasons, occurring at other times without this result.

Path and Goal of Migration.—Finally, granted a useful purpose in migration, granted an origin for the instinct, and granted recurring stimuli at the appropriate seasons, there remains the great problem as to how migration accomplishes its object once the instinct has been brought into play. How do migrants find their way, and what determines the way to be found? No external physical forces exist which seem adequate as factors which could determine the path and goal of migration flight in its more highly developed forms: the bird in its journeyings is no mere plaything of chance or of the winds. The paths of migration are both constant and complex, and it would seem that a capacity for following more or less definite paths must form part of the inherited instinct. It is indeed difficult to avoid the conclusion that there is some inherited memory of the path and goal, as the

knowledge cannot be traditional or the action imitative where young birds migrate for the first time unguided. As to how the path is followed, it seems likely that vision is the sense principally concerned, even in nocturnal migration. The adverse effect of fog is an important point in favour of this conclusion, although vision may seem inadequate in the case of oversea paths. Other ordinary senses do not seem likely to be important. There is no evidence of any "magnetic sense"; and although very highly developed powers of orientation undoubtedly exist, the idea of a special "sense of direction" seems devoid of exact meaning.

The Problems Restated.—A clear appreciation of these several problems is necessary, because too often there has been a failure to distinguish the different issues involved. It is said, for instance, that birds migrate to avoid the cold of winter, and this is then illogically taken to mean that the cold causes migration. There has also been confusion between the originating cause and the immediate stimulus, as in the fallacious argument that if food scarcity can be shown not to be the annual stimulus to autumn migration it can likewise have played no part in the origin of the instinct.

To restate the position, the main theoretical problems of bird-migration are concerned with the nature of the series of factors which must be assumed to exist, as follows.—factors which make migration advantageous and thus give the instinct a survival value; factors which may in the past have helped to originate and develop the instinct in the race; factors which periodically stimulate the instinct to active expression in the individual at the proper seasons; and factors which determine the manner in which migration is actually performed. The nature of some of these hypothetical factors must perhaps always remain a matter for speculation, but progress towards the better understanding of others should become possible as further knowledge of the concrete facts of migration is obtained.

See W. Eagle Clarke, *Studies in Bird Migration* (1912), F. von Lucanus, *Die Rätsel des Vogelzuges* (1923, bibl.); A. Landsborough Thomson, *Problems of Bird-Migration* (1926, bibl.); Alex. Wetmore, *The Migrations of Birds* (1926). (A. L. T.)

BIRDS, PROTECTION OF. The protection of birds has been rendered necessary by their excessive destruction in various ways, including: (a) reckless and ignorant destruction of these creatures as well as of their nests; (b) commercial destruction for the market; (c) trade in ornamental plumage; (d) inordinate collecting of skins and eggs, especially of rare species; (e) increase of towns and population, with draining of marshes, felling of timber, etc. The extinction of the passenger pigeon illustrates (a) and (b). Fifty years ago it existed in millions throughout the United States, one town sending 11,000,000 to market in 1869. In 1908 the last individual bird was taken. (c) Extermination of the egret and the white heron in certain American States, and of other finely plumaged birds in different parts of the world, brought about the plumage acts of America (1913) and of Great Britain (1921) and numerous acts and ordinances in British dominions and colonies. A combination of causes (d) and (e) are responsible for the loss to England of the great auk, spoonbill, honey buzzard, osprey, etc.; and to other lands of equally notable species.

Protection in Early Times.—A familiar verse in Deuteronomy which forbids the taking of the mother bird with the young is the first record of a law for the protection of birds. Biblical and classical allusions to the snare, the fowler and the cage indicate at what an early period men set about capturing birds for profit and pleasure. In ancient Egypt and India certain kinds, such as the ibis and the hoopoe, were held sacred, but this had no effect upon the treatment of birds in general. Conditions in Rome during the decadence of the empire are recorded by Sulla, who describes the *ornithons* and aviaries where birds were fattened for the table or kept blinded as pet songsters. One establishment in Sabinum, he says, could supply 5,000 thrushes in one year. These things were the precursors of the *roccoli* for wholesale snaring of birds in Italy today, and of the netting of quails (amounting in one year to 1,000,000) in modern Egypt to supply European *gourmets*.

Protection was first afforded in the interest of sport or of the

nobleman's larder; game-birds became private property, and the earliest laws were framed for the purpose of reserving to the landowner the right of killing certain food-birds and of ensuring the safety of the falcon tribe for his sport. In Britain there were laws of this kind in the reigns of Henry VII. and Henry VIII., providing for penalties, with heavier punishment for the taking of certain eggs. "For two thousand years," comments an American writer (G. I. Hartley), "the birds of Europe were considered the property of anyone who desired to take them. Only game-birds were vouchsafed any protection, and they were reserved for slaughter by persons of rank."

Recognition of the Economic Importance of Birds.—In the course of centuries a growing consciousness of the bird's place in the economy of nature was forced upon men's minds. The imminent peril to food-crops should vermin and insect pests get beyond human control became apparent. Upon an increasing knowledge of this danger are based the great majority of protection laws in all lands. Practically all of these laws had their birth in the 19th century. Two definite lines of protection were thus set up and two theories of ownership in birds recognized; viz., the rights of individual owners and the rights of the community. In mediaeval times the peasant looked upon birds mainly as inimical to his interests, or merely as a source of income and food. The thinking classes began in time to view matters differently; but lack of research and of education by the State has left much of the old feeling with the country folk of to-day. "Birds are to be guarded against by the husbandman as being destructive," says the *Penny Encyclopædia* of 1788. "It is now universally recognized that birds play a most important part in checking the ravages of various animal pests, particularly in the case of insects," writes Dr. W. E. Collinge (*Food of Some British Wild Birds*, 1927).

Protective Legislation.—England almost alone among European countries, has allowed aesthetic considerations to affect legislation. The first general British statute, that of 1869, was for the protection of sea-birds, and was prompted by indignation at the winging of gulls for holiday sport and plumassiers' profit. Denmark, however, prohibited, in 1894, the shooting of song-birds throughout the year, and a Dutch law of 1837 gave special protection to nightingales. The general principle of British legislation in force in 1928, founded on the Act of 1880, is that of protecting all wild birds during the nesting season; landowners and occupiers, however, having the right to take species not scheduled by the act or the local order; and of leaving further preservation to the option of county councils. Sweden had a code as early as 1834. Switzerland (1904), Spain (1896), Belgium (1873) and Holland (1880) have prohibited the taking of useful birds; the definition of "useful," exceptions and conditions varying in accord with national feeling. Norway, whose resources depend largely upon shooting and fishing, gives no protection to birds of prey, nor did Russia under the laws of the empire. Italy, in spite of provincial laws dating back to the first decade of the 19th century, continues to slaughter insect-eating migrants for the pot. The movement in Germany began among farmers and foresters in 1869, though the Grand Duchy of Hesse had protected birds useful to agriculture since 1836. This protection was vigorously conducted there and, especially, in Hungary, on strictly utilitarian lines. The pole-trap was prohibited in Germany in 1908. It had been made illegal in Great Britain in 1904.

In all the great British dominions and colonies—Canada, Australia, New Zealand, South Africa and in India, legislation exists in the interests of agriculture, of ornithological science, and of the public in general. In Egypt much was effected under Lord Cromer and Lord Allenby. The great sanctuaries of Canada and Africa are comparable with those of the United States, a country in which bird protection has occupied a conspicuous place. In 1886 a model law was drafted by the American Ornithologists Union, protecting all birds except game (otherwise dealt with) and the English sparrow. It has been adopted, with modifications, in many States. The first State law (for game) was passed by New York in 1791. Massachusetts forbade the "wanton destruction of useful and profitable" species as far back as 1818. The Biological survey (*q.v.*) is a leading factor in Federal bird preser-

vation. In 1913 Federal law gave interstate protection to migrants. In Asia, the only considerable work has been started by Japan, which is interesting itself in the preservation of its native birds.

International Legislation.—Following national laws it became obvious that international legislation was essential to preserve migratory species. Various congresses advanced this contention. In 1900 a convention was signed in London by seven countries for the protection of animals and birds in a wide tract of Central Africa. An elaborate international convention, following a series of congresses, mainly at Vienna and Buda-Pest, was signed in Paris in 1902 on behalf of Austria, Belgium, France, Greece, Luxembourg, Monaco, Portugal, Sweden and Switzerland. This, however, was intended to procure similar legislation throughout Europe for protecting useful birds, rather than to create international obligation for the preservation of international birds. More significant was the treaty signed by Great Britain and the United States in 1916 for the protection of insectivorous species throughout Canada and the United States. Later, official conferences have been held in Washington (1926) to check discharge of oil upon the sea, with the collateral effect of saving sea-birds from destruction; and in London (1927) for the better protection of wild fowl. Another effort to preserve migrating birds is the provision of perches on lighthouses upon migration routes on the English coast, by the Royal Society for the Protection of Birds, and, by differing methods, in one or two other countries.

Above and beyond laws and conventions has been the continuous work of bird protection societies in many lands, associated with the provision of watchers and wardens to guard breeding-grounds of rare species, and with the education of children and the public generally regarding the life, habits and utility of wild birds. The oldest of such societies appear to be the English R.S.P.B., founded in 1889, and the National Association of Audubon Societies, founded in America in 1902.

(See also BIOLOGICAL SURVEY; BIRD SANCTUARIES; ORNITHOLOGY, ECONOMIC.)

(L. G.)

BIRD SANCTUARIES. The provision of sanctuaries in which birds may nest and live safe from molestation is the most effective method of protecting birds. A sanctuary may be a nature reserve, where all wild life is encouraged, or be maintained for the benefit of certain species. Protection may be afforded by the State, a municipality, a society, or a private individual; in any case the reserve must be secure from poaching or collecting. National reserves, many State-supported, are maintained in the British Isles, Canada, Australia, New Zealand, Africa and other parts of the empire, in the United States and various European countries. Municipal parks all the world over are, as a rule, effective sanctuaries.

Guarded reserves have saved from extermination many species of economic or aesthetic importance; the plume-bearing herons and egrets in America, the kiwis in New Zealand, the spoonbill in Holland, and the Kentish plover in England are examples. Protection societies usually aim at preserving all birds on a reserve, but this policy has drawbacks; not only may unrestricted increase of predatory species decrease the birds they feed upon, but more adaptable birds, becoming competitors for food and nesting sites, often crowd out those in greater need of protection. Black-headed and herring-gulls are in some sanctuaries in Britain and Holland threatening the welfare of rarer birds, and in the Shetland reserves the great skua, nearly extinct before their foundation, is now a serious problem. Privately owned sanctuaries, some even game preserves, where discreet selection of species is the rule, have done much to protect and reinstate threatened birds.

The magpie, jay and other avian egg robbers often are too numerous in municipal parks and society reserves for the welfare of smaller passerine birds; but on private estates their depredations are checked. The re-establishment in East Anglia of the bittern as a nesting species is a triumph of private protection. In all parts of the world the preservation of undrained marshes, woodland, and untilled open country has justified the public and private expenditure and care bestowed upon them, by the increase of rare, formerly exploited birds.

(1925); E. M. Nicholson, *Birds in England* (1926); D. L. Sharp, "Sanctuary! Sanctuary!" (1926), for bird reserves in the United States; T. A. Coward, *Bird Life at Home and Abroad* (1927). (T. A. C.)

The United States.—The bird sanctuary movement in this country had its inception in public spirited efforts to protect in summer various small islands where sea-fowl gather to breed. Such a necessity was deemed to have arisen when the vast killing of gulls, terns and some other birds to supply the demands for feathers for the millinery market was raging 30 or 40 years ago. As rapidly as the various States were induced to enact the new Audubon Law, protecting non-game birds, guards were employed to prevent further raids on sea-bird colonies. The kind of guardianship, begun along the New England coast about 1900, by the National Association of Audubon Societies, was soon extended by this organization to include the rookeries of egrets, herons and ibises in the swamps of the South Atlantic and Gulf States.

In 1903, President Theodore Roosevelt, yielding to the urgings of the Audubon Association officials, began setting aside, by executive order, areas of Government lands known as "Federal Bird Reservations." He did this with the understanding that for a time at least the association should bear the expenses of guarding them. Other presidents have since followed this example and such reservations created by this method and administered by the U.S. Biological Survey now (1928) number 71, being distributed as follows: Alabama (1), Alaska (9), Arizona (1), Arkansas (1), California (3), Florida (11), Hawaii (1), Idaho (2), Louisiana (4), Michigan (2), Minnesota (1), Montana (4), Nebraska (1), Nevada (1), New Mexico (2), North Dakota (2), Oregon (6), Porto Rico (2), South Carolina (1), South Dakota (1), Utah (1), Washington (7), Wisconsin (2) and Wyoming (5). Many of these are very important gathering places of water-fowl. Malheur lake, a famous summering place for ducks, geese, grebes, terns and white pelicans in south-eastern Oregon, contains about 89,000 acres. Big lake, a popular winter resort for ducks in eastern Arkansas, covers 7,774 acres. Anaho island in Pyramid lake, Nev., contains the nesting places of the largest single colony of white pelicans in the United States. Other areas are only an acre or two in extent, and are inhabited by small numbers of brown pelicans, cormorants or terns.

The most adequately administrated reservation for wild fowl in the United States, the Paul J. Rainey Wild Life sanctuary, situated in Vermilion Parish, La., is owned and maintained by the National Association of Audubon Societies. Its 40 sq. m. of marshes are not only patrolled by guards throughout the year, but by constant supervision, the ponds, canals and levees are kept in good condition. New areas are being planted with vegetation enjoyed by ducks, and hundreds of bushels of grain are fed annually to the feathered hosts that assemble here. Many of the fowl, attracted by abundant food and the absence of all alarms, feed almost constantly within a few yards of the headquarters camp. In addition to 21 species of ducks, the blue and lesser snow geese pass the winter here in great numbers—flocks of 20,000 or more not infrequently being observed. One hundred and thirty-one species of birds have been identified on the Rainey sanctuary. The Audubon Association maintains 49 sanctuaries of varying degrees of importance. They are distributed as follows: Florida (6), Georgia (2), Louisiana (10), Maine (11), North Carolina (2), New Jersey (1), New York (2), South Carolina (3), Texas (10), Virginia (2).

There is also a different type of sanctuary—one designed especially for small birds. Usually the area selected is undeveloped woodland near a village, where birds are supplied with nesting boxes, feeding trays and places for drinking and bathing. Here people can come to study the habits and activities of the birds of the neighbourhood and acquire first-hand knowledge of the best methods of attracting them about the home. The sanctuary of the Meridan, New Hampshire Bird Club, established in 1911, was the first one of this kind to attract special notice. The type has become popular, and new ones are constantly being established. Among the better known and more adequately administered small-bird sanctuaries are "Birdcraft" at Fairfield, Conn., "Moose Hill" in Massachusetts, and the "Roosevelt Memorial," near the

grave of Theodore Roosevelt at Oyster Bay, N.Y. At these places special care is exercised to guard birds against the depredation of hunters and wild-life enemies. They are in charge of naturalists who explain to thousands of visitors the meaning and usefulness of a bird sanctuary, and how to care for wild birds about one's home.

Of recent years many States have been establishing "Wild Life Refuges." With few exceptions these are forest areas, wherein all hunting of game birds and animals is prohibited. They are designed chiefly as safe breeding and feeding places for game which may so increase under protection, that they will eventually spread to the surrounding country and provide better hunting territory for sportsmen. To a considerable extent they are bird sanctuaries. There are within the United States 19 national parks, and 32 national monuments, on all of which injury to bird life is prohibited. City and State parks likewise are usually immune from hunting, for the restrictions against shooting or trapping are carefully enforced in many of them. In some cities the park boards have caused to be erected many bird-nesting boxes and drinking fountains. (T. G. P.)

BIRD'S-EYE, a name applied to various small bright flowers, especially those which have a small spot or "eye" in the centre. The primula is thus spoken of, on account of its yellow centre, also the adonis, or "pheasant's eye," and the blue veronica, or germander speedwell. The word is also applied to a sort of tobacco, in which the stalks (of a mottled colour) are cut up together with the leaves. From a similar sense comes the phrase "bird's-eye maple," a speckled variety of maple-wood, or the "bird's-eye handkerchief" mentioned in Thackeray's novels.

BIRD-NESTING, a general term for the collection of birds' eggs for preservation, with or without the nests themselves. The nests and eggs of wild birds are protected by local laws almost everywhere in both Great Britain and the United States. By law they may be taken for scientific purposes only, by special licence. In order not to interfere seriously with breeding it is customary to take but one egg from a nest, and, if the nest itself be taken, to wait until the young birds have left it. Every egg, unless "hard-set," should be blown as soon as removed from the nest. This is done by opening a small hole in its side by means of a drill with a conical head, manufactured for the purpose, a minute hole for the insertion of the drill-head having first been made in the shell with a needle, which is then used to stir up the contents, so that they shall flow easily. A blow-pipe with a curved mouth is then inserted, the egg is held hole downwards, and the contents blown out. The old-fashioned method of making two holes in the egg is thus superseded. Should the egg be "hard-set" a somewhat larger hole is made, and its edges reinforced with layers of paper pasted round them. Minute forceps are then introduced and the embryo cut into pieces small enough to pass through the hole. The inside of the egg is then rinsed out with clean water, and also before being placed in the cabinet, with a solution of corrosive sublimate, which prevents decay and consequent discolouration of the inner membrane. Finally the egg is placed with the hole downwards upon a sheet of white blotting-paper to dry. The authentication of the eggs is the most important duty of an egg-collector, next to identifying the specimens.

Many ornithologists hold that bird-nesting should be discouraged as a serious menace to all the rarer birds.

BIRDS OF PARADISE form the family *Paradisæidae*. There are many genera, all confined to the Papuan region; their nearest allies are the crows. In brilliance and beauty of plumage the males are unequalled, but the females are duller. The largest, the great bird of paradise (*Paradisæa apoda*), is confined to the Aru Islands. The adult males have a yellow head, green throat and golden plumes, the latter, as in most *Paradisæidae*, springing from beneath the wings. During the breeding season, they display

these before the females, many congregating on special trees for this purpose (for an account of which, see Wallace's *Malay Archipelago*). They are then easily approached and many are shot by the natives. The lesser bird of paradise (*P. minor*) is smaller and somewhat less brilliantly coloured. It is found throughout New Guinea and the neighbouring islands. The king bird of paradise (*Cicchnus regius*) has the two middle tail feathers coiled into a spiral and webbed only at the ends. The twelve-wired

(*Seleniclerus alba*) is so called from the fact that twelve of its plumes are transformed into long, wire-like bristles. There are numerous species, many known only from single skins. Birds of paradise are omnivorous and, possibly, polygamous. (See RIFFELMAN-BIRD and plate illustration under SEXUAL SELECTION.)

BIRDWOOD, SIR GEORGE CHRISTOPHER MOLESWORTH (1832–1917),

Anglo-Indian official and writer, son of Gen. Christopher Birdwood, was born in India on Dec. 8, 1832, and died at Ealing, London, on June 28, 1917. After taking his medical degree at Edinburgh, he joined the Bombay Medical Service in 1854, and served in the Persian War of 1856–57. During 14 years' residence in Bombay he filled many important positions and rendered very great services to the community, which were recognized by his appointment as sheriff of that city in 1864. Ill health, however, compelled him to return to England in 1868, and in 1871 he entered the India Office, where he served for the next 30 years. During this period he published an important book on the industrial arts of India, edited the ancient records of the India Office, and first letter-book of the East India Company; he also made arrangements for the Indian exhibits at the principal international exhibitions. He kept up a close connection with India through the many distinguished Indians visiting London, and he published several works on Indian botany, on which he was an acknowledged authority, and on Indian folk-lore. In politics he was a Conservative, and was one of the initiators of Primrose day. Birdwood was created K.C.I.E. in 1887.

BIRDWOOD, SIR WILLIAM RIDDELL (1865–), British field-marshal, was born Sept. 13, 1865. He joined the 12th Lancers in 1885 and was in the following year transferred to the Indian Staff Corps, joining the cavalry. After service in several frontier expeditions, and in the South African War (1890–1902), he was closely associated for several years with Lord Kitchener in India, acting as his military secretary. Lord Kitchener, in Dec. 1914, selected him for the command of the Australasian forces which were being assembled in Egypt, and in the following April he commanded this army corps in the memorable landing at Anzac. He was in charge of the troops clinging to this patch of the Gallipoli Peninsula until August, and his personality won the confidence and regard of these Australasian troops in a unique degree. Birdwood carried out the masterly withdrawal of the Dardanelles forces from their dangerous positions in the following December and January. After a short period in Egypt he took his Australasian troops to the western front, where they played an important part in the last phases of the British advance in the autumn. For his services he was made a baronet, besides receiving a grant of £10,000. He paid a visit to the Antipodes a year after the World War. In 1920 he took up command of the northern army in India, and in 1925 was promoted field-marshal and appointed commander-in-chief in India.

BIREN (or Bühren), **ERNST JOHANN** (1690–1772), duke of Courland, was the grandson of a groom in the service of Duke Jacob III. of Courland, who bestowed upon him a small estate, which Biren's father inherited. He received what little education he had at the academy of Königsberg, from which he was expelled for riotous conduct. In 1714 he set out to seek his fortune in Russia, and unsuccessfully solicited a place at the

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

MARQUIS RAGGI'S BIRD OF PARADISE (PARADISEA RAGGIANA, SCLATER), ONE OF THE LESS KNOWN MEMBERS OF THE BRILLIANT PLUMAGED FAMILY

shabby court of the princess Sophie Charlotte, the consort of the tsarevich Alexius. Returning to Mitau, he succeeded in gaining a footing at the court of Anne, duchess of Courland, through one of his sisters, who was the mistress of the ruling minister, Peter Bestuzhev, the lover of the duchess. Biren supplanted him in the favour of Anne, and from henceforth to the end of her life his influence over her was paramount. On her elevation to the Russian throne in 1740 Biren, who had in the meantime married Frhulein von Treiden, came to Moscow, and honours and riches

were heaped upon him. At the coronation (May 19) he was made grand-chamberlain, a count of the empire, on which occasion he is said to have adopted the arms of the French ducal house of Biron, and was presented with an estate at Wenden with 50,000 crowns a year. He soon made himself cordially detested by Russians of every class. He was mean, treacherous, rapacious, suspicious and horribly vindictive. Half the bribes intended for the Russian court passed through his coffers. On the extinction of the line of Kettler, the estates of Courland, in June 1737, elected him their reigning duke. He was almost as much loathed in Courland as in Russia; but large sums of money, smuggled into Courland in the shape of bills payable in Amsterdam to bearer, speedily convinced the electors. On her death-bed Anne appointed him regent during the minority of the infant emperor, Ivan VI.

Biren's regency lasted exactly three weeks. At midnight on Nov. 19, 1740, he was seized in his bedroom by his ancient rival, Field Marshal Münnich. The commission appointed to try his case condemned him (April 11, 1741) to death by quartering, but this sentence was commuted to banishment for life at Pelym in Siberia. All Biren's vast property was confiscated, including his diamonds, worth £600,000. The ex-regent re-emerged for a brief moment in 1762, when the philo-German Peter III. summoned him to court. Catherine II. re-established him (1763) in his duchy, which he bequeathed to his son Peter. He died at Mitau, his capital, on Dec. 28, 1772.

See Robert Nisbet Bain, *The Pupils of Peter the Great* (1897); Christoph Hermann von Manstein, *Memoirs* (Eng. ed., 1856); Claudius Rondeau, *Diplomatic Dispatches from Russia* (St. Petersburg, 1889–92).

BIRETTA, a cap worn by the Catholic clergy. It is square and stiff, being made of a framework of cardboard covered with cloth or silk; on the top, along the sutures of the stuff, are three or four raised, board-like, arched ridges, at the junction of which in the centre is a knob or tassel. Its colour varies with the rank of the wearer, that of the pope being white, of the cardinals red, of bishops purple, and of the lower clergy black. It is not in the strictest sense a liturgical head-dress, its use not being confined to liturgical functions.

Though the form of the biretta, devised in the 17th century, is peculiar to the Roman Church, it is but a variant of the original *biretum*, "barret cap," which developed in various countries into head-coverings of different shapes and significance. When the word *biretum* first appeared in the 13th century, it practically meant no more than "cap," and was used as a synonym of *pileus*, the skull-cap used by the clergy, as a protection against cold. With the extension of its use, the custom grew up (c. 1300) of investing clerks with the *biretum* as the symbol of the transfer of a benefice, a custom which survives, in Roman Catholic countries, in the delivery of the red biretta (*zucchetto*) by the head of the State to newly created cardinals, who afterwards go to Rome to receive the red hat.

This use of the *biretum* as a symbol of office or dignity was not confined to the clergy. It was worn by all persons of standing, e.g., barons, judges, and doctors and masters of the universities. The "cap of maintenance" or "cap of estate," still borne before the British sovereign on State occasions, is a barret-cap of the type of the 14th and 15th centuries; it is of crimson velvet, turned up with ermine. By the 16th century the barret-cap in various forms had become the common head-gear of all people of substance. By the 17th century it had given place in ordinary civil life to the brimmed hat; but in various shapes it still survives as official head-gear in many European countries: the *barett*, worn by the Lutheran clergy, by German lawyers, and by the deans and rectors of the universities, the *barrette* of

French judges and barristers, the "black cap" of the English judge, and the "college cap" familiar in English and American universities, and vulgarly known as the "mortar-board."

The ecclesiastical developments of the *biretum* are not without interest and significance. Originally this had been a round cap, slightly bulging out at the top, and ornamented with a knob. By the 16th century, both in England and on the continent, a tendency had begun to emphasize the ridges of the sutures and thus produce a square shape. Henceforth the evolution followed different lines. In England, in the 17th century, the square flat top began to be enlarged, forming a rim of thick stuff projecting beyond the close-fitting cap. This was the "square cap" denounced by the Puritans as a symbol of high church Erastianism. With the triumph of high church principles at the Restoration, a loyal clergy desired to emphasize this squareness, and the consequent exaggeration of the square top of the cap necessitated a further stiffening. In the 18th century, accordingly, the top began to be made of a board of wood or card covered with cloth, the close-fitting cap proper retired farther from the edges, the knob developed into a tassel, and the evolution of the modern "college cap" was complete.

On the continent, meanwhile, in the Roman Catholic Church, the *biretum* had also developed into its present form, and by a very similar process. At the beginning of the 17th century card-board was introduced to stiffen the sides of the cap and emphasize the squareness, and the form of the biretta, as described above, became fixed.

The use of the Roman biretta has been introduced by a certain number of the clergy into the Anglican Church. There is no historical justification for this; for though both college cap and biretta are developed from the same "square cap," the biretta in its actual shape is strictly associated with the post-Reformation Roman Church, and its actual ceremonial use is of late growth.

BIRGER (d. 1266), Swedish statesman, nephew of Birger Brosa, and the most famous member of the ancient noble family of the Folkungæätten, was created jarl of Bjälbo by King Erik Eriksson in 1248 and married the king's sister. On Erik's death (1250) Birger's son Valdemar was elected king while his father acted as regent. During the sixteen years of his sway Sweden advanced greatly in fame and prosperity. In 1240 he led an expedition to Finland, built the fortress of Tavastehus, and thus laid the foundations of Sweden's oversea empire. He also built Stockholm and enriched it by making it the chief mart for the trade of Lübeck, with which city he concluded a commercial treaty. In his old age he married the daughter of King Abel. There is a fine statue of the great jarl in the Riddarholm church at Stockholm, erected by Fogelberg at the expense of the Stockholm magistracy in 1884.

See *Sveriges Historia*, vol. i. (1879-83).

BIRIBI or **CAVAGNOLE**, a French game of chance, prohibited by law since 1837. In the French army "to be sent to Biribi" is a cant term for being sent to the disciplinary battalion in Algeria.

BIRIJIK, a town on the Euphrates in 37° N, 38° E, about 15m. above the railway bridge at Jerablus; it is on the telegraph line and the caravan route to Aleppo, Diarbekr, etc., and has an estimated population (1928) of 19,000, among whom are Armenians, Arabs, Jews, Kurds and Turks.

The town lies in the centre of a district engaged chiefly in the cultivation of barley and wheat, and has a certain amount of trade—mostly locally, on the Euphrates—in agricultural products, butter, grapes and olive-oil. It is also a sheep-market, and has a small industry in boat-building.

BIRJAND, a town of Persia in the Kain district of the province of Khurasan, 35° 53' N. and 59° 10' E., built on low hills in a barren and treeless valley, on a plateau 4,440ft. in elevation, and divided by the broad bed of a river. The population is variously estimated at 14,000-18,000. It is a busy commercial town with good caravanserais and a college. It is situated 328m. south

of Meshed on the main road to railhead at Duzdab, which, in recent years, has been made passable for motor cars. The surrounding district has long been famed for its carpets, which almost all come from Durruksh about 50m. to the north-east. Saffron is very extensively cultivated round Kain, while the barberry grows to perfection at Birjand. Wheat and barley, sufficient for local needs, are grown in normally good years. The water-supply in the surrounding country is scanty. The inhabitants include a strong Sunni element; the Afghan community is also strong, and in Birjand itself and among the nomads of the region there is a large Arab-speaking element. There is a British vice-consulate and a telegraph office at Birjand, having direct communication with Meshed and Duzdab.

See P. M. Sykes, *10,000 Miles in Persia* (1902).

BIRKBECK, GEORGE (1776-1841), English physician and philanthropist, was born at Settle in Yorkshire on Jan. 10, 1776. In 1799, after graduating as doctor of medicine, he was appointed to the chair of natural philosophy at the Andersonian institution of Glasgow. In the following year he delivered a free course of scientific lectures for working men. He removed to London in 1805, and there, in 1823, he helped to found the Mechanics' institute, the name of which was afterwards changed to Birkbeck institution or college, in honour of its founder. He was appointed director of the institute, which he had originally endowed with the sum of £3,700, and held the office till his death on Dec. 1, 1841. The scope of the institution was gradually extended, and an enlargement of the buildings was carried out in 1883-85. The college became a constituent college of London university in 1920.

See C. Delisle Burns, *A Short History of Birkbeck College* (1924).

BIRKENFELD, a market town in West Germany, 25m. E S E of Trier, capital and seat of government of the province of Birkenfeld, in the republic of Oldenburg. Pop. 2,618. Above the town lie the ruins of a castle (14th century), once the residence of the counts palatine of Zweibrücken. The province (formerly principality) of Birkenfeld is hilly and well forested. Pop. (1925) 55,649. It is entirely an *enclave* in Prussian territory. Ironstone and roofing slates are quarried and agate-polishing is practised at Idar.

BIRKENHEAD, FREDERICK EDWIN SMITH, 1ST EARL OF (1872-), British politician and lawyer, was born at Birkenhead, July 12, 1872. Educated at Birkenhead grammar school and Wadham college, Oxford, where he was a scholar, he took a first-class degree and in 1894 was president of the Union.

Choosing the law as a career, Smith was called to the bar at Gray's Inn in 1899, and later attached himself to the local bar at Liverpool, where his natural abilities swiftly gained him a considerable practice. Following his Oxford tradition as a Conservative, he was adopted as candidate for the Walton division of Liverpool and made a speech at a public meeting which greatly impressed Joseph Chamberlain. Elected M.P. for Walton in 1906, he held that seat until raised to the lord chancellorship in 1919. He signalled his entry into the House of Commons by delivering, from the broken ranks of the Opposition, a maiden speech of brilliant mockery which made his reputation. A rapidly growing practice at the London bar, where he took silk in 1908, hindered him from pursuing the regular routine of parliamentary opposition.

His forensic style differed from his method of public oratory. He inclined to be quiet, dispassionate and deadly in cross-examination. A tremendous worker at the bar, he undertook tasks which would have overwhelmed most men in combining law and politics. After the retirement of Chamberlain popular Conservatism found in him its most telling exponent, and in the art of the platform even Lloyd George had to reckon with him.

Smith took a prominent part in the struggle over the Parliament bill. He moved its rejection on the third reading, May 1911, and threw in his lot with the die-hards, who desired the peers to reject the measure. His growing position was recognised by a privy councillorship in 1911 and he became an accepted member of the Conservative "shadow" cabinet. The Irish question was now becoming acute and Smith was Sir Edward Carson's principal lieutenant in the resistance organised in Ulster.

The World War closed the original Irish controversy. Smith accepted the task of controlling the Press Bureau, went to France as eye-witness with the Indian corps, and did valuable work in the administration of army law. He was recalled from France to become solicitor-general in the first Coalition of 1915, and succeeded Sir Edward Carson as attorney-general in November of that year. In this year he was knighted.

When Lloyd George reconstructed his Ministry after the election of 1918 the attorney-general was offered the lord chancellorship, and was raised to the peerage as Viscount Birkenhead in 1919. The appointment, though quite in the normal order of promotion, was subjected to considerable criticism, partly owing to the new chancellor's comparative youth, but chiefly to his vehement partisanship in earlier years. His chief legislative achievement during his term of office was the Law of Property Act of 1922. This reform, long overdue but perpetually held up by the inertia of the various legal authorities and interests, revolutionised the whole system of holding landed property. Among Lord Birkenhead's most notable judgments were (1) Director of Public Prosecutions *v.* Board, dealing with drunkenness as an excuse for crime; (2) Wakeford *v.* The Bishop of London; (3) the Rhondda Peerage case before the Committee of Privileges, laying down that women could not sit in the Upper House by right of peerage; (4) Admiralty *v.* s.s. "Volute"—a judgment on the law of negligence in collision cases. Of this fourth deliverance Lord Finlay said "I regard the judgment to which I have just listened as a great and permanent contribution to the law on the subject of contributory negligence, and to the science of jurisprudence."

The fall of the Coalition Government of 1922 was brought about by the desire of the rank and file of the Conservative party to regain its independence. Lord Birkenhead and some other Conservative ministers opposed this movement in vain at the Carlton Club meeting. As a consequence he was not included either in the administration of Mr. Bonar Law or in that of Mr. Baldwin, and he assumed an attitude of marked independence. On vacating the lord chancellorship he had been made an earl. Mr. Baldwin prudently healed the breach in the Conservative ranks on assuming office again in 1924, and Lord Birkenhead became secretary of state for India. He resigned from the India office and left the Cabinet in Oct. 1928 in order to devote himself to a commercial career.

Lord Birkenhead, as an Oxford scholar, has a natural taste for letters, and his libraries are filled with carefully selected volumes. His work on international law has gone through several editions. The essay on Lord Salisbury, originally published in *The Times*, is his best historical work, and the short sketches of his young friends who died in the War reveal the human side which he always shows to youth. He married in 1901 Margaret Eleanor, daughter of the Rev. Henry Furneaux of Oxford, the editor of *Tacitus*. They have one son (Viscount Furneaux) and two daughters, the Ladies Eleanor and Pamela Smith. (M. W.)

BIRKENHEAD, a municipal, county and parliamentary borough and seaport of Cheshire, England, on the river Mersey, opposite to Liverpool, and 195 m. N.W. of London. Pop. (est. 1927) 161,254; area 6,016 ac; under a mayor, 15 aldermen and 45 councillors. Rateable value £983,606. A Benedictine monastery was founded here (c. 1150) by Hamon de Mascsey and drew revenues from tolls levied at the Mersey Ferry. In 1818 Birkenhead was a hamlet of 50 inhabitants and its development is largely due to the establishment of shipbuilding yards by William Laird, a pioneer of iron vessels, in 1824. Telford, Stevenson and other engineers favouring the conversion into a basin of Wallasey pool, a creek of the Mersey, parliamentary powers were obtained in 1843 and the first docks were carried out by James Rendel in less than five years, and opened in 1847. In 1858 they passed under the control of the Mersey Docks and Harbour Board. Subsequent large additions have brought the total quayage to ten miles. The town was built on the rectangular block plan; and the first street tramway in Europe was started here in 1860. The town was created a parliamentary borough returning one member in 1861, but since 1918 it has returned two members. The charter of municipal

incorporation was granted in 1877 and a large extension of boundaries was secured in 1927.

Besides sharing in the general trade of the Merseyside port Birkenhead has developed an individual trade in the export of Midland manufactures and in trade with the East. The two great "floats" or main basins of the dock system have attracted a gigantic milling industry which makes Birkenhead the largest milling centre in Europe. A vast cattle and meat trade is carried on at lairages and abattoirs on the river front. Cammell Laird and Company, the successors of W. Laird, conduct great shipbuilding yards here. Port Sunlight lies near the southern boundary.

Birkenhead is the northern terminus of the G.W. Railway. From Chester to Birkenhead the line is shared with the L.M. and S. railway, and the town is thus connected with the main lines of the two largest railway systems. Most of the other systems have depots at the docks. The corporation run a steam ferry to Liverpool for vehicles, goods and passengers (separate steamers for the latter) from Woodside near the dock entrances and a second (passenger) ferry from Rock Ferry, farther south. Passengers and lighter goods traffic are also catered for by the Mersey tunnel (electric) railway, and in a year or two the traffic tunnel now being constructed by the two corporations will effect a further link between Birkenhead and Liverpool. The municipal undertakings include gas, water supply, electricity, tramways and omnibuses, steam ferry, public market and public bath.

Public buildings include the town hall, the New Art gallery, Birkenhead park entrance arch, St. Aidans Theological college, the central library and the General hospital.

BIRMINGHAM, city, county and parliamentary borough, England, in the north-west of Warwickshire, but with suburbs extending into Staffordshire on the north and west and into Worcestershire on the south, 113 m. N.W. of London by rail. Pop. (1921) 919,444.

Birmingham is built upon the new red sandstone, and situated in the valleys of the Rea and other small feeders of the River Tame, near their sources, and upon the rising ground between these valleys. The site, therefore, varies from 200 to 600 ft. above the sea-level, steadily rising towards the north and west, while the well-marked line of the Lickey hills skirts the site on the south-west, extending thence south-eastward. From the high ground to the south-east Birmingham thus presents the appearance of a vast semicircular amphitheatre. Its general situation near the centre of England makes it a great railway focus. The main lines are controlled by the L.M.S.R. and G.W.R. The plan of the town, as dictated by the site, is irregular. In the centre are several fine thoroughfares, containing nearly all the most important buildings. New street, Corporation street and Colmore row are the chief of these. At the western end of New street is a fine group of buildings, including the council house and art gallery, the town hall and post office. Corporation street was the outcome of a great "Improvement scheme" initiated in 1875 with the object of clearing away insanitary property and of constructing a main thoroughfare from the centre to the north-eastern outlet, starting from New street, near the railway station, to Bull street, and thence continuing to the Aston road. The scheme received parliamentary sanction in 1876, and was finished in 1882. This led to an almost total extinction of dwellings in the centre of the town. Edgbaston and Harborne lie south-west of the centre of the city, and form a residential district. To the south of Edgbaston, however, are the growing manufacturing districts of Selly Oak and Bournville, and south of these, Northfield and Kings Norton, in Worcestershire. The districts to the east of central Birmingham are Balsall Heath, Sparkbrook, Small Heath and Saltley. On the south-east is the residential suburb of Moseley, and on the east that of Yardley. On the east side the transition from town to country is clearly marked. This, however, is not the case on the west side, where the borough of Smethwick adjoins Birmingham, and the roads through West Bromwich and towards Oldbury and Dudley have the character of continuous streets. On this side are Soho and Handsworth. To the north lies Aston Manor, with Perry Bar beyond. To the north-east a populous district extends towards the town of Sutton Coldfield. Besides these and the Edgbaston grounds the

chief parks are Summersfield park, towards Smethwick; Soho park; Victoria park, Handsworth; Adderley park, towards Saltley; and Victoria park, Small Heath. There is a race-course at Castle Bromwich, three m. E. of the town. Birmingham has increased greatly since 1911, when Aston Manor, Erdington and Handsworth, almost the whole of Norton and Northfield and the rural district of Yardley were added to the city. The influx of munition workers in 1914-18 greatly increased the population of the city. Since 1918 a housing policy has been formulated and town planning schemes for the various suburbs approved. Parks and open spaces have been acquired including Perry reservoir (1919), Selly park (1910-14), Barr Beacon (1919), Pye Hayes park (1920), Swanshurst park (1917-23), Kings Norton site (1920); Rose Hill Redual (1920). Ambitious schemes for road widening and improvement of traffic conditions are in hand, especially the construction of an arterial road (80 ft. wide) passing over New street station as a viaduct.

History—Although there are local evidences of early man, the first record we have of the site is in Domesday where an under-tenant of William Fitz Ansculf is recorded as having four "hides" there. Other Domesday evidence leads us to the conclusion that at the end of the 11th century Birmingham was far from being the chief place in the district. By the end of the 13th century a considerable market town had grown at the focus of roads in the Bull Ring. Market charters had been granted in 1166, 1189, 1249 and 1295. In the 16th century it was visited by both Leland and Camden. The first tells us that "there be many smithes in the towne that use to make knives and all maner of cuttyng tooles, and many lorimars that make byts, and a greate many naylors, so that a great parte of the towne is mayntayned by smithes," and he adds further that these smiths obtained the "yren out of Staffordshire and Warwickshire, and their see coale out of Staffordshire." A town with an ever growing middle-class artisan population on one of the great roads between Oxford and the north and west found many opportunities for interrupting communications between the Royalist commanders. A skirmish in which Prince Rupert was involved seems to have been exaggerated by contemporary accounts on both sides. In 1665 Birmingham suffered heavy losses by the Plague. The Revolution of 1688 was a signal for the outbreak of Protestant feeling and a Roman Catholic church built under the patronage of James II. in a place now known as Masshouse lane was destroyed. By the Acts of Uniformity and the Five Mile act non-conforming ministers were forbidden to dwell within a corporate town, but Birmingham though wealthy and populous had not that distinction; its government was that of a manor and hence it became a great home of dissent. Quakers, Unitarians and Jews and the persecuted of every sect found in it a sanctuary. The leader of the city in intellectual and social movements during the latter half of the 18th century was Dr. Priestley, and around him gathered such men as Baskerville, Hutton, Withering and others. The unfortunate events that followed a Bastille celebration dinner on July 14, 1791, caused this group to disperse. In the dismal period from 1817 to 1819 when the manufacturing districts were heavily distressed and were disturbed by riots, Birmingham remained quiet. Even when some of the inhabitants were tried and punished for demanding parliamentary representation, and for electing Sir Charles Wolseley as their delegate, there was no demonstration of violence. In 1831-32 the Political Union was formed, under the leadership of Thomas Attwood, to promote the passing of the Reform bill. Vast meetings were held on Newhall Hill. Ultimately the Political Union succeeded in its object, and Birmingham helped to secure for the nation the enfranchisement of the middle-classes and other political reforms. The occurrence of riots in 1839, during the Chartist agitation, showed the social unrest that accompanied the rapid development of the industrial town. The interest and enterprise of the Chamberlain family during the latter half of the 19th century did much to improve the city (see later).

Birmingham is not rich in ecclesiastical architecture. It became a bishopric under the Bishoprics of Southwark and Birmingham act 1904. Before 1821 it was in the diocese of Lichfield. There were formerly a religious house, the priory of St. Thomas the

Apostle, and a Gild of the Holy Cross, an association partly religious and partly charitable, having a chantry in the parish church. The possessions of the priory went to the crown at the dissolution, and the building was destroyed before the close of the 16th century. Until 1715 there was but one parish church, St. Martin's, erected about the middle of the 13th century but entirely rebuilt in 1873. St. Philip's, designed by Archer, a pupil of Wren, was the next church erected. It was consecrated in 1715, enlarged in 1884, and became the pro-cathedral on the foundation of the diocese. It contains a rich series of stained-glass windows by Burne-Jones. Then followed St. Bartholomew's in 1749, St. Mary's in 1774, St. Paul's in 1779, St. James's, Ashted, in 1791, and others. The traditional reputation for Nonconformity is maintained by the town. The Unitarians, the oldest body established here, have among their chapels, the Old Meeting, on the site of one of the original Unitarian chapels. Another chapel, the New Meeting, in Moor street, is memorable as having been the place of Dr. Joseph Priestley's ministerial labours from 1780 onwards. In 1862 the Unitarians removed from this place to the church of the Messiah in Broad street. The first meeting-house of the Society of Friends dates from about 1600. Among Independent chapels, that of Carr's lane has had John Angell James and Robert William Dale as ministers. The Baptists first erected a chapel in Cannon street in 1738. John Wesley himself in 1745 established the Wesleyan Methodists in Birmingham. The Presbyterians have also places of worship, and the Jews have a synagogue. From the revolution of 1688 until 1789 the Roman Catholics had no place of worship here; but Birmingham is now a Roman Catholic bishopric. Cardinal Newman was superior of the Oratory of St. Philip Neri from its foundation in 1851.

Education.—The oldest educational institution is the grammar school of King Edward VI., founded in 1552 with a grant of the lands of the Gild of the Holy Cross. The principal school included in the foundation is the boys' high school; others, with a girls' high school, are on the endowment. Queen's college, founded in 1828 as a school of medicine, subsequently embraced other subjects, though in 1882 only the medical and theological departments were maintained. In 1882 a large part of the scientific teaching, hitherto done by special professors in Queen's college, was taken over by Mason college, and in 1892 the whole medical department was removed to the same institution under an order from the court of chancery. In 1898 a public meeting carried a resolution in favour of creating a university, in which Mason college was merged. Since 1922 departments of Legal Studies, Oil Engineering and Town Planning have been instituted; new buildings have been provided for the biological departments; the university has become associated with the Coal Owners' Mining Research Laboratory and the joint Board for Research in Mental Diseases; the Treasury grant has been increased, and, in response to appeals, large sums have been raised and scholarships, research funds, etc., founded. The faculty of commerce constitutes a distinctive feature in the scheme of the university, the object being to bring its teaching into close touch with the industrial life of the city. A site at Edgbaston was given by Lord Calthorpe and a large building scheme is being worked out. The Municipal School of Art was formed by the transference to the corporation in 1885 of the then existing school of art and the Society of Arts, and by the erection of the building in Margaret street. The Midland institute, the building of which was founded in 1855 and enlarged subsequently, includes a general literary and an industrial department. The Municipal Technical school was established in 1893 in the building of the Midland institute, and in 1895 was housed in Suffolk street, whither the whole of the scientific teaching of the institute was transferred.

The principal libraries are the Birmingham library, founded in 1798 by Dr. Priestley, the Central free library, and other free libraries in different parts of the city, each with a lending department and a reading room. The general Hospital, the foundation of Dr. Ash, was opened in 1779 and rebuilt in 1897. There are also almshouses for aged persons, kept up by old trusts, chiefly Lench's Trust and James' Charities. Among a series of public monuments are those of Priestley, Attwood, Watt, Peel, Rowland Hill and Nelson. The wide importance of Birmingham as a centre of manu-

factures began towards the close of the 17th century, one great factor being the absolute freedom of the town, with no guilds, companies or restrictions of any kind; besides which the easy access to cheap coal and iron indirectly helped the development. It is remarkable that two important trades, now located elsewhere, were first established here. Steel was made in Birmingham until 1797, and cotton-spinning was begun here by John Wyatt, Lewis Paul and Thomas Warren as early as 1730; but the speculation was abandoned before the end of the century. The great staple of Birmingham is metal-working in all its various forms. The chief variety is the brass-working trade. Iron-working, though largely carried on, is a much less important trade, works of this kind being chiefly established in the Staffordshire district. Jewellery, gold, silver and gilt come next to brass. Then follow "small arms" of all kinds. Until 1906 a Royal Small Arms factory was maintained by the government at Sparkbrook, but it was then transferred to the Birmingham Small Arms Co., which had already extensive works in the district. Buttons, hooks and eyes, pins and other articles used for dress, constitute a large class of manufactures. Glass, especially table glass is a renowned staple of the town. Screws, nails, etc. are made in enormous quantities; indeed, Birmingham has a monopoly of the English screw trade. Steel pens are also a speciality, the name best known in this connection being that of Sir Josiah Mason. Electro-plating, first established in 1841 by the firm of Elkington, is one of the leading trades. Among other branches of manufacture are wire-drawing, metal rolling, railway-carriage building (a large and important industry), the manufacture of cutting implements and tools of all kinds, die-sinking, papier-mâché making and a variety of others. In 1897 there was a sudden development of cycle manufacturing, followed in 1899 by an almost equally sudden collapse, but this industry is maintained and accompanied by the manufacture of motor-cars, tyres and accessories, for which Birmingham is one of the principal centres in Great Britain. Confectionery and printing on a large scale are also important. The output of munitions during the War (1914-18) was enormous and many of the large buildings erected during this period facilitated the development of local industries. Fort Dunlop is a new suburb occupied by the makers of rubber goods.

Administration.—The government of the town resided originally in the high and low bailiffs, both officers chosen at the court of the lord of the manor, and acting as his deputies. A charter was granted by the crown in 1838, vesting the general government in a mayor, 16 aldermen and 47 councillors. The powers of this body, were, however, unusually restricted, and it was not until 1851 that an act of parliament was obtained, abolishing all governing authorities excepting the town council. Another local act was obtained in 1862, and in 1883 these various acts were combined into the Birmingham Corporation Consolidation act. In 1889 Birmingham was created a city. The title of lord mayor was conferred on the chief magistrate in 1897. Under the Greater Birmingham Scheme of 1911 the city council consists of 30 aldermen and 90 councillors. The gas, electricity and water supplies are in the city council's hands. The main source of the water supply is the Elan valley (*q.v.*), Radnorshire, where extensive waterworks were completed in 1905. Justice was administered from 1838 to 1884 by a court of quarter sessions. In 1884 Birmingham was made an assize district of Warwickshire. The town was enfranchised in 1832 when two representatives were elected. In 1867 three members were assigned and in 1885 the number was increased to seven. Since 1918, 12 members have been returned to parliament. The area of the city of the Greater Birmingham Scheme of 1911 is 43,537 acres or about 68 square miles.

See W. Hutton, *History of Birmingham* (2nd ed., 1783); the Birmingham Archaeological Society's *Transactions*; and the British Association *Handbook* (1913).

BIRMINGHAM, the largest city of Alabama, U.S.A., in the north-central part of the State. It is on Federal highways 11, 31, and 78; and is served by the Atlanta, Birmingham and Coast, the Central of Georgia, the Frisco, the Illinois Central, the Louisville and Nashville, the Mobile and Ohio, the Seaboard Air Line, and the Southern railways, and by three additional local freight-

carriers, including the railway of the government-owned Warrior River Terminal Company, connecting (17m. from the switching limits of the city) with its terminal at Birminghamport, on the Locust Fork of the Warrior river, from which there is a navigable water-route to Mobile. It is the county-seat of Jefferson county, and a port of entry in the Mobile customs district. The population was 178,806 in 1920, of whom 70,230 were negroes, and 6,084 foreign-born white, and was estimated locally at 260,000 in 1927. The metropolitan area, including Bessemer (*q.v.*), Fairfield (*q.v.*) and other suburban communities, had a population in 1927 of about 360,000.

Birmingham is the leading industrial city of the South. It has been built entirely since 1870. The city proper lies in a long narrow valley (Jones valley), at an altitude varying from 700 to 1,045ft., and is protected by mountains to the south-east and north-west. Its residential environs spread over the mountain slopes and into the valleys beyond. The main streets are wide (80-100ft.) and most of the buildings are of modern construction. The hotels have over 3,500 guest rooms. Building permits issued during 1920-26 represented values amounting to \$95,000,000. The assessed valuation of property in 1927 was \$209,500,000.

The industrial development of the city is based on immense mineral deposits: coal, including good coking varieties; limestone and dolomite, used in fluxing steel; iron, approximating 1,700,000,000 tons of red ore and 27,000,000 tons of brown ore; besides graphite, marble, barytes, bauxite, pyrite, quartz, mill-stone, cement-rock, clays, sand and gravel, and many others in smaller amounts. All the materials needed for making steel are found here in close proximity. Electric energy is supplied from hydro-electric and steam-electric plants with an installed capacity of 708,700h p., on the Coosa and the Tallapoosa rivers, at Muscle Shoals, and at several other points. Pig iron and steel have always been the leading products; but other industries have developed until 2,000 different commodities, ranging (alphabetically) from acetic acid to zinc sulphate, are produced by the 700 mills, mines, and factories in the Birmingham district, and their annual output is valued at \$650,000,000. The district produced in 1926 about 22,000,000 tons of coal; 4,228,947 tons of coke, most of it in by-product ovens yielding vast quantities of coal-tar and supplying the city's mains with gas; 2,933,796 tons of pig-iron; 1,600,000 tons of steel. Other important products are cast-iron and clay-pipe; wire, nails, steel cars, car-wheels, rails and stoves; cotton gins and machinery for sugar-mills, coal-mines, and for washing coal; brick, cement, lumber and lumber products, cotton-seed oil and meal and fibre, corn-meal, meat, cotton goods, rubber tubes and tyres, chemicals, and explosives.

Birmingham is an important market for soft woods, especially yellow pine, of which it ships 50,000 cars annually. It is the shopping centre for a population of about a million. Post-office receipts in 1926 were \$1,626,599. Debts to individual banking accounts amounted to \$1,603,599,000.

The city operates under a commission form of government, adopted in 1911. Its budget for 1926 was \$5,576,945. The Health Department has a staff of 116, including 35 nurses. The Board of Education in 1922 made a thorough examination of the public school plant, and mapped out a building programme to relieve immediately the worst conditions due to the city's rapid growth and the small amount of construction for civilian purposes during the World War; to make adequate provision by 1930; and then to provide year by year for a normal increase of population up to 1940. By 1927, 11 new buildings had been completed. The city's 34 parks have an area of 851 acres; 30 supervised playgrounds are maintained in the summer. There are two municipal golf-courses and six private golf and country clubs; a municipal athletic stadium; a municipal market; and a municipal auditorium seating 6,000.

At the base of Red Mountain, on a campus of 75 acres, is Howard college, a co-educational Baptist institution, which was opened at Marion in 1842 as an academy, and moved to Birmingham in 1887. Its enrolment in 1926-27, exclusive of the summer school, was 987. Birmingham-Southern college, under Methodist auspices, also co-educational, occupies 125 acres on a

hill overlooking the entire city and valley, and had an enrolment in 1926-27 of 1,044 in the college proper. It was created in 1918 by the consolidation of Birmingham College, founded in 1897 as the North Alabama conference college, and Southern university, established at Greensboro in 1859.

In 1870 the site of Birmingham was a cotton field crossed by two railways. The city was founded in 1871, by a land company backed by railway officials, and was incorporated on Dec. 19. It was named after the city of the same name in England. At the census of 1880 the population was 3,086; in 1890 it was 26,178; in 1900, 38,415; in 1910, 132,685. Annexations of territory have increased its area to 53sq. m. Between 1900 and 1926 the population multiplied by 6; bank deposits by 13; value of property by 14; the city's revenue by 16; the number of factories and mines in the Birmingham district by 2½, the number of their employés by 6, and their corporate investment by 9. The water-mains within the city limits increased from 76m. to 649m.; sidewalks from 15m. to 468m.; telephones from 1,433 to 36,145; and motor-vehicles from 12 (in 1905) to 30,602, one to every six of the population.

BIRNEY, JAMES GILLESPIE (1792-1857), an American leader of the political abolitionists (anti-slavery), was twice candidate for the presidency of the United States on the Liberty Party (q.v.) ticket, 1840 and 1844. In the first instance he spent the whole of his time as candidate speaking in Great Britain against slavery in the United States, and in the second he wielded such political power in western New York and elsewhere as to cause the defeat of Henry Clay (Kentucky Whig) and the election of James K. Polk (Tennessee Democrat). But in 1845 a fall from his horse made him an invalid and cut short his political career. Birney was born in Danville, Ky., in 1792, of Scottish-Irish parents; graduated in 1810 at the College of New Jersey (now Princeton university); and was admitted to the Bar at Danville in 1814. Although he held slaves in Alabama, where he lived for a time after 1818, he was from the beginning an anti-slavery Democrat, finally drifting into the Whig party. About 1826 he became interested in the American Colonization society, and in 1832-33 served as its agent in the south-west. He decided, however, that the society's plan was impracticable, returned to Danville to devote himself wholly to the anti-slavery cause, and in 1834 freed his own slaves. On July 15 1834, he published his *Letter on Colonization* and gained a national reputation which carried him into the recently organized American Anti-Slavery society, in which he immediately exerted a decisive influence in favour of "political action."

He became executive secretary of the society in Sept. 1837. In spite of the opposition of the Garrisonian abolitionists, steps were taken at Albany, N.Y., on July 31, 1839, for the organization of an anti-slavery political party; but this caused a split in the American Anti-Slavery Society. Those who favoured political action withdrew from the annual meeting of 1840 and assumed the forms of two organizations; namely, the Liberty Party with Birney at the head of a national ticket, and the American and Foreign Anti-Slavery society for co-operation with British abolitionists led by Joseph Sturge (q.v.). This larger movement developed in a General Anti-Slavery convention, which was called to meet in London, on June 12 1840. Before the work of organization was completed, however, Birney with Henry B. Stanton and others, sailed as a delegate to the general convention, London, taking with them a mass of lecture materials for the instruction of British abolitionists on the economic, social and political bearings of the anti-slavery question in the United States. Birney and Stanton, travelling together much of the time, lectured for about five months throughout the British Isles, laying foundations for an Anglo-American anti-slavery solidarity which endured through the Civil War. He died at Perth Amboy, N.J., on Nov. 25, 1857.

BIBLIOGRAPHY—See E. Channing, *History of the United States*, v. (1921), 545; and T. P. Martin, *Anglo-American Relations, 1829-46* (ms. thesis, 1922, Harvard Library), and William Birney, *James G. Birney and His Times* (1890).

BIRON, ARMAND DE GONTAUT, BARON DE (1524-1592), French marshal, belonged to a family, one of the numerous branches of the house of Gontaut, which took its title from the territory of Biron in Périgord. As a page of the queen of Navarre

Biron attracted the notice of the marshal de Brissac, with whom he saw active service in Italy.

His great services to the royal cause at Dreux, St. Denis, Jarnac and Moncontour were rewarded in 1569 by his appointment as a privy councillor of the king and grand master of artillery. He commanded the royal forces at the siege of La Rochelle in 1572, and four years later was made a marshal of France. From 1576 to 1588 he was almost continuously employed in high command. From 1589 he supported the cause of Henry of Navarre. Biron was killed by a cannon-ball at the siege of Épernay on July 26 1592. His *correspondance*, preserved in the Bibliothèque Nationale, was edited by E. Barthélemy (Bordeaux, 1874).

His son, **CHARLES DE GONTAUT** (1562-1602) duc de Biron, was in high favour with Henry IV. After his father's death Henry made him admiral of France, marshal, and governor of Burgundy. In 1596 he was sent to fight the Spaniards in Flanders, Picardy and Artois. After the peace of Vervins he discharged a mission at Brussels (1598). From that time he was engaged in intrigues with Spain and Savoy, and, notwithstanding, directed the expedition sent against the duke of Savoy (1599-1600). The duke of Savoy promised him his daughter in marriage, though the project was kept secret. His intrigues were suspected, and Henry IV. demanded explanations. Biron made a partial confession, and remained in favour. His plans were apparently much more far-reaching. He approached various malcontents with the idea of organizing risings in different parts of the country. He was suspected in many quarters. But Henry, who had loved his father, was loth to move against the marshal. At length he summoned Biron to Fontainebleau, but could extort no further confession. Biron and Auvergne were arrested. Biron was found guilty of treason, on documentary evidence which showed that he had communicated full particulars of the French army to the duke of Savoy. He was beheaded in the Bastille on July 31 1602. Biron's fate was the subject of Chapman's contemporary tragedy, *The Conspiracy and Tragedy of Charles, duke of Biron*. See Zeller, "La Conspiration de Biron," in the *Comptes Rendus* (1879) of the Acad. des sciences, morales et politiques.

His collateral descendant, **ARMAND LOUIS DE GONTAUT** (1747-1793), duc de Lauzun, afterwards duc de Biron, played a part in the American War of Independence and the revolutionary wars. Until 1788, when he succeeded to the duchy of Biron on the death of his uncle—Louis Antoine de Gontaut, duc de Biron (1700-1788)—he bore the title of duc de Lauzun. He wrote an essay on the military defences of Great Britain and her colonies (*État de défense d'Angleterre et de toutes ses possessions dans les quatre parties du monde*). In 1789 he was returned as deputy to the states-general by the noblesse of Quercy, and attached himself to the revolutionary cause. In July 1792 he was nominated commander of the army of the Rhine and in May 1793 was transferred to the command of the army of La Rochelle, operating against the insurgents of La Vendée. He was accused by Carrier of *incivisme* and leniency to the insurgents, deprived of his command (July), and guillotined on Dec. 31 1793. Some *Mémoires*, which come down to 1783, were published under his name in 1822 (new ed., 1858), and in 1865 letters said to have been written by him in 1789 to friends in the country, describing the states-general.

BIRR or PARSONSTOWN, urban district, Offaly Co. (formerly King's Co.), Ireland, on rising ground on a branch of the Great Southern railway, by which it is 87m. W.S.W. from Dublin. Pop. (1926) 3,391. Cumberland square is the point from which the several principal streets diverge in regular form. There is a fine castle, housing a famous reflecting telescope. Among institutions the schools of the Brothers of the Presentation Order are noteworthy. Some trade is carried on in corn and timber and in brewing and distilling.

An abbey was founded at Birr by St. Brendan (d. 573), to whom the present parish church is dedicated. The district formed part of Ely O'Carroll, and was not included in King's Co. till the time of James I. A battle is said to have been fought near Birr in the 3rd century between Cormac, son of Cond, and the people of Munster. The castle was the chief seat of the O'Car-

rolls. In the reign of James I. it was assigned to Lawrence Parsons. From him the alternative name of the town is derived. The castle was taken by Ireton in 1650. It also suffered assault in 1688 and 1690.

BIRRELL, AUGUSTINE (1850-), English author and politician, son of a Nonconformist minister, was born near Liverpool on Jan. 19, 1850. He was educated at Amersham Hall school and at Trinity Hall, Cambridge. He went to the bar, and gradually obtained a good practice; in 1893 he became Q.C., and he was professor of law at University college from 1896 to 1899. The publication of *Obiter Dicta* (1884) showed him to be a literary critic of unusually clever style and an original vein of wit. In 1889 he was returned to Parliament for West Fife as a Liberal. In the House of Commons his light but pointed humour led to the coining of a new word, "birrelling." His books on copyright and on trusts were no less sparkling than his literary *Obiter Dicta*. A second series of the latter appeared in 1887. *Res Judicatae* in 1892 and various other volumes followed. In 1888 Mr. Birrell married as his second wife Mrs. Lionel Tennyson, daughter of the poet Frederick Locker (Locker-Lampson). Defeated at North-East Manchester at the general election of 1900, he re-entered Parliament in 1906 for a Bristol division, and as minister for education was responsible for the Education bill, which had ultimately to be withdrawn. Campbell-Bannerman then transferred him to the chief-secretaryship in Ireland, and he introduced the Irish Councils bill, which was killed by its repudiation at the Nationalist Convention. Irish administration became more and more difficult, but Mr. Birrell declined to invoke the Crimes act. He continued to be chief secretary for Ireland until the Dublin rebellion of Easter 1916, a period of over nine years. The cattle-driving agitation died down, and Irish politics, save for labour troubles, were comparatively quiet, until the two general elections of 1910 had once again made retention of office by the Liberal leaders dependent on the Irish vote. A third Home Rule bill was now inevitable, and Mr. Birrell spent much of the autumn of 1911 in preparing it. The main conduct of the measure was, however, taken out of his hands, in the sessions of 1912, 1913 and 1914, by Mr. Asquith, the prime minister.

When resistance was organized in Ulster, when volunteers were enlisted and drilled in the province, and a provincial government constituted, Mr. Birrell adopted the *laissez-faire* attitude which had throughout been the mark of his Irish administration; and he applied the same treatment to the Irish volunteers who were raised in the Sinn Féin and Nationalist interest. With the outbreak of the World War the Home Rule controversy was left in abeyance; and the danger with which Mr. Birrell had to cope came from extremists of the Sinn Féin, Irish-American and Irish Labour parties, of whom Casement and Larkin were the apparent leaders. They promoted a strong and largely successful propaganda against enlistment in Ireland, which culminated suddenly in open rebellion at Easter 1916. Immediately after the suppression of the rising, Mr. Birrell resigned; and he left Parliament and political life in 1918. Resuming his literary work, he published in 1920 a life of his father-in-law, the poet Frederick Locker-Lampson; in 1922, *Collected Essays* in 3 vols.; and in 1924 *More Obiter Dicta*. His originality, satire and ripeness put him at the head of English men of letters on the critical side.

BIRTH. In law, a child not actually born, but *en ventre sa mère*, is supposed for many purposes to be actually born, and may take any benefit to which it would have been entitled if actually born, *i.e.*, it may take as legatee or devisee, or even as next-of-kin or heir, but none of these conditions will take effect, unless the child is born alive (*see* MEDICAL JURISPRUDENCE). The given year of age of a child is gained at the first instant of the day preceding the birthday, and no account is taken of parts of a day. *e.g.*, a child born at 11.59 on the night of May 2-3, 1900, would be of age the first moment after midnight of May 1-2, 1901. In English law, by the Offences against the Person Act of 1861, it is a misdemeanour punishable by a maximum of two years' imprisonment with hard labour, to endeavour to conceal the birth of a child by any secret disposition of its dead body, whether the child died before, after, or at its birth; and by the Infanticide

Act 1922 a woman who causes the death of her newly-born child by wilful act or omission, but had not fully recovered from the effect of the birth, can be found guilty of infanticide (*see* *Rex v. O'Donoghue*, Nov. 1927).

The registration of baptisms is said to have been first introduced by Thomas Cromwell when vicar-general in 1538, but it is only in comparatively modern times that registration has been fully carried out. The law relating to the registration of births for England is to be found in the Births and Deaths Registration Acts 1836 to 1901 and in the act of 1926 which requires the registration of still-births. Before the passing of the Births and Deaths Registration Act 1836, the records of the births were compiled from parish registers, which were formerly a part of the ecclesiastical organization, and continued to be attached, more or less, to the Church till the passing of the act of 1836. That act provided a far more complete machinery than that before existing for the exact record of all births. The new system relieved the clergy from all functions previously thrown upon them, and finally, after improvement by subsequent acts, was made compulsory in 1874. The act of 1836 established a general register office in London, presided over by an officer called the registrar-general, with general superintendence over everything relating to registration.

By the Births and Deaths Registration Act 1874, which amended and consolidated the law, it is the duty of the father or mother of any child born alive, or in their default, then of the occupier of the house (if he knows of the birth) or of any person present at the birth or having charge of the child, to give to the registrars under penalties within 42 days after the day of the birth, information of the particulars required to be registered concerning the birth, and in the presence of the registrar to sign the register. After three months a birth can only be registered in the presence of the superintendent registrar, and after the expiration of 12 months a birth can only be registered with the written authority of the registrar-general. In the case of an illegitimate child, no person as the father of such child is required to give information, nor is the name of anyone entered in the register as the father of such a child, unless at the joint request of the mother and the person who acknowledges himself to be the father. An additional duty is placed upon the father by the Notification of Births Act 1907. By that act it is the duty of the father of a child, if he is actually residing in the house where the birth takes place at the time of its occurrence, to give notice in writing of the birth to the medical officer of health of the district in which the child is born within 36 hours of the birth. The same duty is also imposed upon any person in attendance, *i.e.*, medical practitioner or midwife, upon the mother at the time of or within six hours after the birth. The medical officer of health is then in a position to take such steps, by advice or otherwise, as may, in his opinion lead to the prevention of infant mortality. Notice under the act is given by posting a prepaid letter or postcard to the medical officer of health giving the necessary information. Failure to give notice entails on summary conviction a penalty not exceeding 20 shillings. The act was optional to local authorities, but might be enforced within any area by the Local Government Board, but now by the Notification of Births (Extension) Act 1915 the system is made universal throughout the country. By the Births and Deaths Registration Act 1874 and the Merchant Shipping Act 1894, commanding officers of ships trading to or from British ports must, under a penalty, transmit returns of all births occurring on board their ships to the registrar-general of shipping, who furnishes certified copies of such returns to the registrars-general for England, Scotland and Ireland. These returns of births (and deaths) constitute the "Marine Register Book."

As to the Registration of Births of Legitimated Persons, *see* the Legitimacy Act 1926.

Following the provisions of the Non-Parochial Registers Act 1840, which made it a felony wilfully to destroy or injure a register or record of birth and is still unrepealed, by s. 36 of the Forgery Act 1861, as amended by the Forgery Act 1913, unlawfully destroying, defacing or injuring any register of births, or knowingly inserting in such register any false entry, or giving

a false certificate relating to any birth, is a felony and the punishment penal servitude for life. By s. 3 (2) of the Forgery Act 1913, forgery of any register of births, if committed with intent to defraud or deceive, is a felony punishable with penal servitude not exceeding 14 years; and by s. 3 (3) forgery of any certificate, declaration or order under any enactment relating to the registration of births with a like intent, is a felony and the maximum punishment seven years' penal servitude. Also by s. 4 of the Perjury Act 1911, wilfully making any false statements or declarations or certificates as to births or still-births is made a misdemeanour punishable on indictment with a maximum sentence of seven years' penal servitude and on summary conviction by a fine not exceeding £50, this sum having been increased from £10 by the Criminal Justice Act 1925.

BIRTH CONTROL. This term is the popular name for control of conception, the deliberate restriction of births by chemical and mechanical means, instead of by abstention from intercourse. The term was probably first used by Mrs Margaret Sanger in *The Woman Rebel* (April 1914).

The use on a large scale of contraceptives is a modern phenomenon. The prosecution in 1877 of Charles Bradlaugh and Annie Besant, for selling, in order to establish freedom of publication, a pamphlet by Dr. Charles Knowlton entitled *The Fruits of Philosophy*, gave enormous publicity to birth control methods, and a Malthusian League, with Dr. Drysdale as president, was immediately established to continue the propaganda in favour of small families. The League started a periodical, and Dr. Drysdale and his wife, Dr. Alice Vickery, devoted their lives to writing and lecturing on the need of spreading the knowledge of contraception, especially among the poorest class.

They maintained that the two fundamental needs of food and love could be satisfied only through contraception, and that poverty, sex starvation, and promiscuity could only be avoided by early marriages and small families. In 1881, by their assistance, a Dutch neo-Malthusian League was established, followed by similar leagues in Belgium, France and Germany. In 1921 the League opened a clinic in South London, where a doctor instructed poor mothers in the Mensinga method. In 1922 it held in London the Fifth International Neo-Malthusian Conference.

The American Birth Control League was organized in 1921

themselves in a declining birth-rate. Before the 18th century there was nearly a population equilibrium. Between 1750 and 1800 the population of England and Wales rose from 6,500,000 to 9,000,000. In the 19th century, influenced by great national prosperity and the development of preventive medicine, the population rose from 9,000,000 to over 32,500,000. This amazing advance reached its height in 1876. Thereafter a decline in the birth-rate set in which still continues.

Optimum Population.—This rapid population-increase which has taken place within the last 125 years, is a singular event in human history. And it raises the vital question of the optimum population which any country can adequately maintain. In this connection the report of the National Birth-Rate Commission (1916) stated that there is no evidence that the world's population is at present outrunning the natural resources; but on the contrary the presumption is that for their fuller utilization a larger population is necessary, and thereby could be maintained with a higher standard of living. There was, e.g., an increase of 75% in the production of wheat within the British empire between 1901-11 mainly due to the development of western Canada (See Memorandum issued by Dominions Royal Commission 1915).

Another aspect of the decline of the birth-rate in England and Wales is exhibited in the census returns, particularly in the report on the "Fertility of Marriage," vol. 13, 1911. One example may be given: Table 44, which relates only to wives over 45 years of age at the census date, shows that, when necessary allowances are made, children born to 100 couples fell from 738 for marriages entered into between 1851-61 to 632 for those between 1881-86, the latest date to which this particular investigation was made. This shows a decline of over 14%. Later returns show a much greater decline. In 1881, in round figures, 883,600 children were born to 26,000,000 persons, but in 1924 only 729,900 children were born to 38,746,000 persons. The latest decennial supplement of the British Registrar General for 1921, published 1928, gives the occupational mortality, fertility and infant mortality (mortality of 1921-23, fertility and infant mortality of 1921). He says: "Even though three large groups of workers were excluded in 1911 from the five graded classes which are now included in them (coal miners, textile workers, and agricultural labourers) the general lines of distinction have remained so much the same that it is of interest to compare the fertility record of each class in the two census years. This is done in Table 26."

TABLE 26
Comparison of Legitimate Fertility and Infant Mortality in Social Classes, 1911 and 1921

	Legitimate births per 1000 married males under 55 years of age.					Infant mortality.				
	Rate in.		Rate per cent of that for all classes.		Rate in 1921 per cent of that in.	Rate in.		Rate per cent of that for all classes.		Rate in 1921 per cent of that in.
	1911	1921	1911	1921	1911	1911	1921	1911	1921	1911
I. Upper and middle	119	98	73	70	82	76	38	61	48	50
II. Intermediate	132	101	81	74	79	106	55	85	70	52
III. Skilled workers	153	141	94	100	92	113	77	90	97	68
IV. Intermediate	158	102	89	115	103	122	89	98	113	73
V. Unskilled workers	213	178	131	126	84	153	97	122	123	63
All classes	162	141	100	100	87	125	79	100	100	63

under the presidency of Mrs. Sanger. Due to her efforts, similar leagues have since been organized in Japan, China and India. One of the main activities of the American League is directed toward the removal of federal and state statutes prohibiting instruction in contraception under the direction of duly licensed physicians, and aims at the eventual establishment of clinics for scientific and hygienic instruction of parents. The work of the federal legislation was however initiated in 1919 by the Voluntary Parenthood League.

Under the auspices of the American Birth Control League, Inc., the Sixth International Neo-Malthusian and Birth Control Conference was held in New York city, March 1925.

Decline in the Birth-Rate.—The results of these and similar efforts, of course in addition to other causes, quickly showed

It will be seen that at both periods fertility stood in this way increased continuously from Class I. to Class V, being nearly twice as high in the latter as in the former, and for every class except IV. it is shown as having fallen in 1921. This apparent exception is doubtless due to inclusion with the five graded classes of the three groups of workers previously excluded. Large numbers of coal miners and agricultural labourers, whose fertility is above the average, have been added to Class IV. and it may be presumed that this change in classification accounts for the increase of the rate shown for Class IV. Apart from this the general picture is one of all-round decline. In view of the changes between the two periods in occupational and social classification it would be unsafe to attribute significance to the minor variations recorded.

These data, said the report of the National Birth-Rate Commission, amount to a complete statistical demonstration that fertility is closely correlated with social status. The more prosperous the social class the lower is the fertility. This initial difference is not removed by subsequent differential mortality in the offspring in favour of the more wealthy classes.

America and Australia, like Europe, have the same problem to face, and there is evidence that the same phenomenon can be observed in India. No doubt, special causes play a part in each case. In France the provisions of the Code Napoleon, which insist on the division of property tend in the same direction. Social difficulties connected with religion operate in India.

Thus a differential birth-rate has arisen as a consequence of the practice of restriction by the higher social classes. For a population to maintain its numbers unaltered it is necessary, Prof Whetham estimated, that families should consist of "not less than four children." A nation which produces three children to the fertile marriage has, therefore, a birth rate of three-quarters of that necessary on this basis to maintain its position.

As regards the quality of population of the world, the prime question arises "Have we any reliable criterion of desirability in respect of races and race blends? Is there any evidence that a mispopulation of the earth is taking place, in the sense of a refusal of 'higher' and intrinsically fitter races to multiply, while lower and intrinsically less fit peoples are spreading more numerously over the earth?" The necessary limitations of our knowledge about human qualities and their relative values for the civilization of the future, as well as our racial and patriotic biases, render it impossible to give a confident answer to these vital questions. There is recent evidence to indicate that the supposed differences of inherent racial qualities are much slighter than has been alleged, and that education and cultural environment explain the greater part of what we considered ethnical differences.

National Birth Rate Commission.—In 1916 the British National Council of Public Morals established the National Birth-Rate Commission (some of whose findings have already been quoted), with the recognition of the British Government which allowed Dr. T. C. Stevenson, the superintendent of statistics, and Sir Arthur Newsholme, its principal medical officer, to serve as members.

The Commission, which consisted of 43 members representing medicine, science, economics, and statistical, educational and religious interests, issued its first report in 1916, entitled *The Declining Birth Rate, its Causes and Effects*. A second appeared in 1920, on *Problems of Population and Parenthood*; a third in 1921, on *The Prevention of Venereal Disease*; and a fourth in 1923, entitled *Youth and the Race*. The Commission heard over 70 expert witnesses on all aspects of these problems and published for the first time the views of the Catholic Church, the Church of England and the Free Churches on the ethical aspects of birth control. The Commission's enquiry was made in four directions: (1) the extent and character of the decline; (2) the alleged causes; (3) the effects; (4) the economic and national aspects. These reports were presented to the various departments concerned, the Ministry of Health and the Board of Education; and extensively circulated and reviewed throughout the British empire and America. Mr. Sidney Webb described the report thus:

"The Commission has produced the most candid, the most outspoken, and the most impartial statement that this country has yet had as to the extent, the nature, and the ethical character of the voluntary regulation of the married state which now prevails over the greater part of the civilized world."

Economic Aspect.—In the section of the report dealing with the economic aspect some expert witnesses maintained that there is no sufficient reason to conclude that the reduction of the birth-rate of Great Britain has been inimical to the well-being of the nation. Others maintained that if a higher birth-rate or a check upon further reduction be deemed desirable, or if an improvement in the character of the birth-rate can be obtained, such reforms would be facilitated by certain social-economic changes—amongst which are greater security and regularity of income, equalization of opportunities for education and for technical and

professional training, conducive to a greater equalization of income and of standards of living—not only would reduce the extreme risks of poverty, but would weaken those motives of mingled timidity and social ambition which, especially among superior artisans and the middle classes, promote late marriages and small families. The physical and mental inferiority of the most fertile social strata, except in the mining districts, is indisputable; but the Commission stated that the greater part of this class inferiority is probably due to bad environment, and it deprecated the tendency to identify the economic élite with the psycho-physical élite. It could not accept the hypotheses that the broad distinctions between the social classes are but the effects of germinal variations, and is satisfied that environmental factors which cannot be sensibly modified by individuals exposed to them, however gifted, often prevent the utilization of natural talents. Some have advocated State bonuses for families, in the form of State-aided insurance when the earnings do not amount to £200 a year, for all children who attain the age of 14 years to secure further education and a better start in life. The means of husband and wife should be considered separately in computing income-tax, as the present arrangement penalizes marriage; within the range of incomes, say below £700 a year, there should be substantial remission of the tax on parents for each child. Facilities for a good cheap education above the standard of the elementary school should be greatly increased; and in all schools scholarships or aided education should be given to children of large families.

The degree of the value of human life depends on its inborn character and its environment. An increase of population in a given country is, therefore, good unless by reason of its size and constitution it definitely lowers the normal standard. The strongest argument *prima facie* in favour of restriction is the working class contention that large families, so far as they imply an increase in the number of wage-earners, tend to reduce wages or to prevent their increase, so favouring a restricted distribution of wealth injurious to the normal standard of life. A few years ago the Women's Co-operative Guild, which had a membership of 32,000, instituted an enquiry amongst working women upon their maternal experiences. The report is a human document of much value. It contains the letters of many working women detailing the conditions as to their food, rest and medical care before child-birth. These conditions in the large majority of cases were so bad that the report concluded: "These letters give the skeleton of individual lives and individual thoughts and feeling; but in these facts and thoughts and feelings one can see clearly the general mould of life and the sweep of the current of general opinion which is among the working classes, resulting in the refusal to have children."

Inadequate housing accommodation is regarded as one of the chief causes of restriction. This has necessarily been accentuated by the World War, and for some years to come the deficiencies cannot be made good, and must continue to be inimical to the normal and desirable growth of a healthy population.

In dealing with the wider problem of birth control, the Commission said that when we look beyond our own shores the possibility of an increase along with improvement of the population becomes manifest. There are vast territories in Canada and Australia which are very sparsely peopled, and are not yielding in food for human sustenance and raw material for human industry what they might. The rise of prices throughout the world can be met only by a much fuller development of the incalculable natural resources of such lands, a development which is waiting an increase of population. Can we resist the pressure of Asiatic immigration without provoking antagonism, if not worse, while we are not making full use of the lands which we are resolved to keep "white"? If we value our national type should we not desire its diffusion, for the sake even of the backward types, that they may be advanced by our influence to a better standard of life and thought? Britain must, in view of these considerations, regard with gravest concern her falling birth-rate, and take such practical steps as may be within her power to arrest the decline, and, if possible, restore the rate to a higher figure. That an increase in quantity is desired is clear, but it must be an increase in quality

as well. The crux of the problem is to increase the supply from good stocks, precisely the stocks which possess the important qualities of foresight and self control. It cannot be supposed that the Dominions will accept emigrants from feeble stocks, which there, as here, become a burden on the industrious. Their statesmen are anxious to avoid that catastrophic condition in which—

By filching all the substance of the fit
We make the rotten multiply on it.

Immigration.—As against those who look to emigration to under-populated countries to relieve the economic pressure in over-populated lands, it has been urged that if all barriers to emigrants were removed, the vacant spaces would fill up within a century, and the over-populated lands would again be over-populated. Moreover, it is contended the under-populated countries have an undoubted right to require the over-populated to lower their birth-rate before demanding free entry for their surplus stock.

Propaganda.—Birth-control propaganda received another impetus from the enormous sale of the writings of Dr. Marie Stopes and from her libel action against Dr. Halliday Sutherland. A Society for Constructive Birth Control with a mother's clinic was established by Dr. Stopes and her husband. In 1923, Dr. Stopes published an exhaustive treatise on birth control entitled *Contraception, its Theory, History and Practice*.

In 1924, The National Birth-Rate Commission established a special committee, consisting of representatives of medicine, public health, education, sociology and religion, under the presidency of the bishop of Winchester, to investigate further the ethical aspects of birth control. This report was published in May 1925, together with the evidence taken. Four of the conclusions of the committee may be quoted.—

(1) The use of contraceptives is a symptom of the artificial character of our civilization whereby for large numbers of people a simple, healthy, normal married life is difficult, and in some cases all but impossible. (2) There are numerous cases in which control of conception, considered in itself and apart from the question of the methods employed, is medically necessary and economically advisable, but in every such case all the circumstances should be weighed in the light of the best available scientific and ethical counsel. (3) The ideal method of birth control is self-control. Such self-control must be agreed upon by husband and wife and be carried out in a spirit of service and sacrifice. Therefore, so far from giving any general approval to the use of contraceptives, the line of real advance lies in a deeper reverence, a return to greater simplicity of life and, not least, a drastic reformation of our social and economic conditions. (4) The weightiest argument for birth control is found in the economic circumstances (wages, grossly inadequate housing, and the like) of many persons. While in many instances birth control by contraceptives may be the lesser of two evils, the ultimate remedy lies in the amelioration of these conditions.

Medical Enquiry.—The report was followed up by a strictly medical enquiry established by the National Birth Rate Commission. This medical committee was conducted by 13 well-known experts in medicine and physiology, and presided over by Charles Gibbs, F.R.C.S. (senior surgeon to Charing Cross hospital and to Lock hospital), Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P. (late chief medical officer, Local Government Board; late lecturer on hygiene and public health, Johns Hopkins university, Baltimore).

The terms of reference to the medical committee were.—

1. In using the term "medical" it is intended to make an investigation into the restriction of families by whatever methods it is accomplished and its effect on the bodily and mental health of the individuals concerned.
2. Under the term "Health" are included the relevant biological (physiological and psychological) factors which affect the normal life.
3. Among the particular problems which it is proposed to investigate are:—
 - (a) the medical reasons for the exercise of conception control;

- (b) the effect on health of sexual abstinence, partial or complete, in married life;
- (c) the reliability as a preventive against conception of the so-called "safe period" with the relevant physiological and biological problems;
- (d) the effect of the use of various contraceptives on

(i) the subsequent fertility	}	of the persons concerned
(ii) the health		

The committee took evidence from a number of expert witnesses and from the medical representatives of various birth control clinics. Their report states.—

On the subject of statistical data regarding the efficiency of contraceptives the amount of scientific knowledge as to the efficiency of contraceptives based on statistical data is very small. On this subject exact information could only be based on the collection of scientific data extending over a period of years. Such statistics would have to be accurately compiled from reliable observations extending over the whole period of the reproductive life of men and women.

American witnesses have helped the committee by reporting the organization of a scheme in New York for investigating contraception from every point of view. Some years must elapse before results on a considerable scale can be expected.

Apart from possible data hereafter obtainable from the scientifically organized investigations adumbrated in that scheme, the committee are unable to regard as satisfactory many statistical statements as to the relative success or failure of various contraceptive methods for preventing pregnancy. The statistics which have come to their knowledge have not been compiled in such a manner as to give confidence in the results as stated.

Before giving their own conclusions as to this evidence, the committee directed attention to two sources of error which appear to vitiate much that has been written on this subject:—

- (1) A considerable proportion of marriages are sterile apart from disease or from the use of contraceptives.
- (2) In normal experience of married life, the average intervals of child-bearing are much longer than is commonly supposed; and the facts do not bear out the impression that might be gathered from much of the writing on this subject.

In the ordinary married life of the young, usually an interval of about two years elapses between births, and after the age of 30 this interval usually increases. This has been the experience of large communities before modern "birth control" was known. Hence to speak of an "avalanche of babies" as almost inevitable unless special preventive measures are taken is inaccurate and misleading. The above statements represent average experience, in cases of too rapid child-bearing special advice is desirable.

In view of the above facts, the medical committee have little doubt that contraceptives are frequently employed when, if they were not employed, conception would not occur.

Medical Committee's Conclusions.—Subject to the above considerations and to the fact that the committee are attempting to base their opinions exclusively on medical grounds, they arrived at the following conclusions.—

- (1) That the prevention of conception is being attempted by a large number of individuals.
- (2) That this number is probably increasing rapidly.
- (3) That the reduction in the birth-rate is partially, and perhaps chiefly, due to the increasing use of contraceptive methods.
- (4) That judging from experiments on animals, diet may have an influence on fecundity in human beings, though, in view of the variations of fecundity in different communities in which no difference of diet has been detected, this remains to be proved.

Methods.—The medical committee considered in detail the various methods advocated. Abstinence, operative measures, condom or sheath, pessaries, coitus interruptus, the safe period, irradiation of the ovaries by radium or X-rays. The reader is referred to the report mentioned below for their findings. They received evidence pointing to the effects of certain diet deficiencies on fertility and considered the effects of the use of contraceptives on the health of individuals.

Men may be psychically upset by the use of a mechanical contraceptive agent; they may be temporarily less potent or impotent, but generally speaking their health does not suffer. Further, there is always the danger that if a man by using contraceptive methods is not fully satisfied sexually, domestic happiness may be ruined by his seeking satisfaction by other means or elsewhere, and with the risk of contracting venereal disease.

With regard to the woman, evidence brought before the medical committee suggests that in cases in which, on medical grounds or on account of an already large family, contraceptives are advisable, their use brings about an improvement in general health owing to freedom from anxiety as to the possibility of pregnancy, increased happiness in the home, better outlook and greater affection for the children. Some women, on the other hand, suffer from irritability of temper or more serious effects on the nervous system. It is said that these latter conditions are more common when *coitus interruptus* is practised.

Reasons for the Use of Contraceptives.—The indications for the use of contraceptives include disease of an hereditary character, such as some forms of insanity, and in addition syphilis, incurable diseases such as non-compensated heart disease, Bright's disease and tuberculosis; also conditions that make child-bearing dangerous, such as pelvic deformity, tumours, severe debility and varicose veins, caused by frequent child-bearing.

Poverty, deficient housing accommodation, etc., are not within the scope of a medical enquiry.

General Remarks by the Medical Committee.—The committee says that the entirely successful contraceptive, one that would be sure, harmless and simple, has not yet been discovered. The difficulty of the committee was to ascertain the true efficiency of any method, as each one of the important methods is supported by its own particular advocate.

Where the use of contraceptives is called for, discrimination in the methods to be employed is necessary. Two important factors are the questions whether the avoidance of conception is to be temporary or permanent, and whether it is to be regarded as essential or merely expedient.

"We are of opinion," says the medical committee, "that no impediment should be placed in the way of those married couples who desire information as to contraceptives, when this is needed for medical reasons or because of excessive child-bearing or poverty. In this matter the welfare of the family, and especially of the children, should determine the common practice; and this welfare is not secured when there is only one child, or where too long intervals elapse between the birth of children."

This medical enquiry was followed in 1928 by an economic enquiry by the same Commission.

Biological Arguments for Birth Control.—The biological arguments in favour of birth control and for the education of married citizens and of those about to be married in the use of contraceptive methods for worthy ends are stated as follows, by Dr. C. J. Bond, F.R.C.S., a member of the above medical committee:

"The world is gradually filling up with a heterogeneous population in which *innate*, as opposed to *acquired*, mental and bodily characters vary greatly, not only in different races and nations, but also in different individuals, in different groups and social levels in the same nation.

Further, inasmuch as the propagation of these varying capacities, these good and bad qualities, from generation to generation, is no longer determined by natural selection only, but has passed under human control, it becomes of the utmost importance that such artificial control shall be directed along right lines to worthy ends, that is, to ends which make for racial improvement and not for racial decay.

Among the factors which exercise a great influence over the future of mankind that of the quality of the human life produced is the most important.

The mental attitude therefore which regards the exercise of any voluntary control over the production of offspring (otherwise than by prolonged abstinence, which is impracticable and may have serious consequences in the case of young, normally con-

stituted married persons) is one which fails to recognize the great change which has occurred in the method of human evolution, whereby natural selection has been largely superseded by artificial selection under human control.

But before man can exercise any effective control over the quality of human life produced he must be able in some measure to control its quantity also. He must also be able to determine not only the number of children in each family, but also the intervals between each birth.

The growth of physiological knowledge concerning the conditions under which fertilization normally occurs, and of the means by which it can be prevented, has placed within man's reach the possibility of controlling the number and rate of production of offspring. This is a necessary step towards the attainment of control over the quality of offspring produced. But it is also essential that this recently acquired knowledge should be applied to worthy ends. It is freely admitted that such knowledge may be used, and in some cases is at present being used, for selfish and unworthy ends. The remedy however does not lie in the curtailment of knowledge, but in its wider spread to all sections of the married population, poor as well as rich.

At the same time, and along with this diffusion of knowledge as to the methods of contraception, must also go sound instruction, reinforced by religious and moral appeals, concerning the responsibility which rests on all married citizens of normal capacity and sound parentage to set racial before individual interests, and to fulfil, with due regard to hereditary conditions and environmental circumstances, their duty as parents to the next generation.

Under modern conditions of life it is not possible in many cases to carry out the duties satisfactorily without the exercise of control over fertility.

It may be that the methods of contraception as now practised will give place in the future to more refined, more effective, and better methods as our knowledge grows."

The Religious Problem.—It is now recognized that the objections on religious grounds to birth control must be fully faced. These objections can be best stated by taking the position of the Roman Catholic Church which is shared by many other religious communities. His Eminence, Cardinal Bourne, archbishop of Westminster, has had the following outline specially drawn up for this article, and it may be taken to express on the highest authority the religious objections:—

"The teaching of the largest organized body of Christians in the world has an inherent interest of its own. The Catholic doctrine is embodied in the constant and universal tradition of the Church, and has been the subject of repeated instructions from the Holy See. It is not a matter of theological opinion, but is the considered judgment of an authority which every Catholic knows cannot err in defining Christian morals. For a Catholic this is sufficient, but if a reasoned analysis of the position is desired, it may be explained as follows:

"i. There is no law requiring married people to have large families and if they wish to live in continence they are entitled to do so, but they are absolutely forbidden to exercise the act of generation and frustrate its natural purpose. Birth prevention is prohibited because it is wrong, with an initial fundamental wrongness antecedent to any ecclesiastical law or tradition. The prohibition is based on a principle of natural morality, which no human authority can change or dispense, and which can be accepted by non-Catholics, provided their moral conduct is not based on an ethical philosophy at variance with Christianity.

"ii. Just as certain physical laws govern non-rational things, so also in the human being there is a law regulating the exercise of his faculties and the satisfaction of his desires, whether individual or social. In his free and deliberate movements man should act in accordance with the law of his being, which because of this distinctive element of freedom is called the "moral" law; actions performed in harmony with it perfect his nature and are morally good; those which disregard it are morally bad. The wrongness of certain actions may be demonstrated to some extent by examining their subsequent effects on the individual or on the race. It is a line of enquiry offering a strong contributory

argument, and the physical, domestic and social evils attendant on birth prevention have been indicated elsewhere. But, except on a principle which is frankly utilitarian, it falls just short of a complete demonstration of the wrongness of contraception. This must be sought primarily, directly, objectively and intrinsically in the action itself, not merely in its effects. In a complex organism the good of the whole is achieved by employing the parts each in accordance with its natural purpose. Birth prevention is wrong for the same reason that any other unnatural sexual vice is wrong, namely, because sexual pleasure is gratified in a manner which frustrates the natural purpose of the action.

"iii. The moral or natural law is a participation in the rational creature of the eternal law of God, Who has fixed the sanction of punishment to its non-observance. Birth prevention is supremely evil because it is sin, *i.e.*, an offence against a personal God, the fear of Whom is the beginning of wisdom, and experience shows that the fear of committing sin is the only adequate reason deterring people from this practice.

"iv. An action which is intrinsically and naturally evil can never for any reason be tolerated, no matter how pressing the circumstances which appear to justify it, and no matter how good the intention of the agent may be. Anything short of a rigid and logical application of this principle would be permitting the patently immoral doctrine that the end justifies the means.

"v. The admitted difficulty of observing this law is lessened from the fact that Christian marriage is a sacrament, and the grace it bestows carries with it a title to the special assistance of God, enabling married people to surmount the difficulties of their state, the burden of rearing children, and the observance of continence in circumstances where conception must be avoided at all costs short of sin. It is, moreover, a sacrament symbolizing the union between Christ and the Church (Ephesians v. 25-32), by which human beings, raised to a supernatural dignity, co-operate with God, in peopling Heaven with the sons of God."

In conclusion, it may be said that the problems of the persistent decline of the birth-rate, its causes and effects, and of the widespread practices of contraception, are very complex, and the difficulties tend to become more accentuated with the expansion, and international relations and organization, of industry, the pressure and re-distribution of population, and the increasing demands of modern civilization upon the physical, mental and moral resources of the family and the community. No one nation can deal with such a many-sided problem for itself alone. It has already become a world-wide problem, and international authorities regard its full consideration as one of the primary and urgent tasks of the League of Nations (J. MA.)

Medical Aspects.—Though, obviously, like every other question, the subject of birth control can be approached from a strictly scientific point of view, it is extremely difficult to do this owing to the peculiarly intimate and secretive character of the sexual function in man. Probably the view ultimately taken by any individual as to its justifiability or unjustifiability will depend upon that individual's natural characteristics. The biologically minded will not be impressed by theological objections, the naturally religious will minimize biological arguments, while the selfish or self-indulgent will go his or her own way regardless of any abstract sociological, biological, moral or theological views. Intrinsically, there is to many something revolting in the thought of artificial interference with the natural consequences of one of the highest functions of human association and it is difficult to believe that such action, persisted in, does not react injuriously upon the higher attributes of men and women. Here it is probable there lies one of the main points of difference between the biologist and the theologian. The biologist has greater regard for future generations, *i.e.*, the child; the theologian greater regard for the present generation, *i.e.*, the parents.

The medical practitioner holds an intermediate position, but one with greater leaning towards the present generation. He takes men and women as they are, and to a large extent leaves the question of the children "upon the knees of the gods." On the one hand, he recognizes that there are women whose health, happiness and efficiency are being impaired by too frequent preg-

nancies; on the other hand, he sees restless, dissatisfied, neurotic women whose sexual instinct, he has reason to believe, is unduly stimulated without those periods of natural quiescence induced by pregnancy and attention to the newly-born infant, whose maternal instinct is repressed in greater or less degree, whose main interests are social rather than domestic. Primarily, he is not influenced by economic considerations, but, taking as his base line the normal healthy married couple, he feels that the best results for all concerned follow from a wisely restrained natural exercise of the sexual function with the probable result of a medium-sized family. Nevertheless, he is quite prepared to find that the wife, at all events (mainly because of the tedium of pregnancy, the fear of parturition, the restraint imposed by lactation and the care of a young family), leans towards the practice of birth control, and the husband acquiesces from the view that the matter concerns his wife to the greater extent. And this although, from a strictly medical point of view, an opposite course is indicated and recommended. No doubt the immediate question mainly concerns the woman, but it implies a future more than a few years ahead, and then husband and wife are concerned more equally. Children are not to be had for the asking, and many couples who have practised birth control during the early years of married life remain childless to the end, contrary to their wishes, presumably because secondary changes in the generative system have rendered conception impossible (X)

BIRTH-RATE. This rate is usually expressed in terms of the number of births occurring annually in each thousand of the population under review. Thus, if in a population of one million there were 20,400 births in a given year, the birth-rate for that year would be 20.4. The rate thus obtained, known as the "crude" birth-rate, is a positive measure of the reproductive forces which are actually operating at the time in the population to which it refers. From what follows, it will be seen that it is not, necessarily, a sound basis for comparing the relative fecundity of the population of a given area with that of other areas, or even with its own when, in course of time, changes in its age-constitution have taken place. Under conditions in which the only factor was the physiological one, the birth-rate would be determined, firstly by the proportion of women of conceptive ages in any given population and, secondly, as fertility declines with the advance of years, by the proportions of such women at the lower and higher ages.

To make this latter point clear, it may be mentioned that in England and Wales, fertility is highest at ages 18 to 22, and becomes negligible after the age of 45. A thousand women, at ages ranging between 20 and 30 years, in equal proportions, would normally give birth to nearly twice as many children in a year as would be borne by the same number of women equally distributed over the ages from 30 to 40. But the birth rate is influenced by other than purely physiological conditions.

In the greater part of the civilized world, the proportion of children who are illegitimate to the total born is small, so that the proportionate number of married women, and their relative ages, constitute the main factors in the determination of the birth-rate.

BIRTH-RATE

Birth-Rates in Certain European Countries

Year.	England and Wales.	Scotland.	Belgium.	Denmark.	France.	Germany.	Italy.	Netherlands.	Norway.	Sweden.	Switzerland.
1876	36.3	35.6	33.2	32.6	26.2	40.9	39.2	37.1	31.8	30.8	33.0
1901	28.5	29.5	29.4	29.7	22.0	35.7	32.6	32.3	29.6	27.0	29.0
1913	23.1	25.5	22.6	25.6	19.0	27.5	31.7	28.3	25.2	23.1	23.1
1926	17.8	20.9	18.9	21.0	18.8	20.7	27.8	23.8	19.7	16.9	18.2

Other influences, social and economic, come into play with varying force. For example, it is clear, from what has been said, that, if the age of marriage is, for any reason, advanced, the numbers of married women at the most fertile period will be lessened, and the legitimate birth-rate will decline. It is a fairly well-known fact that an advance in the standard of living means later marriage, which shows one effect in a declining birth-rate. Again, in most countries, deliberate restriction of births is practised to a greater or less extent and is, undoubtedly, one of the most potent factors in the rapid decline which of recent years has characterized most countries for which the facts can be ascertained.

If one goes back half a century, it is found that, over the greater part of Europe, the birth-rate stood somewhere near the maximum which it has been known to reach. Excluding France, such evidence as is reliable points to a rise in the birth-rate in Continental Europe in the period after the Napoleonic wars. This was succeeded by a period of declining birth-rates, followed by another increase. Then came the next period of decline, which has continued practically without interruption down to the present time.

Decline Began in the North.—It began in the North, among the Scandinavian countries, where the birth-rate was, if anything, lower than in other countries, extended then to middle Europe, and thence to countries further south. In the exceptional case of France, the birth-rate showed a steady and uninterrupted decline throughout the whole of the last century, falling from 32.2 in the first decade (1801–10), to 22.1 for the last (1891–1900). The following table shows the birth-rate obtaining in a number of European countries in the years 1876, 1901, 1913 and 1926. In the case of Belgium, the rate for 1912 is given in preference to 1913, while for Denmark and Italy the last rate available at the time of writing is that for 1925. For the present century, the period is divided so as to show the nature of the fall before, and after, the great disturbing element of the World War of 1914–18.

The Decline General.—In every one of these countries the figures tell the same tale; it is merely a question of the extent of the decline which differentiates one from another. Nor is this decline peculiar to Europe—if we take a similar survey of the birth-rates in Australia and New Zealand, we find much the same has happened.

Year.	Australia.	New Zealand.
1876	35.9	41.0
1901	27.1	26.3
1913	28.3	26.1
1926	22.9	21.1

Here the fall was stayed at the beginning of the present century, to be resumed again during the last decade. From this table, it will be seen that the positive fall in their respective birth-rates during the 51 years under review has been:—

Germany	20.2	Scotland	14.7	Norway	12.1
New Zealand	10.9	Belgium	14.3	Denmark	11.6
England & Wales	18.5	Sweden	13.9	Italy	11.4
Switzerland	14.8	Netherlands	13.3	France	7.4
		Australia	13.0		

If, however, we take the percentage decline during the period covered, the order becomes:

England & Wales	51%	Belgium	43%	Italy	29%
Germany	49%	Scotland	41%	France	28%
New Zealand	48%	Australia			
Sweden		Denmark	36%		
Switzerland	45%	Norway			
		Netherlands			

In the whole of the countries under review, with the exception of Australia, New Zealand, France and Italy, the decline during the present century has been much more rapid than it was during the 25 years preceding. It is unfortunately impossible to give similar figures for the United States, as the area in which births are registered has only recently included more than half the population of that country. In 1917 when the births related to over 50% of the total population, the rate was 24.7; in 1924, when it related to over 75%, it had fallen to 22.6, so that it appears that the declining trend is also evident in that country. All these figures relate to the white European races, and it is not easy to give reliable statistics for races of a different stock.

Japanese Figures.—For Asia, those for Japan are probably the best available and are here given:—

	1886.	1901.	1913.	1924.
Birth-rate	27.3	33.1	33.2	33.8

The notable rise shown between 1886 and 1901 is probably due to improved registration rather than to a great increase in births.

It will be seen, however, that during this century this rate has been practically constant, and exhibits none of the declining tendency which is so widely spread among Europeans. In Ceylon, with a population made up mainly of Sinhalese, the rates were:

	1901.	1913.	1926.
Birth-rate	37.5	38.6	39.1

This gives a slight rise over the first quarter of the present century. From the foregoing, it is evident that birth-rates vary, not only in terms of time, but also from area to area, from country to country, from race to race. The tables already given show European rates in 1926 ranging from 16.9 in Sweden to 27.8 in Italy, the latter being over 60% higher than the former. The Japanese rate is exactly double that obtaining in Sweden, while that for Ceylon is considerably more than twice that of England and Wales. Again in the United States, in the year 1924, the birth-rate for the coloured population was 27.4 as contrasted with a rate of 22.2 for whites. In the colony of Jamaica, with an overwhelming preponderance of the coloured element, the birth-rate in 1925 was 34.6, or nearly double that of the mother country.

As has been already stated, these crude birth-rates should not be used as standards for comparing fertility, but they show how far the forces of reproduction are functioning in the countries to which they relate, and for this purpose are indispensable. A rate based on the numbers and proportions of married women of conceptive ages is a better standard for comparing fertility—but it is a fertility rate and not a birth-rate. Moreover, to serve its purpose effectively, it must be weighted and corrected to allow for the differing proportions of the younger to older women in the populations under review. It is not possible in the compass of an article of this nature to discuss the various theories which have been and are still being put forward to account for some part of the variations shown. Brief mention may, however, be made of one or two. The birth-rate is in inverse ratio to the social scale—it is highest among labourers, etc., and lowest among the professional classes. One obvious cause is that the marriage age is much higher among the professional classes than amongst the unskilled workers.

Again, in England and Wales it was highest in the mining areas, and lowest in those carrying on the textile trades, or engaged in agriculture. Early marriage amongst miners and late marriage amongst agricultural labourers again accounts for much of the difference between these two classes. In the textile industry the employment of large numbers of married women in the factories may tend to lower the birth-rate. As for the question of birth-

rates in urban and rural areas, the evidence is conflicting. In England and Wales the birth-rate is highest in the country boroughs and lowest in the rural districts, but this experience is reversed in other countries.

One curious fact is that there is a preponderance of male over female births in European and Asiatic countries, and as to this reference should be made to the article on **SEX RATIO AT BIRTH AND DEATH**.

(S. DE J.)

BIRUNI (ABU-R-RAIHAN MUHAMMAD AL-BIRUN) (973-1048), Arabian scholar of Persian parentage, was a Shi'ite in religion. He pursued the study of history, chronology, mathematics, astronomy, philosophy and medicine. He corresponded with the Ibn Sinā (see **AVICENNA**), and the answers of the latter are still preserved in the British Museum. He went to India, where he taught Greek philosophy and learned that of India. In 1017 he was taken by Mahmūd of Ghazni to Afghanistan, where he remained until his death in 1048.

An English translation of his *Athār ul-Bākiya* under the title of *Chronology of Ancient Nations* appeared in 1879, and his *History of India* was issued in English in 1888.

BIBLIOGRAPHY.—See C. Brockelmann, *Geschichte der arabischen Literatur* (Weimar, 1898), vol. i. pp. 475-476.

BIS (Lat.), twice. A term employed in music to signify, when printed in a score, that the passage in question is to be repeated; also used by French audiences as an exclamation equivalent to "encore."

BISALTAE, a Thracian people on the banks of the lower Strymon, in the district between Amphipolis and Heraclea Sintica on the east and Crestonice on the west. They also made their way into the peninsulas of Acte and Pallene in the south, beyond the river Nestus in the east. Under a separate king at the time of the Persian wars, they were annexed by Alexander I. (498-454 B.C.) to the kingdom of Macedonia. At the division of Macedonia into four districts by the Romans after the battle of Pydna (168 B.C.) the Bisaltae were included in Macedonia Prima (Livy xlv. 29).

Their country was rich in figs, vines and olive trees; the silver mines in the mountain range of Dysorum brought in a talent a day to their conqueror Alexander. The Bisaltae are referred to by Virgil (*Georgics*, iii. 461) in connexion with the treatment of the diseases of sheep. The fact that their eponymus is said to have been the son of Helios and Ge points to a very early settlement in the district.

BIBLIOGRAPHY.—See M. Ihm in Pauly-Wissowa's *Realencyklopadie*, iii. part 1. (1897).

BISBEE, a mining city of Cochise county, Arizona, United States, on the Southern Pacific railway, 7m. from the Mexican border. The population in 1920 was 9,205; in 1927, including the residential suburbs of Warren and Lowell, it was estimated locally at 18,000. The main street, which is a section of Federal highway 80, runs along a canyon 5,300ft. above sea-level, and the city has spread up the slopes and over the still higher adjacent plateaux. Three of the largest copper mines of the country are here. The mines of the Bisbee district employ 3,000-3,500 men, and ship thousands of pounds of ore daily to the smelters at Douglas and elsewhere. Their total recorded production through 1925 amounted to 3,315,157,000 lb. of copper, besides silver, gold, lead and zinc. A striking landmark is "The Pit," a hole several hundred feet deep and covering 18ac., which has been excavated out of the solid copper ore of Sacramento Hill.

BISCACHA: see **VISCACHA**.

BISCAY, a maritime province, and former *seigneurie*, of northern Spain. Pop. (1920), 409,550. The *seigneurie* was vested in the Crown of Castile and Leon in 1379, but the province, like Álava and Guipúzcoa, still enjoys a certain measure of autonomy. In particular the relations of these Basque provinces (*Vascongadas*) with the National Exchequer are governed by special agreements made from time to time. The agreement (*Concierto Económico*) which is in force at present will remain operative for a period of 25 years from Jan. 1927. Of the three Basque provinces, Biscay and Guipúzcoa lie in a zone of hills and low mountains of confused alinement between the Pyrenees and the Cantabrian mountains, and wholly on the northern side of the main

crestline connecting these systems, marked by the Sierra de Aralar, Sierra de San Adrián and Peña de Gorbea (1,538 metres). The third province, Álava, lies to the south of this line, on the plateforms, separated by ranges of hills, which descend step-like to the structural basin of the middle Ebro (see **ÁLAVA**). The confused network of hills in the north and east of the area has undoubtedly contributed to the isolation of the Basque people and to the preservation of their language, which has disappeared from the Alavese plateforms and from the western Biscayan district of Las Encartaciones, bounded on the south by the distinctly lower Montes de Ordiente (800-1,000 metres). Biscay may be defined roughly as the area of main east-and-west drainage by the rivers Cadagua and Ibaizábal, which unite with the Nervión, descending from the Enclave of Orduña in the province of Burgos, to form the estuary on which stands Bilbao. Guipúzcoa is the area of main northward drainage by the rivers from the Deva eastwards to the frontier with France, but the province narrows out in the east to a coastal strip on the lower courses of the Urumes and Bidassoa. The poverty of the soils, derived mainly from sandstones and compact limestones, and the humidity of the climate determine the pastoral character of these two northern provinces. The coast is dangerous to approach, and the rias which indent it are blocked by the alluvium brought down by the rivers; thus harbours are difficult to maintain. The town of San Sebastián is largely built on the alluvium joining broken sections of the Cantabrian coastal platform which is here without human significance.

Biscay is the most important iron-producing province of Spain, the most important lode being that of Matamoros (Somorrostro); 150 million tons of ore have been extracted since the close of the Carlist Wars, and the reserves are now estimated at 60 million tons. Guipúzcoa has several small lodes; at Arditurri four million tons of iron ore have been proved by borings.

Less than 10% of the province is under cultivation, and 80% forest and rough pasture. The farms are small, and the isolated *casertos* or farmhouses are scattered over the hillsides. The main cereal crop is maize (1924, one-third of the cultivated area); apples are the chief fruit crop. But the agricultural production of the province is entirely secondary to its mineral and industrial wealth, and food-stuffs are imported. The humid climate favours the growth of forage plants, and, as in the other Basque provinces, practically all the farmers are also stock-raisers. Livestock in 1924 numbered 218,525 of which 82,287 were horned cattle, bred for milk and meat as well as for labour; the numbers, reduced by exportation during the World War, have been restored by the exertions of the Provincial Authority (*Disputación*), which has fine model stock farms. The forests are managed by the same authority. Fisheries, principally of cod, bream and anchovy, are active along the coast. In mineral production Biscay is second only to Oviedo, iron of fine quality is found in almost every part, and forms a main article of export (1924, 1,991,546 metric tons from the port of Bilbao, 494,202 metric tons from Castro). In 1923 mining employed 8,000 men, and smelting 18,000 men in 21 large foundries, producing iron ore valued at 22,172,976 pesetas, zinc ore 6,270 pesetas, steel 137,155,700 pesetas, pig iron 47,559,540 pesetas, puddled iron 404,800 pesetas, coke 17,819,200 pesetas; the combined values for iron ore, steel and pig-iron being the highest for any province and representing 61.8% of the value produced in those commodities for all Spain. Tinplate, railway rolling stock, chemical manures, soaps and vegetable oils, cement, bricks and tiles, glass, jute and other textiles, preserved foods, dynamite and other explosives, and paper are important products. Mineral spas and springs attract visitors from all parts of Spain. The mining and industrial interests of Biscay have been assisted by the rapid development, since 1870, of railways, and the excellence of the roads, kept up by the Provincial Authority. The inhabitants are enterprising and well-educated; the percentage of illiteracy in 1920 was 22.21, and has since declined. The density of population (489.3 persons per square mile) is the highest in Spain.

Bilbao (pop., 112,819), the capital and principal port, and Baracaldo (26,906), an important industrial district, are described in separate articles. Other large towns are Sestao (15,579), Basauri (11,097), Elorrio (10,045) and Guecho (11,399). The

port of Bermeo (10,517) is the chief fishing station; Durango (5,758), on the Ibaizábal, was founded by the early kings of Navarre in the 10th century, obtained the rank of a countship in 1153, and contains one of the oldest churches in the Basque provinces, San Pedro de Távira; Guernica (4,712), on the river Munda, is celebrated for its oak-tree, still the meeting-place of the representatives of the valleys, although the main business of the meetings has long been transacted in a neighbouring *ermita*. The *Árbol de Guernica* was celebrated by the Basque poet, José María Iparraguirro, in a song which is regarded by the Spanish Basques almost as a national anthem. For the history of the Basques, see BASQUE PROVINCES; for the language, see BASQUE LANGUAGE; for the people see EUROPE.

BIBLIOGRAPHY.—E. J. de Labayru y Goicoechea, *Compendio de la Historia de Bizcaya* (Bilbao, 1903); T. Guiard y Larrauri, *La Industria Naval Vizcaína* (Bilbao, 1917); F. Arnador Carrandi, *El Señorío de Vizcaya y los lugares de Limpias y Colindres* (Bilbao, 1920).

BISCAY, BAY OF (Fr. *Golfe de Gascogne*; Sp. *Golfo de Vizcaya*), an inlet of the Atlantic ocean; bounded on the east and north-east by France, and on the south by Spain. It was called by the Romans *Sinus Aquitanicus*, *Sinus Cantabricus* or *Cantaber Oceanus*, whence the term Cantabrian Sea. The name Biscay is a corrupt form of the Spanish *Vizcaya*. The curve of the bay is broken on the French sea-board by the estuaries of Loire, Garonne, etc. The mountainous Spanish coast has many fjord-like inlets, especially in the west, where navigation is difficult. The bay, with its exposed position and varied currents, is notorious for its storms.

BISCEGLIE (perhaps anc. *Natiolum*), episcopal see, Apulia, Italy, on the east-south-east coast, province of Bari, 21½ m by rail N.W. from Bari. Pop. (1921), 33,905 (town); 38,391 (commune). Three towers, one some 90 ft high, of a strong Norman castle still remain; the cathedral and S. Adorno belong to the same period. S. Margherita (1197) has fine canopied Gothic tombs of the Falcone family.

BISCHOFSWERDA, a town in the republic of Saxony, 22 m. E. of Dresden, in the governmental division of Bautzen. Pop. (1925) 8,757. There are factories for cloth and artificial flowers; also glass-works and potteries; and in the neighbourhood large granite quarries. It is famous as the scene of a battle, May 12, 1813, between the French and the Allies, after Napoleon's retreat from Moscow. It was the residence of Benno, bishop of Meissen, in the 11th century, and the "Bishop's Road" still runs from here to Meissen.

BISCUIT. The variety of products embraced by the term biscuits has shown a marked increase since the beginning of the 20th century, and the output of the large modern biscuit factory includes a great number of specialized articles of which the composition and methods of manufacture differ very widely. In the United States manufactured biscuits are known also as "crackers."

The materials which can be used in biscuits are numerous and of these wheat flour is the most important. The choice of a flour for biscuit-making depends entirely on the kind of product required, thus for the plainer varieties, of which "Osborne" is an example, a weak flour, *i.e.*, one which contains only a moderate amount of soft elastic gluten and may be described as the opposite of a good bread flour, is very suitable (*see* BREAD). The efforts of agriculturists to produce an English wheat containing more gluten of a tougher variety tend to produce a flour which, while more suitable for bread manufacture, is far too "strong" for the simpler types of biscuit. Wheaten wholemeal is used in making goods of the "digestive" type, and other cereal products such as oatmeal, ryemeal, cornflour, riceflour and maltflour are used to give variations in flavour, bite, and appearance.

Sugar in its many forms is a very important ingredient, different effects being produced by varying the kind of sweetening matter. Highly refined cane or beet sugar is milled to a fineness suitable for the end in view, while all varieties of pieces, demerara and raw sugar are used to give a richer flavour when desired. Syrups of all grades, from golden syrup to molasses, are ingredients in gingerbread and other biscuits, whilst honey and malt extract may be used to give distinctive flavours. Since the be-

ginning of this century, the number of materials available for producing shortness has increased. Butter, lard and oleo, the chief ingredients of this kind, are used largely in factories where quality and nutritive value are considered before the cost of the finished article. Nevertheless, the discovery of new vegetable fats and oils and the advance in the knowledge of the methods of refining them have resulted in the production of many compound fats which are available for use in the cheaper grades of biscuits. Other ingredients include eggs, fresh milk, condensed milk, milk

A FEW OF THE STEPS INVOLVED IN MAKING BISCUIT WITH MACHINERY
The dough passes on an endless travelling band to the rollers, which reduce the thickness of the slab. After passing between another pair of rollers, which give the correct thickness for the particular biscuit to be made, it comes under the cutters to be stamped into shapes, and from there is carried to the oven.

powder, dried fruit, cheese, coconut, almonds, spices and flavouring essences. The careful preparation of raw materials for use, by dressing, washing, etc., is of great importance, and chemical analysis of all ingredients is necessary to maintain the purity and quality of the finished product.

Aerating agents are used in small quantity to make the biscuit light, their work being to produce gas within the dough whereby the gluten is expanded. In the case of fermented goods the aerating agent is yeast, otherwise baking-powder composed of a mixture of bicarbonate of soda and tartaric or other acid is used. These two substances, acting together, give rise to the gas, carbon dioxide, necessary for the lightening of the dough. Biscuit factories must of necessity carry a large stock of a variety of ingredients, and the storage of these under suitable conditions, no less than the regulated supply of them to the mixing rooms, calls for careful organization.

Manufacture of Biscuits.—The manufacture of biscuits of the plainer type may conveniently be carried out as follows: Flour is delivered to the top floor of the factory and is put through a sieve to prevent any foreign matter, such as pieces of sack or string, from finding its way into the biscuits. Thence it falls down a shoot to the floor below direct into large scale-pans. Other ingredients are added in the required quantity and the whole is delivered from the base of the scale-pan into a large mechanical mixer on the floor beneath. The requisite amount of water or milk is allowed to flow down on to the dry materials in the mixer. The mixers are large, drum-shaped iron vessels fitted with a horizontal spindle to which are fixed arms at right angles. The arms steadily revolve, mixing the ingredients and thoroughly kneading the dough. Experience of each different product gives the time required for mixing, and when this has elapsed the front of the mixer is opened and the rough lumps of dough fall into a trough placed underneath, in which they are taken to the brake rollers. These are mechanically operated iron rollers with a reversing motion, the dough being rolled backwards and forwards between them into slabs of uniform thickness and texture. It now passes to the biscuit-making machine where, by means of an endless travelling band of canvas, it is carried forward through rollers which reduce its thickness. Finally, it passes

through a pair of gauge rollers, accurately set to give the correct thickness for the particular biscuit, and moves on till it comes underneath the cutters. These are attached on the underside of a heavy block of metal which automatically rises and falls. Each time the cutter comes down on to the dough a number of biscuit shapes are stamped out. At the same time they are pierced by small points in the cutter called dockers, in order that, in the oven, steam may escape through the holes so formed and thus prevent irregular swelling of the biscuit. The process is continuous and a stream of unbaked biscuits passes on towards the oven. The cuttings, *i.e.*, that part of the sheet of dough which has not been stamped out, are carried back by a second travelling band to the end of the machine to be rolled in with fresh dough. The unbaked biscuits finally tip off the end of the travelling band on to iron trays or wires and are then ready for baking.

The preparation of short doughs, *i.e.*, those containing a relatively large proportion of sugar and fat, is a simpler and quicker process and may be carried out in a variety of machines. A familiar type is one in which two vertical spindles, carrying spirally arranged blades, revolve in a tub-shaped vessel containing the ingredients. Owing to the large proportion of fat in such doughs, it is desirable to complete the mixing in the shortest time possible.

The cream cracker, which contains a moderate proportion of fat, may be regarded as intermediate between the plain water-biscuit and those of a pastry character. The manufacture is usually begun by making a sponge, *i.e.*, a slack dough consisting of flour, water and yeast. The fermentation may be long or short, according to the fancy of the manufacturer. The dough is formed by mixing the necessary flour and fat into the sponge and is then taken to rollers where it is repeatedly rolled and folded over upon itself. The resulting dough, when baked in a quick oven, rises rapidly and gives a product of characteristic crispness. Biscuits resembling pastry are made in a very similar fashion, except that no sponge is used and the proportion of fat is much higher. The manufacture of rusks is similar to the sponge-dough method of making bread, except that the sponge is more strongly fermented and a variety of ingredients may be added to give a product of varying sweetness or richness. The dough is divided, moulded, proved and baked in a similar manner to bread, the product being a bun of any shape or size required. The bun is cut up into suitably shaped slices, which are spread on trays and toasted, giving a crisp product with a very "open" texture.

Cracknels are of interest as being the only product of the biscuit factory which is twice cooked and which may therefore correctly be termed a biscuit (Lat. *bis*, twice, and *coctum*, cooked). The method of manufacture is as follows: the dough is cut out in the desired shapes and these are thrown into boiling water; owing to aeration caused by the heat, they soon rise to the surface and are then skimmed off, plunged into cold water and baked in a quick oven.

Ice wafers, sugar wafers and fancy wafers of various types are manufactured in large quantities in most biscuit factories. A suitable quantity of thin batter made from flour and water is poured on to a square horizontal plate and a second plate of the same size is quickly clamped down on to it, leaving a thin space between the two. The baking is effected in a stove of special design heated by gas. The inside surfaces of the plates are engraved with a suitable pattern, and the batter during baking expands to fill evenly the space between them. When the plates are opened the sheet of wafer is easily dislodged. Whereas formerly the stoves were operated by hand, a machine has now been devised which works on the same principle, but is continuous and rapid in operation. Biscuits ornamented with artistically coloured icing are to be seen in many attractive assortments which are offered for sale. The type of decoration determines the method of application, for whereas for plain icings machines are used, more fanciful designs can only be put on by hand, using stencil plate or icing bag. Amongst the very numerous fancy types may be mentioned the popular cream-filled sandwich biscuit, made by including a layer of sweet cream between the biscuit shells.

Biscuit Ovens.—As a general rule biscuits are baked in travelling ovens. These may be 40ft. to 60ft. in length and are fitted with endless chains which move from end to end of the oven. The chains are so made that the baking trays when placed upon them are carried through and discharged at the far end. The speed at which the goods pass through the oven is controlled by a simple mechanical device, and experience alone will decide the time (anything from 3½ to 25 minutes) which any particular biscuit needs. The temperature is also easily controlled and checked by the use of a high-temperature thermometer. It may readily be imagined that while some goods require a short time in a fierce oven, others may need a longer time in a slow oven. The old brick ovens are gradually being replaced by the gas-heated type. The shell of these is iron and the heating chambers are insulated by layers of non-conducting material. It cannot be said that the gas oven bakes all goods as well as the brick oven fired by coal. In the latter there is a more stable temperature owing to the heat absorbed by the brickwork, while in the gas oven variations are more likely to occur. In view, however, of the increased cleanliness of the gas-fired oven, the smaller space occupied, the ease with which its temperature can be controlled and the fact that the gas can be shut off at night and lit again a short time before baking is commenced, it is likely that the coal-fired oven will gradually disappear. The coal or coke oven is fitted with two furnaces, one to supply top and the other bottom heat. The same result is achieved in the gas oven by two rows of gas burners, one placed above and the other beneath the baking chamber. The temperature of baking varies with the kind of goods, but in general it may be said never to exceed 500°F. On coming out of the oven the trays of biscuits are transferred to racks nearby, where they are left for a time to cool; they are then shot off into deeper trays and taken away for sorting and packing. These operations must be carried out with great care owing to the ease with which breakage may occur. The goods are packed into tins as soon as possible after baking, in order that no crispness may be lost; and tins destined for export are made airtight by soldering down the tops. Labelling is performed by hand or in the case of standard sized tins by machinery. (R T C.)

Home-made Biscuits.—These can be made in great variety; a good recipe for a plain, hard biscuit is as follows. Warm 2oz. butter in sufficient milk to make 1 lb flour into a stiff paste, beat with a rolling-pin and roll out thin and very smooth. Cut into rounds and prick holes with a fork; bake about 6 minutes. The name "biscuit" is applied in the United States to a cake which can be made in the following manner. Rub 2 oz. butter into 1 lb. flour, mix with 1 gill of milk; knead and make into cakes, bake in a hot oven. (X)

American Usage.—In the United States a "biscuit" is a small, round, shortened cake. The base is milk, flour, salt, butter or lard, and baking powder, with no sweetening. Biscuits are often made of sour milk to which soda is added, thus the name "sour milk" or "soda" biscuit. The batter is dropped in spoonfuls on a baking pan and baked until golden brown. The biscuits are eaten hot with butter, honey or preserves. Often the batter is baked in a square pan, cut through the middle, buttered, and served covered with crushed strawberries and whipped cream to make strawberry shortcake.

BISECTOR, a point which divides a line segment into two equal parts (also used in the Latin feminine form *bisectrix*), a line which divides a plane angle into two equal angles; a plane that divides a dihedral angle in the same way, or, more generally speaking, any line or plane that divides any geometric magnitude (like a parallelogram, sphere, or cube) into two congruent parts. In crystallography, it denotes the bisector of the angle between the optic axes.

BISECTRIX: *see* BISECTOR.

BISHARIN: *see* BEJA.

BISHOP, SIR HENRY ROWLEY (1786–1855), English musical composer, was born in London on Nov. 18, 1786. He studied with Francisco Bianchi, and his first work, a collection of 12 glees and some Italian songs, shows his master's influence.

After various earlier efforts the *Maniac*, an opera written for the Lyceum in 1810, established his reputation, and probably secured for him an appointment for three years as composer for Covent Garden theatre. The numerous works—operas, burlettas, cantatas, incidental music to Shakespeare's plays, etc.—which he composed while in this position, are, however, in great part forgotten. The most successful were—*The Virgin of the Sun* (1812), *The Miller and His Men* (1813), *Guy Mannering* and *The Slave* (1816), *Maid Marian* (1822) and *Clari* (1823), introducing the air of "Home, Sweet Home." In 1825 Bishop was induced by Elliston to transfer his services from Covent Garden to the rival house in Drury Lane, for which he wrote the opera of *Aladdin*, intended to compete with Weber's *Oberon*, commissioned by the other house. The result was a failure, and with *Aladdin* (1826) Bishop's career as an operatic composer may be said to have closed. On the formation of the Philharmonic Society in 1813 Bishop was appointed one of the directors. In 1830 he was appointed musical director at Vauxhall; during this period he produced his popular song, "My Pretty Jane," which Sims Reeves made world famous. In 1841 he was appointed Reid professor of music in the University of Edinburgh, but resigned in 1843. He was knighted in 1842, being the first musician who ever received that honour. In 1848 he succeeded Dr. Crotch in the chair of music at Oxford. He died on April 30, 1855. Bishop was twice married: to Miss Lyon and Miss Anne Rivière, both of whom were singers. His name lives in connection with his numerous glees, songs and smaller compositions.

See Richard Northcott, *The Life of Sir Henry R. Bishop* (1920).

BISHOP, ISABELLA (1831–1904). English traveller and author, daughter of the Rev. Edward Bird, rector of Tattenhall, Cheshire, was born at Boroughbridge hall, Yorkshire, on Oct. 15 1831. Isabella Bird began to travel when she was 22. Her first book, *The Englishwoman in America* (1856), consisted of her correspondence during a visit to Canada undertaken for her health. But her reputation was made by the records of her extensive travels in Asia: *Unbeaten Tracks in Japan* (1880), *Journeys in Persia and Kurdistan* (1891), *Among the Tibetans* (1894), *Korea and her Neighbours* (1898), *The Yangtze Valley and Beyond* (1899), *Chinese Pictures* (1900). She married in 1881 Dr. John Bishop, an Edinburgh physician, and was left a widow in 1886. In 1892 she became the first lady fellow of the Royal Geographical Society, and in 1901 she rode a thousand miles in Morocco and the Atlas mountains. She died in Edinburgh on Oct. 7 1904.

See Anna M. Stoddart, *The Life of Isabella Bird* (1906).

BISHOP, in certain branches of the Christian Church, an ecclesiastic consecrated or set apart to perform certain spiritual functions and to exercise oversight over the lower clergy (priests or presbyters, deacons, etc.). The title is derived from the Greek ἐπίσκοπος, Latin *episcopus*, meaning "overseer." In the Catholic Church bishops take rank at the head of the sacerdotal hierarchy and have certain spiritual powers peculiar to their office, but opinion has long been divided as to whether they constitute a separate order or form merely a higher degree of the order of priests.

Roman Catholic.—In the Roman Catholic Church the bishop belongs to the highest order of the hierarchy and, in this respect, is the peer even of the pope, who addresses him as "venerable brother." By the decree of the Council of Trent he must be 30 years of age, of legitimate birth, and of approved learning and virtue. The method of his selection varies in different countries. In some countries, as formerly in France under the Concordat, the head of the state has the right of nomination. In others the bishop is elected by the cathedral chapter (as in Württemberg), or by the clergy of the diocese (as in Ireland). In others, as in Great Britain, the United States of America, and Belgium, the pope selects one out of a list submitted by the chapter. In all cases the nomination or election is subject to confirmation by the Holy See. Before this is granted the candidate is submitted to a double examination as to his fitness, first by a papal delegate at his place of residence and afterwards by the Roman Congregation of Cardinals assigned for this purpose. In the event of both processes proving satisfactory, the bishop-elect is confirmed, preconized, and allowed to exercise the rights of jurisdiction in his

see. He cannot, however, exercise the functions proper to the episcopal order until his consecration. The bishop is consecrated, after taking the oath of fidelity to the Holy See and subscribing the profession of faith, by a bishop appointed by the pope for the purpose, assisted by at least two other bishops or prelates, the main features of the act being the laying on of hands, the anointing with oil, and the delivery of the pastoral staff and other symbols of the office. Besides the full functions of the presbyterate, or priesthood, bishops have the sole right (1) to confer holy orders, (2) to administer confirmation, (3) to prepare the holy oil, or

AFTER A WOODCUT IN "FARLUNDI MODI," 1588

A BISHOP OF THE 16TH CENTURY, IN HIS ROBES AND SEATED ON HIS THRONE

chrism, (4) to consecrate sacred places or utensils (churches, churchyards, altars, etc.), (5) to give the benediction to abbots and abbesses, (6) to anoint kings. The powers, belonging to their order, are in general claimed by all bishops, whether Oriental or Anglican, belonging to churches which have retained the Catholic tradition in this respect. In the matter of their rights of jurisdiction, however, Roman Catholic bishops differ from others in their peculiar responsibility to the Holy See. Some of their powers of legislation and administration they possess in virtue of their position as diocesan bishops, others they enjoy under special faculties granted by the Holy See; but all bishops are bound,

by an oath taken at the time of their consecration, to go to Rome at fixed intervals to report on the state of their dioceses. The Roman bishop ranks immediately after the cardinals. In England he is styled "right reverend" and addressed as "my lord bishop." The insignia (*pontificalia* or pontificals) of the Roman Catholic bishop are (1) a ring with a jewel, symbolizing fidelity to the Church, (2) the pastoral staff, (3) the pectoral cross, (4) the vestments, consisting of the caligae (stockings and sandals), the tunicle, and purple gloves, (5) the mitre, (6) the throne (*cathedra*) on the gospel side of the choir in the cathedral church.

Anglican.—The spiritual function and character of the Anglican bishops, allowing for doctrinal changes effected at the Reformation, are similar to those of the Roman. They alone can administer the rite of confirmation, ordain priests and deacons, and exercise a certain dispensing power. In the established Church of England the appointment of bishops is vested effectively in the crown, though the old form of election by the cathedral chapter is retained. They must be learned presbyters at least 30 years of age, born in lawful wedlock, and of good life and behaviour. The mode of appointment is regulated by 25 Henry VIII. c. 20, re-enacted in I. Elizabeth c. I. (Act of Supremacy, 1559). On a vacancy occurring, the dean and chapter notify the king thereof in chancery and pray leave to make election. A licence under the Great Seal to proceed to the election of a bishop, known as the *congé d'élire*, together with a letter missive containing the name of the king's nominee, is thereupon sent to the dean and chapter, who are bound under the penalties of *Praemunire* to proceed within 12 days to the election of the person named in it. In the event of their refusing obedience or neglecting to elect, the bishop may be appointed by letters patent under the Great Seal without the form of election. Upon the election being reported to the crown, a mandate issues from the crown to the archbishop and metropolitan requesting him and commanding him to confirm the election and to invest and consecrate the bishop-elect. Thereupon the archbishop issues a commission to his vicar-general to examine formally the process of the election of the bishop, to supply by his authority all defects in matters of form, and to administer to the bishop-elect the oaths of allegiance, of supremacy, and of canonical obedience (see CONFIRMATION OF BISHOPS). In the disestablished and daughter Churches the election is by the synod

of the Church, as in Ireland, or by a diocesan convention, as in the United States of America.

In the Church of England the consecration of a bishop is usually carried out by an archbishop, who is assisted by two or more bishops. The essential "form" of the consecration is in the simultaneous "laying on of hands" by the consecrating prelates. After this the new bishop, who has so far been vested only in a rochet (*q.v.*) retires and puts on the rest of the episcopal habit, viz., the chimere (*q.v.*). After consecration the bishop is competent to exercise all the spiritual functions of his office; but a bishopric in the Established Church, being a barony, is under the guardianship of the crown during a vacancy, and has to be conferred afresh on each new holder. A bishop, then, cannot enter into the enjoyment of the temporalities of his see, including his rights of presentation to benefices, before doing homage to the king. This is done in the ancient feudal form, surviving elsewhere only in the conferring of the M.A. degree at Cambridge. The bishop kneels before the king, places his hands between his, and recites an oath of temporal allegiance; he then kisses hands.

Besides the functions exercised in virtue of their order, bishops are also empowered by law to exercise a certain jurisdiction over all consecrated places and over all ordained persons. This jurisdiction they exercise for the most part through their consistorial courts, or through commissioners appointed under the Church Discipline Act of 1840. By the Clergy Discipline Act of 1892 it was decreed that the trial of clerks accused of unfitness to exercise the cure of souls should be before the consistory court with five assessors. Under the Public Worship Regulation Act of 1874, which gave to churchwardens and aggrieved parishioners the right to institute proceedings against the clergy for breaches of the law in the conduct of divine service, a discretionary right was reserved to the bishop to stay proceedings in accordance with their opinion of the case.

The bishops also exercise a certain jurisdiction over marriages, inasmuch as they have by the canons of the Church of England a power of dispensing with the proclamation of banns before marriage. These dispensations are termed marriage licences, and their legal validity is recognized by the Marriage Act of 1823.

The bishops are still authorized by law to dedicate and set apart buildings for the solemnization of divine service and grounds for the performance of burials, according to the rites and ceremonies of the Church of England; and such buildings and grounds, after they have been duly consecrated according to law, cannot be diverted to any secular purpose except under the authority of an act of parliament.

The bishops of England have also jurisdiction to examine clerks who may be presented to benefices within their respective dioceses, and they are bound in each case by the 95th canon of 1604 to inquire and inform themselves of the sufficiency of each clerk within 28 days, after which time, if they have not rejected him as insufficiently qualified, they are bound to institute him or to license him, as the case may be, to the benefice, and thereupon to send their mandate to the archdeacon to induct him into the temporalities of the benefice. (*See* BENEFICE.)

As spiritual peers, bishops of the Church of England have (subject to the limitations stated below) seats in the House of Lords. The question whether a bishop of the Church of England, being a lord of parliament, could resign his seat in the Upper House was definitely settled in 1860 by the Bishops' Resignation Act. It provided that, on any bishop desiring to retire on account of age or incapacity, the sovereign should be empowered to declare the see void by an order in council, the retiring bishop or archbishop to be secured the use of the episcopal residence for life and a pension of one-third of the revenues of the see, or £2,000, whichever sum should prove the larger.

In view of the increase of the episcopate and the objection to the consequent increase of the spiritual peers in the Upper House, it was enacted by the Bishops' Act of 1878 that only the archbishops and the bishops of London, Winchester and Durham should be always entitled to writs summoning them to the House of Lords. The rest of the 25 seats are filled up, as a vacancy occurs, according to seniority of consecration.

Bishops of the Church of England rank in order of precedence immediately above barons. They may marry, but their wives as such enjoy no title or precedence. Bishops are addressed as "Right Reverend" and have legally the style of "Lord," which, as in the case of Roman Catholic bishops in England, is extended to all, whether suffragans or holders of colonial bishoprics, by courtesy.

The insignia of the Anglican bishop are the rochet and the chimere, and the episcopal throne on the gospel side of the chancel of the cathedral church. The use of the mitre, pastoral staff, and pectoral cross has, however, been very commonly, though not universally, revived; and, in some cases, the interpretation put upon the "Ornaments rubric" by the modern "Anglo-Catholic" school has led to a more complete revival of the pre-Reformation vestments.

Orthodox Eastern.—In the Orthodox Church of the East and the various communions springing from it the spiritual powers conceived as residing in the bishop are the same as in the Western Church. Among his qualifications the most peculiar is that he must be unmarried, which, since the secular priests are compelled to marry, entails his belonging to the "black clergy" or monks. The insignia of an oriental bishop, with considerable variation in form, are essentially the same as those of the Catholic West.

Subordinate Bishops.—Besides bishops presiding over definite sees, there have been from time immemorial in the Christian Church bishops holding their jurisdiction in subordination to the bishop of the diocese. Bishops *in partibus infidelium* (in the parts of the infidels) were originally those who had been expelled from their sees by the pagans, and, while retaining their titles, were appointed to assist diocesan bishops in their work. In later times the custom arose of consecrating bishops for this purpose, or merely as an honorary distinction, with a title derived from some place once included within but then beyond the bounds of Christendom. The custom is still followed, but the words *in partibus infidelium* have been dropped. *Coadjutor bishops* are appointed to assist the bishop of the diocese when incapacitated from fulfilling his functions alone. Coadjutors in the early church were appointed with a view to their succeeding to the see; but this, though common in practice, is no longer the rule. *Suffragan bishops* are those appointed to assist diocesan bishops in their pontifical functions. In the Roman Church the appointment of the suffragan rests with the pope, on the petition of the bishop. In the Church of England the status of suffragan bishops was regulated by the Act 26 Henry VIII. c. 14. Under this statute, which, after long remaining inoperative, was amended and again put into force by the Suffragans' Nomination Act of 1888, every archbishop and bishop may name two spiritual persons for the crown to give to one of them the title, name, style, and dignity of a bishop of any one of 26 sees enumerated in the statute, as the crown may think convenient. The crown, having made choice of one of such persons, is empowered to present him by letters patent under the Great Seal to the metropolitan, requiring him to consecrate him.

Lutheran Churches.—The title of bishop survived the Reformation in certain of the Lutheran churches of the Continent, in Denmark, Norway, Finland, Sweden, and Transylvania; it was temporarily restored in Prussia in 1701 for the coronation of King Frederick I., again between 1816 and 1840 by Frederick William III., and in Nassau in 1818. In these latter cases, however, the title bishop is equivalent to that of "superintendent," the form most generally employed. The Lutheran bishops, as a rule, do not possess or claim unbroken "apostolic succession"; those of Finland and Sweden are, however, an exception. The Lutheran bishops of Transylvania used to sit, with the Roman and Orthodox bishops, in the Hungarian Upper House. In some cases the secularization of episcopal principalities at the Reformation led to the survival of the title of bishop as a purely secular distinction. Thus the see of Osnabrück (Osnaburgh) was occupied, from the peace of Westphalia to 1802, alternately by a Catholic and Protestant prince. From 1762 to 1802 it was held by Frederick, duke of York, the last prince-bishop. Similarly, the bishopric of Schwerin survived as a Protestant prince-bishopric until 1648, when it was finally secularized and annexed to Mecklenburg, and the see of

Lübeck was held by Protestant "bishops" from 1530 till its annexation to Oldenburg in 1803.¹

In other Protestant communities, e.g., the Moravians and the Methodist Episcopal Church, the office and title of bishop have survived or been created. Their functions and status will be found described in the accounts of the several churches.

"Bischof" (the author rather arbitrarily classes Anglican with Lutheran bishops as not bishops in any proper sense at all); Phillimore's *Ecclesiastical Law*; the articles ORDER, HOLY; VESTMENTS; ECCLESIASTICAL JURISDICTION; EPISCOPACY.

BISHOP AUCKLAND, urban district, Durham, England, 11 m. S.S.W. of the city of Durham, the junction of several L.N.E.R. branch lines. Pop. (1921) 14,290. It is situated on high ground near the confluence of Wear and Gaunless. The parish church at Auckland St. Andrews is Early English. The fine palace of the bishops of Durham stands at the north-east end of the town; its site was first chosen by Bishop Anthony Beck, in the time of Edward I., and it is surrounded by a park of 800 acres. On the Wear 1½ m. above Bishop Auckland there is a small, probably 7th century church at Escomb, massively built and tapering upward; some stones are from a Roman building, one bearing an inscription. These, no doubt, came from Binstchester, a short distance up stream, where remains of a Roman fort (*Vinovia*) are traceable. It guarded the great Roman north road from York to Hadrian's Wall. Bishop Auckland men are employed in the neighbouring collieries and ironworks.

BISHOP'S CASTLE, municipal borough, Shropshire, England, situated on a steep hillside above an important lowland route from south Shropshire into Wales (see MONTGOMERYSHIRE). Pop. (1921) 1,267. This historic road from Ludlow past Stokesay was controlled by the castle of the bishops of Hereford, placed where the gap between the mountain line of Longmynd and Stiperstones and that of the Clun Forest narrows at the watershed between the rivers Camlad and Onny. The position is said to have been held by the bishops from the 8th century, and the castle was built by them between 1085 and 1154 to guard the route. By the 13th century a town had sprung up round the castle walls, and the historic "Road of the Castles" saw movements of many kinds. Richard II. gave the town a market every Wednesday and a fair on Nov. 2, and two days following. Although it was evidently a borough by the 13th century it has no charter earlier than the incorporation charter granted by Elizabeth in 1572. The estates of the bishops appropriated by Queen Elizabeth amounted to 18,000 acres. Only slight fragments of the castle remain. The church, with the exception of the tower, was rebuilt in 1860. There are important fairs for the sale of the cattle and sheep bred in the valleys of the Onny, Camlad and Clun tributaries. The coach-road into Wales under the Kerry Hills has been replaced by a modern road avoiding the steep slopes through the town; and Bishop's Castle suffers in consequence. There is a branch railway from Craven Arms.

The town is governed by a mayor, four aldermen, and 12 councillors. Area 1,867 acres. It was represented until 1832, but now forms, with the boroughs of Ludlow and Bridgnorth, etc., part of the Ludlow parliamentary division of Shropshire.

BISHOP STORTFORD, urban district, east Hertfordshire, England; 30½ m. N.N.E. of London by the L.N.E. railway. Population (1921) 8,858. It lies on the river Stort, close to the county boundary with Essex, and has water communication with London through the Lea and Stort navigation. Before the Conquest the manor of Bishop Stortford is said to have belonged to Eddeva the Fair, wife of Harold, who sold it to the bishop of London. It was taken by William the Conqueror, who restored it and with it gave the bishop a small castle called Waytemore, of which there are scanty remains. The dungeon of this castle, called "Bishop's Hole" or "Bishop's Prison," was used as an ecclesiastical

¹The title prince-bishop, attached in Austria to the sees of Laibach, Seckau, Gurk, Brixen, Trent, and Lavant, and in Prussia to that of Breslau, no longer implies any secular jurisdiction but is merely a title of honour recognized by the state, owing either to the importance of the sees or for reasons purely historical.

prison until the 16th century. The town possesses no early incorporation charters; but it is mentioned as a borough in 1311, in which year the burgesses returned two members to parliament. The privileges were allowed to lapse after the 14th century. The church of St. Michael, standing high above the valley, is a Perpendicular building with western tower and spire. The high school, formerly the grammar school, was founded in the time of Queen Elizabeth. There are a Nonconformist grammar school, a diocesan training college for women, and other educational establishments. The industries include brewing and malting, coach building and metal working, and there are important horse and cattle markets.

BISHOPS WARS, the name given in English history to the two brief campaigns between Charles I. and the Scots in 1639 and 1640, caused by Charles' endeavour to enforce Anglican observances in the Scottish Church, and by the determination of the Scots to abolish episcopacy. The Bishops Wars are chiefly important as the final embarrassment which forced Charles at last to summon parliament—the Long Parliament—and so to precipitate the Great Rebellion.

BISKRA, a town of Algeria, *arrondissement* of Batna, department of Constantine, 150 m. S.W. of the city of Constantine and connected with it and with Philippeville by rail, the rail-head for the desert. It lies in the Sahara 360 ft. above the sea at the exit from the gorges of El-Kantara on the right bank of the Wad Biskra, nearly dry for many months but a mighty torrent after one or two days' rain in winter. Five or six villages of the usual Saharan type are scattered through an oasis 3 m. in length by less than 1 m. broad, and separated by huge gardens full of palm and olive trees. The houses are built of hardened mud, with doors and roof of palm wood. The foreign settlement is on the north of the oasis. The main street is lined with European houses, the whole in the style of a typical French winter resort. East of the public garden is Fort St. Germain, named after an officer killed in the insurrection of the Zaatcha in 1849, in which the whole of the civil population took refuge during the rebellion of 1871. It contains barracks, hospital and government offices and commands the water supply. To the south-east lies the Villa Landon with magnificent gardens filled with tropical plants. The population (1926) of the chief settlement was 9,403, of the whole oasis 16,477.

ALGERIAN CAVALIER ON THE DESERT NEAR BISKRA

His head-dress is composed of a bunch of ostrich feathers topping the conventional turban, and a white silk handkerchief serves as mask.

The delightful climate with genial temperature and clear skies has made Biskra a famous winter resort, and while in summer the thermometer often registers 110° in the shade, and 90° at night, the pure dryness of the air in this practically rainless region makes the heat endurable. The rainfall is not above 7 inches. High cold winds in winter cause temperatures as low as 36°, but the main reading, on an average of ten years, is 73°.

In the oasis are some 200,000 fruit trees, of which about 150,000 are date-palms, the rest being olives, pomegranates and apricots. In the centre of the oasis is the old kasbah or citadel. In 1844 the duc d'Aumale occupied this fort, and here, on the night of May 12 of that year, the French garrison was massacred by Arabs. In the fort are a few fragments of Roman work—all that remains of the Roman post *Ad Piscinam* (Thermal establishment of Hamman Sahaline).

Biskra is the capital of the Ziban (plural of Zab), of mixed Berber and Arab origin, whose villages extend from the southern Aures to the Shat Melrir. These villages, in oases, nestle in groves of date-palms and fruit trees and waving fields of barley;

the most interesting is Sidi Okba, 12 m. south-east of Biskra, built of houses of one storey made of sun-dried bricks. In the north-west corner of the mosque is the tomb of Sidi Okba, the leader of the Arabs who in the 1st century of the Hegira conquered Africa for Islam from Egypt to Tangier. Sidi Okba was killed by the Berbers near this place in A.D. 682. On his tomb is the inscription in Cufic characters, "This is the tomb of Okba, son of Nafi. May God have mercy upon him." No older Arabic inscription is known to exist in Africa.

BISKUPITZ, a satellite town 5m. W. of Beuthen, in the Prussian province of Upper Silesia. Pop. (1925) 17,225. In the partition of Upper Silesia in 1921 it was retained, with Beuthen, by Germany.

BISLEY, village, Surrey, England, 3½ m. N.W. of Woking and 29 m. from London. Pop. of parish (1921) 955. The ranges of the National Rifle Association were transferred from Wimbledon here in 1890. (*See RIFLE.*)

BISMARCK, OTTO, PRINCE VON (1815–1898), was born on April 1, 1815, at Schönhausen, an estate belonging to his father, Ferdinand von Bismarck, a retired captain of the Prussian army. The family had been established in the Mark of Brandenburg for many centuries, and Bismarck's own appearance, habits and methods of thought always betrayed his origin from the country gentry. His mother belonged to a middle-class family of the name of Mencken, which had given the world a number of men of learning in the 17th and 18th centuries, and had more recently entered the higher classes of Prussian officialdom.

Early Years.—Bismarck passed the first years of his life in the country in Pomerania, where his father also possessed some estates. He then went to a school in Berlin, where he also attended the gymnasium. At 17 years of age he went to Göttingen university to study law, and his parents intended him for an official career, while his elder brother, Bernhard, was to succeed to the family estates. He completed his studies in Berlin, where he passed his first examination in law, and worked on the judicial side in the Government offices at Aachen and Potsdam. The work of a civil servant, however, gave him no real satisfaction. As the financial circumstances of his family had changed for the worse, and the proper management of the estates seemed to require further help, in view of his father's increasing age, he resigned from the civil service, and took over the management of the Kniephof estate in Pomerania. His letter defending this decision is the first record of his way of thinking that we possess. The document shows that his principal motive was the revolt of his innate love of independence, characteristic of the country gentleman, against the calling of a civil servant, with its necessary obedience to superiors and subordination of self to a whole, functioning independently of his own will. He needed a field for independent activity, in which he could exercise his powers as he himself thought best. He soon adapted himself to his new tasks, and by ceaseless labour was able in a few years to restore the somewhat neglected estate to a flourishing condition. He did not, however, relax his attention to the things of the mind during these years of quiet country life. His astonishing knowledge of German and foreign literature and history dates chiefly from this period. Travels in England and France helped to enlarge his mental horizon.

The most important development was, however, the revolution in his whole philosophy of life that took place during these years. Under the influence of his masters, and partly also, no doubt, of his mother, he had wholly lost his belief in the doctrines of Christianity, but his attempts to gain a new philosophy of life by study of the philosophers of the day, Hegel, Strauss and Feuerbach, had been fruitless. The mutual contradictions of philosophy confused his mind, the bent of which was positive and pragmatic; he required firm principles which should serve him as a guide for his actions. His studies finally convinced him that the mind of man is not able to reach positive conclusions on the ultimate (and supreme) problems of human life. While in this mood he became one of a circle of deeply religious country gentlemen, which centred round the person and the house of von Thadden at Trieglaff. Puritans at heart, they attempted to base

their lives on the principles of Christianity, held divine service for themselves in their own homes, and looked on the official Church as far too lukewarm and indifferent. Although at first inclined to mock at the tone current in this circle, Bismarck soon came to feel that these men had something which he himself lacked—inner peace and a profound sense of communion with eternal truth—and could, with their eyes fixed on eternity, endure with a light heart the changes and chances of this life. Bismarck was most deeply struck by this attitude of mind on the sudden death of von Thadden's daughter, who had married his best friend, Moritz von Blankenburg, and had also exercised a powerful influence over himself. The almost cheerful resignation with which her relations bore what they felt to be only a brief separation from the deceased filled him with admiration, and almost with envy. Gradually he began to adapt himself to their ideas, especially as he had himself conceived a warm affection for a young lady of this circle, Johanna von Puttkamer, and could not hope to win her hand unless her father and relations became convinced of his adherence to their views. It is certain that Bismarck was at heart never altogether one with these Pomeranian pietists. Religion was never so wholly a determining force for all his actions and thoughts as it was for them. It is certain, however, that what led him back to the fundamental principles of Christianity was not merely interest, but inner conviction. Christianity henceforward seemed to him the only stable and certain thing in the welter of human opinions. This fact had its importance for his career, since it was only this change that brought him into complete spiritual contact with the social class to which he belonged by birth, and with which he certainly felt the fullest sympathy at heart.

Meanwhile Bismarck's father had died, and he had moved to his birthplace, Schönhausen, near Stendal. Here in 1847 he married Johanna von Puttkamer, and here he came for the first time into close contact with that political life which was to absorb him more and more.

In the summer of 1847 the *Vereinigte Landtag*, the first general parliamentary assembly ever known in Prussia, sat in Berlin. Bismarck attended its sittings as deputy for the representative of his district, who was ill. In his speeches before this body he championed the Christian character of the State and monarchy by divine right, and thus attracted the attention of King Frederick William IV. and his confidential advisers, the so-called "Camarilla," the most important members of which were the two brothers von Gerlach. When the revolution which was destined to end absolutism in Prussia as elsewhere broke out in the spring of 1848, Bismarck hurried back to Berlin and in vain endeavoured to urge the king to vigorous counter-measures. It is easy to understand why Bismarck with his strong Conservative views, was not elected either for the Prussian national assembly or for the German parliament at Frankfurt-am-Main. He threw himself with the more energy into founding a well-organized Conservative party, and was one of the most indefatigable contributors to its first organ in the press, the *Kreuzzeitung*. It was only after the dissolution of the Prussian national assembly and the grant of a constitution and a new franchise by the king that Bismarck was elected to the Prussian second chamber. Here he again advocated the Christian State, corporate organization of industry and the maintenance of the patrimonial rights of the nobles in the rural districts. His most influential speech was in the debate of April 1849 on the acceptance or rejection of the German imperial crown, which had been offered by the Frankfurt parliament to the Prussian king. To accept would have seemed to him a capitulation before the revolution, and at the same time a subordination of Prussia to an outside power; he opposed it on both grounds, and was delighted when Frederick William refused the crown. On later occasions, he again championed the independence of Prussia, arguing that the Prussian eagle would only be able to cover Germany with its pinions from Memel to the Donnersberg if it had free and unhampered use of them. When von Radwitz's attempt to unite the German states, excluding Austria, into a federation under Prussian leadership led to the verge of war with Austria, Bismarck, in his famous "Olmütz speech" of Dec.

1850, pleaded for the preservation of peace, because he believed that such a struggle would strengthen Liberalism, and because he did not think it would, at any rate at the moment, advance the interests of Prussia. The king, who at the bottom of his heart agreed with Bismarck, now resolved to offer him a post where he could give his abilities full scope in the service of the State, and appointed him Prussian envoy at the Federal diet in Frankfurt-am-Main (1851).

Bismarck in Frankfurt.—The diet, which was composed of representatives of all German governments, had been, since 1815, the only institution which gave expression, though in very imperfect fashion, to the sentiment of national homogeneity among these States. Bismarck had here an unrivalled opportunity of acquainting himself with the policy of the German governments and the personalities of the leading statesmen. The seven years which he spent in Frankfurt (1851–58) were his real schooling in diplomacy and statesmanship. When he went there he was still convinced that German interests would be best served if Prussia and Austria were associated in the conduct of affairs, always with the proviso that Austria should honestly recognize Prussia as an equal. His experiences in Frankfurt soon, however, taught him that he could reckon on no such assumption; that Austria, on the contrary, was aiming of set purpose to reduce Prussia's influence in Germany. His Prussian pride rebelled against such an attempt, and he was at pains to thwart it by every means in his power and to establish closer contact with Bavaria and the other smaller states. During the Crimean War (1854–56) he did all in his power to prevent German forces being used to further Austria's interests in the East. He warned his Government urgently not to chain the fine, sea-worthy frigate Prussia to the old, worm-eaten flagship Austria. Co-operation with Austria was desirable only if the latter guaranteed a substantial return and recognized Prussia's equal standing in German affairs. As this could not be expected, they must accustom themselves to looking on Austria as an enemy. As early as April 1856 he said in a dispatch: "German dualism has regulated its internal relations at intervals for a thousand years, and, since Charles V., regularly once a century by a thorough internal war, and our century too will find no other means than this to set the clock of development to the correct time. . . . I only want to express my conviction that before very long we shall have to fight for our lives against Austria, that it is not in our power to escape this, because the progress of events in Germany has no other issue." Both Prussia's State interests and his sentiments as a German thus led Bismarck to take a course directly opposite to that which he had recommended even in 1850. In other respects also he had thoroughly revised his ideas during his stay in Frankfurt, and had moved in spirit ever further from the views of Frederick William IV. and the Camarilla.

Bismarck had formerly been opposed to parliamentary institutions in any form. Gradually, however, he became convinced that a modern state could no longer exist without them. In the interests of foreign policy also it seemed to him important that a channel should exist through which popular feeling could express itself, as this would afford a firmer support, abroad as well as at home, to a sensible policy adapted to the real interests of the country. He recommended to his Government strict observance of the constitution, a more liberal treatment of the press, and the maintenance of contact with popular opinion, especially in economic questions.

Most characteristic of all was Bismarck's rupture with the ideas of the romantic politicians who had controlled affairs under Frederick William IV. The king himself and the brothers Gerlach saw in the world only the great conflict between belief and unbelief, between monarchical authority by divine right and liberal and democratic demands based on human caprice and presumption. They were convinced that those powers whose form of state was based on similar principles should also hold together in foreign politics. They looked on Russia, Austria and Prussia as the main champions of authority, on France as the champion of revolution, while on England they hesitated to pronounce judgment. They therefore held that Russia and Austria were Prussia's natural

allies, France her natural enemy. Bismarck preached with increasing emphasis the contrary principle that no state should be swayed by anything but its considered interest, and that its friendship with or hostility to another state must be judged by the sole consideration whether it would be advantageous or disadvantageous to itself. "In politics," he said, "no one does anything for his neighbour unless he finds it to his own interest."

These years in Frankfurt were of extraordinary value for Bismarck's political development. He did not, of course, acquire here the qualities which made him a great statesman; they were innate in him; but here he harvested the experience which is as necessary to a statesman as to a man of any other profession. It was here that he first freed himself from the political dogmatism that naturally clung to him so long as he remained simply a Conservative party man, and learned to judge facts without prejudice and solely with an eye to the interest of the State. The inner transformation which took place in him here was known, indeed, to few, and the wider public still saw in him only a convinced supporter of the extreme Conservative party, of the *Kreuzzeitung* group.

Ambassador in St. Petersburg (Leningrad) and Paris.—

In 1858 the health of Frederick William IV. was so seriously affected as to prohibit him from further conduct of affairs and his brother William took his place as prince regent, and in 1861 as king. In both domestic and foreign policy his principles differed widely from his brother's; in particular he wished to establish good relations with the Liberals, who were in the majority in the Prussian House of Deputies, and to govern impartially. Sharing the general view of Bismarck as a Conservative party man, he thought it better to remove him from Frankfurt and replace him by someone of more liberal tendencies. He therefore sent him to St. Petersburg as Prussian ambassador. Bismarck himself relished this turn in his fortunes but little. He looked on it as a sign of mistrust, and declared that he had been sent into exile on the Neva. Yet this was a most important stage in his development. He left the confined circle of German conditions and came to one of the great European courts, in which he could observe the policy of the great Powers much more closely and directly than had been possible in Frankfurt. His new experience did not alter his political convictions. During the war of 1859 between Austria, Sardinia and France, Bismarck again urged most strongly that no support should be given to Austria without a return. He remained in St. Petersburg for more than three years; then events occurred which brought about his translation into a wider sphere of action.

King William had become involved in a violent conflict with parliament. It had arisen out of the proposed expansion and reorganization of the army. The king had proposed to remove the limitations on the general three-years' service and to link the *Landwehr* (*q.v.*) more closely with the standing army. The Liberal majority of the House of Deputies opposed this vigorously, not only on the score of the heavy cost, but also from fear that the democratic character of the *Landwehr* might be impaired. In the course of the conflict the deputies called on the king to take men who possessed the confidence of the house into his ministry, and on his refusing, proceeded to throw out the budget. The struggle grew ever more acute. The army question developed into a constitutional one, and the king saw himself faced with the alternatives of giving in to the demands of the House of Deputies, or of carrying on the government without a budget passed by the peoples' representatives. A dissolution of the house only resulted in increasing the Liberal majority, and the decision could no longer be delayed. The king's conscience was acutely tormented; against the oath which he had sworn to the constitution, stood his conviction of the sovereign's right to choose his ministers himself, and of the necessity of the proposed reforms. For a time he even thought of abdicating in favour of his son. The minister of war, von Roon, was chiefly responsible for persuading him to abandon this idea and carry the struggle with the parliament through to the end. It was Roon again who repeatedly urged on the king that Bismarck was the man who could give him the best support in this struggle. As early as the spring of 1862 the idea of making

Bismarck head of the ministry was mooted. The king could not, however, make up his mind to this, and appointed him ambassador in Paris.

During his stay in Paris in the summer of 1862 Bismarck made himself better acquainted with conditions in France, and in particular with the personality of the emperor Napoleon III.—a matter of great importance for his later judgments on French policy. In September Roon at last won the king's consent to the appointment of Bismarck as Minister-President. In his decisive conversation with the king on Sept. 22, Bismarck declared himself prepared to carry through the struggle with parliament, but refused to lay down a definite programme, on the ground that events could not be foreseen.

Character and Intentions on Assumption of Office.—

Bismarck was now 47 years of age, and in the prime of his power and faculties. His tall, imposing figure, his piercing light-grey eyes, his easy and cultivated bearing revealed an extraordinary personality. His sure gift of observation, his swiftness to seize a situation and his unfailing decision were exceptional qualifications for politics. His cultivated mind, his mastery of language, his ready wit and dry humour were characteristics which raised him, as a man, far above the level of the ordinary professional politician. The broad lines of his political programme had already been determined. The basic idea of his creed was his unquenchable belief in Prussia's destiny to unite Germany under her leadership. Foreign diplomats said at this time that this was his fixed idea. Bismarck had always felt himself a German; but his inspiration derived neither from the sentimental idealism of the Romantics, nor the Liberals' and the Democrats' desire for a common domestic political life and a more powerful common representation of the people. He was first and foremost determined that Germany, by achieving a closer political consolidation, should once more become mistress of her own destinies, free herself from the foreign political influences which had played so great a part in her history ever since the Thirty Years' War, and secure for herself a respected and equal position beside the other great nations of the world. He was convinced that the starting-point of such an organization of the national forces of Germany must be Prussia, and that every increase in the power of Prussia must benefit the whole of Germany.

Like the Liberals, he considered a measure of internal unification necessary for united Germany, but thought it should be less extensive than they demanded. He proposed to leave to the individual German States, as they had been moulded by the course of history, as much independence as was compatible with the indispensable unified control. He too, indeed, desired a national representative body; but only as a legislative and advisory organ, while the real conduct of policy was to remain in the hands of the Government. He knew that his object could only be attained through a conflict with Austria, and wished to maintain good relations with France and Russia, to ensure their not attacking Prussia in the rear during this necessarily severe struggle. At first he also considered whether the desired union of Germany without Austria could not be achieved by successive stages, beginning with the formation of closer ties between Prussia and the northern States of Germany, and only bringing the southern States into the federation at a later date. He never considered the restoration of the absolutist system, but was determined to defend the independence of the crown, particularly in the conduct of foreign policy, by all means in his power, and not to shrink from a temporary dictatorship, should this prove necessary.

In all his decisions the supreme criterion was the interest of the State; he took no account of political theories and convictions except to consider how numerous were their adherents and consequently, how far they had to be reckoned with in the attainment of particular ends. He was no cold calculator or mere brain-machine, like Cardinal Richelieu; often enough his impulsive character led him to make statements which he would not have made in cold blood. He was a man of strong passions and emotions; he clung with deep love and devotion to his wife, his family, his home, his State and his sovereign's dynasty; but towards mankind as such he felt no profound obligation. He has often been

accused of despising humanity; he did so no more and no less than every great statesman or general prepared to use human forces and sacrifice human lives for the attainment of great ends.

His contemporaries at first were completely puzzled by his policy, because the habit of the day was to judge political facts from the standpoint of theories which were held to be immutable truths, while Bismarck cared nothing for the sanctity of theory and only employed theoretical catchwords as weapons for achieving certain ends. His respect for public opinion, and indeed for any opinion but his own, was always small; for he was aware that actions, and not beliefs or speeches, are what count in controlling a great state. It was easy, he thought, for journalists and politicians to write and make speeches on the sensible and necessary course; they had not to take the consequences if their advice led to unfortunate results, not being responsible for the actions or omissions of the Government.

Now Bismarck's supreme political quality was precisely his readiness to take responsibility. If he thought a policy right, he staked his public and private reputation on it without reservation, and never considered the possible consequences to himself of a failure. At any moment he would have been prepared to exchange the brilliant position of a minister-president for the modest but independent life of a country gentleman, if he had not been conscious that as minister he could accomplish something for his fatherland of which others were incapable, and that his true destiny lay in accomplishing it.

First Measures.—The first months of his work as minister-president were occupied in domestic politics, with the struggle against parliament—the real cause of his appointment to his post. Bismarck declared that if the House of Deputies rejected the budget, the Government had the right to continue collecting existing taxation, and to carry on the Government without a budget in legally sanctioned form; for the constitution contained no provision in the case of disagreement on the budget between the three factors (King, Upper House and House of Deputies) whose united consent was necessary for a bill to become law. He even raised the question whether an assembly elected on the three-class suffrage could be considered truly representative of the people, in view of the predominant influence exercised on its composition by the richer classes. He attempted to cow his opponents by restricting the freedom of the press and influencing elections. He was, however, unable to do away with the Liberal majority in the House of Deputies; and the conflict between the crown and parliament continued unabated for some years.

Bismarck directed his attention, however, mainly to foreign policy. If he could achieve great successes in this field, and satisfy the deepest ambition of every German patriot by uniting Germany under Prussian leadership, the position of his Government would certainly be greatly strengthened. It was even probable that popular opinion would veer round in favour of a Government which could point to such successes, and that such a change in public opinion would bring a different majority into parliament, and one which would be more amenable to compromise than the present one.

Bismarck was faced with his first important decision in Aug. 1863. The Austrian emperor had invited all German princes to assemble at Frankfurt-am-Main to debate and approve proposals of his own for a reform of the German Bund. The court at Vienna hoped to utilize the conflict between the Prussian Government and the representatives of the people and the consequent ill-feeling in Germany, where Liberal opinion was dominant, to remodel arrangements in Germany to the advantage of Austria. Austria proposed, while making apparent concessions to the Liberals, to invest the real Government of Germany in a "Directory" of five members, in which Austria, with the help of the small states with which she was closely allied, would always have commanded the majority. The plan was unacceptable to Prussia, and would not, indeed, have permanently satisfied the national requirements of the German people; for what was here proposed—an assemblage of delegates from the diets of individual states—could never have taken the place of a real German parliament, particularly if it had only an advisory character.

Bismarck prevailed on his sovereign to return a polite refusal to the invitation, on the ground that a personal conversation between the princes would be pointless unless the Governments had come to previous agreement in principle on the reforms to be effected. Bismarck knew that no resolutions of importance could be taken in Frankfurt without the co-operation of Prussia. The princes assembled in Frankfurt were equally aware of this, and sent King John of Saxony to King William to urge him not to refuse his collaboration in the work of reform. The king hesitated; it looked as though his profound sense of the community of dynastic interests would prevail. Then Bismarck threw the whole weight of his personality into the other scale; he threatened to resign if the king insisted against his advice in attending the diet of princes. After a hard struggle he carried his point, and William refused the king of Saxony's request.

This was the first time that Bismarck had been engaged in a violent personal conflict with his king, whom he genuinely loved and respected. Victory in this instance was the necessary preliminary for his later successes. Some months before, he had explained his own ambitions for Germany to the German Governments and to all the world: a closer German federation under Prussian leadership, with a parliament representative of the whole nation, parallel with the individual governments. If Austria were prevented by her close connection with Hungary, Bohemia, and other non-Germanic lands, from participating in so close a federation, she must remain outside it, and not be permitted to prevent the closer union of the rest of Germany. By thwarting the Viennese plan of reform, Bismarck cleared the way for the realization of his own proposal. Before he could set about it seriously, however, unforeseen events intervened, which proved unmistakably to what a great extent the German question was also a European question. The scene was Schleswig-Holstein, on the northern frontier of Germany.

The Schleswig-Holstein Question; War with Denmark (1864).—The preceding generation had striven in vain to solve the Schleswig-Holstein question. During the revolution of 1848 the German inhabitants of Schleswig-Holstein had attempted to free themselves from the close bond with Denmark created by the common dynasty. At the time they had been unsuccessful. By the London Protocol of 1852 the European Powers had recognized the attribution of these provinces to the Danish State. On extinction of the branch of the Oldenburg dynasty then regnant in Denmark, the Holstein-Glücksburg line, to which the succession passed under Danish law, was also to retain the government of the duchies; but Schleswig and Holstein were to be left their own administration and their own diets within the framework of the Danish State. In 1855 the king gave Denmark a constitution incompatible with these provisions; thereupon the estates of Holstein (Holstein being a member of the German Bund) appealed to the Bund for help. The king of Denmark was forced to retract the constitution as respecting Holstein, under threat of a Federal Execution; it remained, however, in force for Schleswig, which was not a member of the German Bund. The Bund, however, called on the king to issue a wholly new general constitution and one in accordance with the London Protocol. On his refusal a Federal Execution was decreed against him, in his capacity of duke of Holstein, and preparations for its enforcement were made.

At this juncture Frederick VII. of Denmark died (Nov. 15, 1863), and the regnant branch of his house became extinct in the male line. The prince of Glücksburg now assumed the government of Denmark and the duchies as Christian IX., but the inhabitants of Schleswig and Holstein maintained that the succession should pass, by old local usage, to another branch of the Oldenburg family, the Augustenburg line. Prince Frederick of Augustenburg appeared in the country and proclaimed himself duke of Schleswig-Holstein, under the title of Frederick VIII.

The situation thus created was extraordinarily difficult. Public opinion in Germany pronounced strongly in favour of the prince of Augustenburg and the complete separation of the German duchies from Denmark, but the two great German Powers were pledged by their signatures to the London Protocol to recognize the succession of Christian IX. Bismarck aimed from the first

at utilizing this opportunity to liberate Schleswig-Holstein from Danish rule. He had no intention, however, of allowing the formation of a fresh small state under the prince of Augustenburg. He wished to unite this territory, whose geographical situation between the North sea and the Baltic gave it great importance, with Prussia. He often said afterwards that the diplomatic campaign which he had to carry out here had been the hardest of his whole life.

At the beginning he stood quite alone. The majority of the population of Schleswig-Holstein wished to form a new state under the prince of Augustenburg; King William, and even more, his son, the Crown Prince Frederick William, who was a close personal friend of the prince of Augustenburg, also favoured this solution, which was mainly supported by the medium and smaller German States, the Liberal parties of every German parliament, and public opinion in Germany as a whole. Austria and the non-German Great Powers stood for the maintenance of the London Protocol with the grant of a certain measure of independence to the duchies. Russia and England, in view of their own interests in the Baltic and the North sea, were particularly anxious to prevent union between Schleswig-Holstein and Germany, while Austria desired to prevent any increase of Prussian power. The one circumstance which favoured Bismarck was the lack of unanimity among the Powers themselves.

Only one Great Power offered Bismarck its support from the first. This was France. Napoleon III. was prepared to allow Prussia to acquire Holstein and Southern Schleswig, provided that Northern Schleswig were left in entirety to Denmark. His main object was to create permanent hostility between Prussia and Austria in order to leave Prussia wholly dependent on his good will. Bismarck was, however, much too cautious to become party to such a pact; he knew that King William regarded Napoleon with the greatest suspicion, and that the emperor's hostility towards German unity was the greatest obstacle in the way of his national plans. He therefore refused this offer and determined to take another course.

To avoid having to face three adversaries simultaneously, he first sought a rapprochement with Austria, with which State he concluded a treaty to solve the Schleswig-Holstein question by joint action, beginning with an attempt to put pressure on Denmark to carry out the London Protocol in good faith. Denmark, trusting in the support of the other Great Powers, refused to make any concession. Prussia and Austria thereupon declared war on Denmark (1864). Bismarck succeeded in keeping Austria Prussia's ally until the campaign, which was no very difficult one, was ended and the danger of intervention by the European Powers was past. As soon as Denmark's defeat was assured, the allies granted her an armistice, and a European conference met in London to discuss the termination of the conflict. On Denmark's repeating her refusal to grant the duchies a wholly independent constitution and administration, the German Powers proposed the complete separation from Denmark and the establishment of an independent duchy. This suggestion, again, Denmark refused; the conference broke down and the campaign proceeded. Receiving no foreign assistance, Denmark was finally obliged to cede Schleswig-Holstein unconditionally to Austria and Prussia. The decision on the future of the duchies now lay with the two principal Germanic Powers. (See also SCHLESWIG-HOLSTEIN.)

Relations with Austria; War of 1866.—The treaty concluded between them prior to the campaign contained a clause providing that neither contracting party should take any decision on the further destinies of the duchies, if taken from Denmark, without consulting the other. Bismarck knew of course that agreement in the question would prove very difficult; but by this provision he had made certain that the question could not be settled against Prussia's wishes and interests. At first the two Powers assumed the joint administration of the duchies; but this arrangement soon gave rise to very serious difficulties. Austria had now changed her attitude, and wished to recognize the prince of Augustenburg as sovereign of Schleswig-Holstein. Bismarck, however, was determined not to allow the creation of a new small state unless the new duke entered into the closest union with

Prussia, left the army, posts and telegraphs entirely in Prussian hands and allowed Prussia to construct and garrison a canal between the North sea and the Baltic. As soon as he was convinced that Prince Frederick would not agree unconditionally to these terms, Bismarck definitely opposed his candidature. He had never recognized its validity in law. Austria's refusal to expel the prince of Augustenburg from Schleswig-Holstein and to repress the agitation which was being conducted in his favour gave rise to grave differences between herself and Prussia, which nearly led to war as early as the summer of 1865. King William's urgent desire to avoid such a war, and the uncertainty as to the attitude which Napoleon III. would adopt in such a case, led Bismarck to consent to the conclusion of the Treaty of Gastein with Austria (Aug. 14, 1865), by which, to avoid further friction, Prussia took over the sole administration of Schleswig and Austria of Holstein. As an expression of his delight that war had been avoided, the king conferred on Bismarck the rank of count.

Bismarck was well aware that the solution afforded by this agreement was only apparent. He was more firmly convinced than ever that no permanent solution could be reached either of the Schleswig-Holstein or of the German question without an armed conflict with Austria. Believing it to be inevitable, he used his utmost endeavours to ensure that the conflict should take place under the most favourable conditions for Prussia. He had to overcome his king's desire for peace, the sympathies entertained by all the Conservative elements in Prussia for Austria, the aversion of all parties from a fratricidal war between Germans; and at the same time to avoid the danger which threatened from France. Napoleon wished to utilize the coming war to establish himself in the position of mediator in Germany and if possible to advance the frontier of France to the Rhine. Bismarck knew this, and boldly decided to restrain the French emperor if possible by holding out prospects that his wishes would be fulfilled in the event of a Prussian victory, while making no definite promise; he did this in the confident expectation that if Napoleon could be kept from intervening before a decision had been reached, it would be possible, when victory was won, to adopt a very different tone towards him. The details of his policy cannot be given here. The decisive impulse in all important decisions taken in these years came not from the old king, but from Bismarck. The treaty with Italy of April 8, 1866, the object of which was to hold part of Austria's fighting forces in the south, was his work, as was the Federal reform plan which he laid before the Federal diet during the critical days, which envisaged a German parliament based on general and equal suffrage.

On Austria's attempting to convoke the Holstein diet and secure through it the recognition of the prince of Augustenburg as duke, Bismarck declared this to be a breach of the Treaty of Gastein, which provided only for a division of the administration of the duchies, and not of their sovereignty. The convocation of the diet was a sovereign prerogative which could only be exercised by Austria and Prussia jointly. This action had annulled the Treaty of Gastein; and Prussia therefore claimed that her right to have a voice in the administration of Holstein, and to station troops there was restored. Prussian troops actually entered Holstein. Austria declared this action a breach of peace of the Bund, and demanded that the diet should undertake a Federal execution against Prussia. Bismarck let the assembly know that any vote cast in favour of the Austrian motion would be regarded by him as a declaration of war against Prussia. The diet, nevertheless, accepted the Austrian resolution, in a somewhat attenuated form, by a small majority. Bismarck then declared the treaties on which the German Bund was based to be broken and the Bund dissolved. At the same time he called on the other German States to conclude a fresh treaty with Prussia on the basis of the plan of reform mentioned above.

Napoleon's Intervention. Peace of Nikolsburg (1866).—These events made war inevitable. Although the South German States, with Hanover, Hesse and Nassau, stood by Austria, the war ended, after a short campaign, in the complete defeat of Austria at the battle of Königgrätz (July 13, 1866). Napoleon now intervened, however, with an offer couched almost as a

command, to the two belligerent States to mediate for the restoration of peace. All Bismarck's diplomatic skill was required to save the fruits of his victory in this difficult hour. By accepting the offer of mediation, but consenting to an armistice only on condition that the main conditions of peace were laid down in advance, he enabled the advance of the Prussian troops on Vienna to proceed despite the French intervention. Napoleon, whose army was not ready for armed intervention, was in danger of becoming a laughing-stock before the whole world by his futile offer of mediation. To escape this situation, he agreed to Bismarck's proposal that Austria should secede from the German Bund, and that the North German States should form a North German federation under Prussian leadership, while the South German States (Bavaria, Württemberg, Baden and Southern Hesse) should remain independent. He also allowed Prussia to incorporate Schleswig-Holstein, and the chief North German States, which had taken Austria's side in the war, in her territory. The only condition he made was that the kingdom of Saxony should suffer no diminution.

This plan for a provisional reorganization of Germany did not wholly harmonize with Bismarck's ideas; yet it meant a first step on the road to their realization. He therefore carried it through in the teeth of the legitimist scruples of the king and the Conservatives, who saw in the removal of legitimate sovereign dynasties an offence against the principles of their political creed. King William wished to take only a part of each conquered state, without extinguishing any of them. The injured princes would then, however, have been members of the new federation, and would have formed, as Bismarck saw, a grave danger for its inner harmony. After a heated struggle with the king he carried through his plan for the complete incorporation of Hanover, Kurhessen, Nassau and the free city of Frankfurt, all the other States being left intact. Thus he ensured to the Prussian State a compact, unbroken territory, and prepared the way for an honest understanding and a later alliance with the surviving States. He was far-sighted enough to insist that no cession of territory should be demanded from Austria; he wished to leave open the possibility of a later reconciliation with the opponent of to-day.

After the signature of the Peace of Nikolsburg with Austria (July 26, 1866), Napoleon suddenly demanded a reward for his good offices. At first he asked for the whole of the Bavarian Palatinate and the Hessian territory on the left bank of the Rhine, including the fortress of Mainz. When Bismarck refused this demand, Napoleon asked to have at least Landau and the Saar district, with the Grand Duchy of Luxembourg; Prussia to compensate the king of the Netherlands, the actual ruler of the province, for its loss. With these demands again Bismarck could not and would not agree, since any cession of German territory to France would have been imputed to Prussia as treachery to the German cause, and would have made his task of assuming the leading rôle in the union of Germany extraordinarily difficult. Napoleon was obliged to content himself finally with Prussia's renouncing the right to keep a garrison in the fortress of Luxembourg—a right which in any case had no longer any justification in law, since the Grand Duchy of Luxembourg had seceded from the German Bund in 1866. The French demands created for a while some danger of a war with France. Bismarck utilized the occasion to persuade the South German States to conclude an offensive and defensive alliance with the North German federation, and thus to lay the foundations for the future union of North and South Germany.

Expansion of the North German Federation.—After the victorious close of the war with Austria and the foundation of the North German federation, Bismarck thought the time had come to restore peace in the domestic politics of Prussia also, and to put an end to the constitutional struggle. He prevailed on the king, despite his resistance, to bring in an Indemnity Act, asking the diet for retroactive approval of the taxation levied in the preceding years without parliamentary sanction. The elections held after the successful war had brought considerable changes in the composition of the diet. The Liberal party had split; the right wing, which had constituted itself, under the leadership of Rudolf von Bennigsen, into a separate National

Liberal group, was ready for a reconciliation with Bismarck, recognizing in him the man most likely to bring about the union of Germany. The diet accepted the Indemnity Act, thereby restoring domestic peace. Only this circumstance restored to Prussia the internal solidity necessary to enable it to become the head of the federal German State.

The extraordinary interplay of boldness and forethought, of broad calculation and wise regard for the needs and circumstances of the moment, which characterizes Bismarck's whole political career, is nowhere so evident as in his policy during 1866. If Germany emerged from this war, not indeed wholly united, but yet a nation which already held within it the nucleus of a new political form and the potentiality of further development, this is due to Bismarck's intervention at the critical moments.

The work of German unity, or Bismarck's vision of it, was, however, not yet complete. The Zollverein (*q.v.*) was, indeed, extended and renewed, and a close economic bond thus at once created between the south German States and the north. A common Customs parliament sat in Berlin, and offered the deputies from the various parts of Germany, for the first time since the days of the Frankfurt parliament, a fresh opportunity of promoting, through their common labours, the community of their interests. The competence of this assembly, was, however, strictly confined to economic questions. Even the offensive and defensive alliances, the conclusion of which has been noted above, afforded no absolute guarantee that all Germany would unite in arms in case of danger from an outside power, since the contracting States could raise the question whether the *casus foederis* had really arisen. Even during the Luxembourg crisis some of the South German statesmen had sought to weaken the interpretation of the treaties. The completion of the constitution of the North German federation in the summer of 1867, giving a preponderant influence in the government of the new federal State to its most powerful member, the king of Prussia, strengthened the opposition widely felt in the south against adherence to the federation. Added to this, Bismarck had differences of opinion and conflicts with his old party associates, the Conservatives, who could not forgive him for dethroning German princely houses and for the Indemnity Act, while he was equally at variance in many important points with his new parliamentary allies, the National Liberals. It often seemed likely that the old bitter parliamentary conflicts would be renewed in the new State. These were anxious and gloomy years for Bismarck; his work made no progress; for there was a danger that the division of Germany by the line of the Main might be permanently established and that the last result of all these battles and labour might be a sundered Germany, instead of a Germany for ever united.

Origins of the Franco-German War of 1870. The Ems Telegram.—This situation was terminated only by the great Franco-German War of 1870. It has often been said that Bismarck provoked this war of set purpose. This, however, was not the case. The real cause of the war was Napoleon's anger at the humiliation which he had undergone in the preceding years; his fear that the existence of a unified Germany, powerful both as a military and an economic factor, would make it impossible for France to gain the left bank of the Rhine and to maintain her hegemony on the continent; and finally, his fear that his own rule in France might end abruptly if he failed to achieve some solid success in foreign policy. Since 1867 he had been negotiating with Austria and Italy for an alliance against Prussia. He had not, indeed, been successful; but these endeavours are clear enough indications of the final objects of the emperor's policy. It would have been easy for Bismarck to provoke war with France as early as 1867, in connection with the Luxembourg crisis. At the time, however, he declared unequivocally that he wished to avoid it if possible. The necessary condition was, indeed, that France should abandon all further interference in German affairs, and reconcile herself to the union of Germany. As Bismarck always thought it doubtful whether the emperor would, or whether, indeed, in the state of public opinion in France, he could pursue such a policy, he was obliged always to be prepared for

war with France. When he learned of Napoleon's endeavours to bring about an alliance against Prussia, it was his duty to take advantage of every opportunity to strengthen Prussia's position against France.

Such an opportunity arose when the Spaniards, after expelling Queen Isabella, offered the crown of their country to a German prince of the Catholic cadet line of the Prussian royal house, Leopold von Hohenzollern-Sigmaringen. Bismarck knew that it would be disagreeable to Napoleon should this offer be accepted, because close understanding between Spain and Germany would force him to keep troops on the Pyrenean frontier in case of war. Yet he could not admit that Napoleon had any right to interfere in this question, and persuaded Prince Leopold to accept the Spanish offer. When this became known, before the election took place, Napoleon attempted to persuade King William to forbid the prince to accept the crown. The old king, who wished to avoid a war if possible, went to the extreme limit of possible concessions. He refused to influence the prince officially in any way, but informed him privately that he would like him to renounce his candidature. France was not, however, satisfied. She thought the moment had come to humiliate the Prussian king publicly and thus damage his position in Germany. She demanded that King William should address a letter of apology to Napoleon, and forbid the prince to renew his candidature at any later date, should he be elected by the Spaniards after all. The king, who was at that time taking a cure at Ems, rejected this demand and communicated the facts to Bismarck, who had hurried back to Berlin from his estates at Varzin, in Pomerania, on receipt of the news, at the same time empowering him to communicate his refusal to the other Powers and to the general public. Bismarck made use of this permission. He immediately published the king's telegram, omitting certain details which were unsuitable for publication. These are the facts on the strength of which he has often been accused of falsifying the famous "Ems telegram." The accusation is entirely unfounded. He was never ordered to publish the unabridged text of this telegram; the king simply authorized him to make public the facts reported therein (Napoleon's demand and his own refusal). He was left entirely free to do this in whatever form he wished, and in his published version he did not add one detail which was not in the telegram. His only intention was to show the world as clearly and definitely as possible the humiliation which Napoleon had tried to inflict on the King of Prussia, and the fact that this demand had met with a refusal. The emperor Napoleon and his advisers were thus placed in a disagreeable situation. Instead of scoring a diplomatic success, it was they who had incurred a rebuff. They thought it impossible, in the interests of French prestige, to accept this quietly, and declared war on Prussia. It is probable that Bismarck anticipated and expected this result of his action; but having reached a stage when things must end with a humiliation either for France or for Prussia, he thought it his duty to stand firm and let France make this a *casus belli* if she really desired. The French statesmen were to blame for causing such a situation to arise; had they contented themselves with Prince Leopold's withdrawal of his candidature, the affair would have ended without war, with a minor success for France. By refusing to be satisfied with this, and attempting to force King William to a step humiliating for himself, they created the situation which led to war.

Conclusion of Peace and Foundation of the German Empire (1871).—After the war had ended in victory for Germany, the French empire had collapsed and the German troops were outside Paris. Bismarck approached the difficult task of bringing about a favourable peace for Germany and at the same time ensuring that the German States, which had waged this war jointly, should now be welded together permanently in a solid political union.

The South German States had all admitted the *casus foederis* after the French declaration of war, and had placed their troops, in compliance with the treaties, under the supreme command of the king of Prussia. At that time, however, none of them, except Baden, had any intention of joining the North German

confederation. Only the overwhelming enthusiasm manifested by the entire people after the great victories of the war made the kings of Bavaria and Württemberg conscious that it would hardly be possible for them to preserve the old relationship after the end of the war. It was hard enough, for all that, to find a form of adherence satisfying to all parties. Bismarck scrupulously avoided putting any sort of pressure on the South German Governments, not wishing to expose himself to the reproach of having exploited the moment when those sovereigns had loyally placed their troops under Prussian command to rob them of their independence. He waited until the force of public opinion drove them to approach him. After the negotiations had once begun, however, he made it quite clear from the first that he could not conceive of any other possible form of union but their entry into the existing confederation. He showed himself ready, however, to allow Bavaria and Württemberg certain special privileges, particularly in matters of taxation and of a certain independent status for their troops within the imperial army. He refused Bavaria's more far-reaching demands for a share in the direction of imperial policy, but allowed the establishment of a diplomatic committee under Bavarian presidency in the imperial council. This institution, however, always remained a purely decorative one. Bismarck's guiding principle was to secure the necessary unity in political and military control, while leaving the individual States all possible liberty in other matters. After difficult negotiations, he succeeded in bringing the treaties with the South German States, which were to form the basis of the German empire, to their conclusion at Versailles, on Nov. 20, 1870. It was at his instance, too, that King Louis II of Bavaria decided, in agreement with the other princes, to ask King William to assume the title, hallowed by old German tradition, of German Emperor; the letter in which the king of Bavaria set forth this request was drafted by Bismarck. When the proclamation of the new German empire was effected in the Hall of Mirrors at Versailles on Jan. 18, 1871, and the banners of all the German States were lowered to salute the new emperor, Bismarck could truthfully say that the great object to which he had devoted the whole force of his extraordinary personality was now fully attained.

Peace had not yet been concluded with France. After the great victories of 1870, public opinion in Germany had declared with increasing insistence that the time had now come to recover Alsace and Lorraine, two provinces which had been forcibly separated from Germany in the hour of the old empire's greatest weakness. Bismarck regarded their recovery as essential in the interest of the military security of Germany's south-western frontier. He therefore insisted at the peace negotiations that France, besides paying a war indemnity of 5,000,000,000 francs, must also cede these territories. A much contested point was the cession of the fortress of Belfort, on which Bismarck finally gave way, although he could probably have gained this also. It has often been suggested that Bismarck was mistaken in requiring these territorial concessions from France, and that friendly relations between France and Germany could have been re-established more easily had the French frontiers been left intact. But setting aside the fact that these were old German districts, it seems safe to say that France's embitterment against Germany would hardly have been less had she been left in possession of them. The strongest incentive to revenge was anger at the military defeats she had incurred and the loss of her hegemony on the Continent; and this idea did not first appear after 1870; it began to show itself active in French public opinion after the events of 1866. At that time the cry was for revenge for Sadowa; later it became revenge for Sedan and Alsace-Lorraine.

The future destiny of Alsace-Lorraine also demanded fateful decisions. Bismarck rejected all suggestions for a partition of these territories among the different German states, because he feared that such a scheme might awaken the jealousy of those states which received no part of them. His idea was to keep Alsace-Lorraine the common property of all Germany, thus forging them into a fresh link of unity. They were accordingly made

a "Reichsland" (imperial province), and placed under the government of an imperial viceroy.

Foreign Policy After 1871: Alliances.—Fresh tasks awaited Bismarck after the conclusion of peace with France and the establishment of the new imperial constitution. The emperor now recognized his great services by elevating him to princely rank (March 21, 1871) and appointing him imperial chancellor. As such he was responsible for the direction of the whole of Germany's policy. He now had to secure peace abroad, and maintain the new-born German empire in the position which it had won, at the same time seeing to it that the new internal arrangements, which existed only on paper, really became vital and penetrated the national consciousness.

The recently published documents of the German foreign office have shown beyond cavil that Bismarck's principal aim in foreign policy during the next decades was the maintenance of peace. The peace of Europe was liable to be threatened from two directions; from the East or from the West. In the West France's desire to be revenged for 1870 and to recover Alsace-Lorraine might prove a danger; in the East the Balkan problems were a constant potential source of war between Turkey and the Christian States of the Balkans, or between Russia and Austria. To avoid both dangers Bismarck wished to isolate France as far as possible, knowing that for a long time she would be unable, without powerful allies, to resume the struggle against Germany. In the East he wished, at least, to reconcile the interests of Russia and Austria, and thus to prevent war. When France began to entertain plans for colonial expansion in Africa and East Asia, Bismarck gave all possible encouragement to her endeavours, hoping that France, diverted from her single pursuit of the idea of revenge, would be compensated by the acquisition of a colonial empire for the loss of prestige which she had suffered in Europe.

In Eastern Europe Bismarck first sought to establish a close understanding between Germany, Russia and Austria, and thus to secure the possibility of intervention and mediation should disputes arise. For some time he seemed successful, but the Eastern crisis which broke out in consequence of the rising of Bosnia and the Herzegovina against Turkey in 1875 made the continuance of this policy impossible for the time. He refused an offer of alliance from Russia in 1876 in order not to desert Austria-Hungary and leave the Tsar the dominant figure in all South-Eastern Europe. Throughout the Russo-Turkish war of 1877-8 he continually exerted his offices to prevent the intervention of Austria or England in the conflict. At the Congress of Berlin, over which he presided, he pursued the same policy, and it was largely due to his endeavours that a compromise between the conflicting interests was found.

Russia was not satisfied with the result of these negotiations. She had been forced to renounce the establishment of a Great Bulgaria and leave Bosnia to Austria, and principally to the support which Bismarck had given to Austria she attributed her failure to harvest all the fruits of her victories. When Germany again supported Austria in the questions of frontier regulation, the Tsar Alexander II. assumed a directly threatening tone in a letter which he addressed to the emperor William. This led Bismarck to seek closer relations with Austria. He opened up conversations with Count Andrassy, the leading statesman of the Danube monarchy, and agreed with him on the draft of a defensive alliance against possible attack from Russia. The old emperor was very reluctant to give his consent to this draft, partly out of traditional respect for Russia, partly because he considered that such an alliance, which chiefly benefited Austria-Hungary, would be unacceptable to Germany unless it contained an assurance of help from Austria in case of an attack by France. Austria, however, refused to extend the treaty along these lines. Bismarck was so convinced of the necessity of this alliance that he threatened to resign unless the emperor approved it. Unable to face the loss of his great adviser, William I. ended by giving way, although unwillingly.

It was not, however, Bismarck's intention to commit himself wholly to Austria by this treaty, and to remain on permanently unfriendly terms with Russia. On the contrary, he desired to

re-establish good relations with St. Petersburg at the earliest possible opportunity, and in 1881 he succeeded in bringing about the Three Emperors' Alliance, which seemed to restore the old relations between the three Powers of Eastern Europe. It was renewed in 1884, at his instance, for a further three years. At the same time Bismarck yielded to Italy's wish to enter upon closer relations with Germany. He made the condition that Austria must be a party to this alliance. Italy consented, although unwillingly, the result being the conclusion of the Triple Alliance Treaty of 1882. By this move Bismarck not only prevented a possible alliance between France and Italy, but also ensured the possibility of mediating between Austria and Italy; and since Serbia and Rumania, by means of separate treaties, had also thrown in their lot with the Triple Alliance, the result was a great Central European defensive alliance against any attempt to alter the *status quo* in Europe. In the drafting of these treaties, Bismarck took care to limit their application solely to defence against attack by another power, and to make it quite impossible for any of the contracting parties to use them for aggressive purposes. He was also opposed to any further expansion of Austria in the Balkans, and for this reason, when the Triple Alliance was renewed in 1887, he advocated the insertion of a clause giving Italy a right to compensation if Austria came into permanent or temporary possession of further territory in the Balkan Peninsula. Bismarck's whole system of alliances, as expressed in these various treaties, aimed at preventing any of the participating States from taking individual action in regard to the extension of their existing territories, and at making it possible for Germany to intervene and mediate should disputes arise between them.

His policy aimed at the maintenance of peace; but it was put to a severe test when grave complications arose once more in the Balkans consequent on Russia's intervention in Bulgaria, the fall of Prince Alexander of Battenberg and the election of Ferdinand of Coburg to the Bulgarian throne. The tension between Austria and Russia again reached such a point that when the Three Emperors' Treaty expired in 1887, renewal of it was impossible. To preserve the basic principle of his policy, and to avoid breaking the thread with St. Petersburg, Bismarck now concluded the so-called "Reinsurance Treaty" with Russia, its purpose being the same as that of the earlier treaties, only its methods being different, and adapted to the new situation. Russia promised to remain neutral should France attack Germany, while Germany recognized Bulgaria as lying within the Russian sphere of influence, and even promised her diplomatic and moral support should Russia find herself compelled to undertake a temporary occupation of Constantinople. No permanent alteration of the territorial *status quo* in the Balkans might, however, be effected without previous arrangement with Germany. In concluding this treaty Bismarck did not in any way infringe the provisions of the German-Austrian treaty, which only guaranteed Austria's existing frontier, without allowing her any claim to extend her influence over Bulgaria. Bismarck had always taken the view that Russia and Austria should come to an understanding on the Balkan question, the former taking Bulgaria, the latter Serbia into her sphere of influence; and the Austrian statesmen had long been aware that this was his opinion. His purpose in concluding this treaty was not to encourage Russia to take military action, but to keep in close touch with the Russian court and thus to retain the possibility of affecting the Tsar's decisions in the direction of moderation. He was fully agreeable to Austria's concluding an agreement at the same time with England and Italy for the maintenance of the *status quo* in the Mediterranean and the Balkans, such a treaty being intended to safeguard the Danube monarchy against any Russian aggression. In these difficult circumstances, Bismarck thought that the only way to maintain peace was to keep in close touch with all the mutually mistrustful Powers, and, if possible, prevent collisions between them by Germany's conciliating influence. He did indeed succeed in preventing the outbreak of a European war in the critical years 1887 and 1888. Every detail of his policy was regulated by consideration for the general European situation. He knew that Germany's danger lay in the formation of an over-powerful hostile

coalition, and considered it the first object of German policy to prevent such an eventuality.

Bismarck's Colonial Policy.—His vision, however, was not confined to Europe. He saw that the development of world commerce and world communications, in which Germany's part grew more prominent from year to year, must also have political consequences. The partition of Africa among the great colonial Powers had begun soon after 1880, and it could only be a question of time before the same problem arose in Asia. In view of the importance of the overseas countries as markets for European commerce and sources of many raw materials indispensable for European industry, Germany could not stand aloof while other Powers partitioned up these countries. There had long been a demand for Germany to acquire colonies of her own. Bismarck had long been opposed to it. But when German commercial enterprises began to establish branches in parts of Africa which were not under the suzerainty of any European power, and to demand official protection for them, he felt that this ought not to be refused. Thus the acquisition of the first German colonies in 1884, although not due to his initiative, was to a great extent his work. But for his diplomatic intervention it would have been impossible to overcome the difficulties which arose from the opposition of the other colonial Powers, England in particular, to Germany's expansion. Bismarck never, indeed, proposed to found a German colonial empire, properly speaking; he only wished to ensure that, where the economic enterprise of German subjects had won a footing and created economic values on territory not claimed by other powers, such fruits of German labour should not be injured or destroyed. He considered that districts acquired in such fashion ought not to be considered as integral parts of the German empire, but as protectorates, to be administered by the firms which had founded them, and only protected by the empire against foreign aggression. Only later developments led to the abandonment of this point of view.

Bismarck remained true to the leading principles of his foreign policy to the end of his public career. He would have liked to extend the system of alliances which he had created to include England, and made repeated efforts to this end. His wishes, however, were received with marked reserve by English statesmen—first Lord Beaconsfield and later Lord Salisbury. They had scruples against promising their assistance in case of a French attack on Germany, while Bismarck considered this to be the essential point.

Bismarck's Domestic Policy: the "Kulturkampf."—Although Bismarck did not achieve all his ambitions in foreign policy, yet during the two decades in which he governed the new German empire, he was on the whole successful in this field, and at the end of his life was considered the leading statesman of Europe. His success in domestic policy during the same period was not so great. From the first the situation was difficult because the Government had not a safe majority. Apart from the opponents on principle of the new empire (the Poles, Danes and Guelfs), the Catholic party of the Centre, which disliked the rule of the Protestant dynasty of Hohenzollern, was hostile to the Government, as were the representatives of middle-class democracy, a comparatively weak group, most strongly represented in South Germany. Part, at least, of the Conservatives mistrusted Bismarck for the reasons discussed above. His chief supporters were the Liberal groups, the strongest of which was that of the National Liberals; but they never commanded a majority unsupported (in 1871 they had 125 deputies out of 382), and disagreed with Bismarck over many points of domestic policy. Bismarck desired to form a coalition (the so-called Cartel) between the National Liberals, after splitting off the left wing, which was too democratic for his views, and the Conservatives, and thus ensure himself a secure majority. But these parties themselves were not at present prepared for this step. For every separate legislative measure he was therefore obliged to conduct preliminary negotiations with the parties to secure a majority, which was never composed twice in the same way. Being unable in any case to do without the support of the National Liberals, he was forced to make extensive concessions to their wishes. At their desire, he extended the competence of the imperial legislature to the whole field of civil law, while the constitution had only proposed unification of the law of debentures and real

property. The laws on copyright, limited companies and the press were also liberal in conception; full liberty for trade and press was now introduced for the first time. In return the Liberals allowed the Chancellor to fix the period of service with the colours of the standing army at seven years (the so-called *Septennat*), despite their reluctance to consent to this limitation of the budgetary powers of parliament.

Bismarck was also in agreement with the Liberals when his great struggle against the claims of the Catholic Church, commonly known as the "Kulturkampf," began. It originated in action taken by the ecclesiastical authorities against those Catholics who refused to recognize the decisions of the Vatican Council of 1870, and their demand that the State should dismiss all such "Old Catholics" from teachers' posts in the State schools. Bismarck introduced a number of measures directed against interference by the ecclesiastical authorities in questions of state. The clergy were forbidden to discuss state questions in the pulpit. The regulation and supervision of education and of marriage were declared to be purely civil matters and withdrawn from the influence of the Church. The teaching of the monastic orders was placed under State supervision and the Jesuits expelled. In face of the opposition of the Catholic priests, the State not only instituted special tribunals, but also attempted to regulate the future preliminary training of priests on its own lines. When the pope forbade obedience to these laws, salaries were suspended and recalcitrant clergy dismissed. It is perhaps doubtful how far Bismarck was personally responsible for these measures. It is possible that he would not have done more on his own initiative than was necessary to prevent ecclesiastical interference in State affairs. In any case, however, he ended by approving the further measures, and supporting them in parliament, at first, indeed, with the intention of revoking part of them later when peace with the Church should prove possible. These measures excited very great bitterness throughout the Catholic population of Germany, and brought the Centre party many adherents.

Bismarck's Financial and Social Policy.—One of the great difficulties of the new empire was the construction of its financial system. Bismarck's plan was to take over all railways as an imperial concern and introduce a tobacco monopoly. Finding this impossible, he proposed increased tariffs, as demanded by the representatives of commerce and agriculture for economic reasons. This suggestion, however, encountered the violent opposition of the Liberal parties, the overwhelming majority of whom were free-traders. As Bismarck considered the increase of tariffs to be absolutely necessary, the attitude of the Liberals forced him to consider the possibility of getting together a majority in the Reichstag without them. This was only possible if the Conservatives and the Centre supported the Government motions. The support of the Centre could only be won if the State made peace with the Catholic Church. The death of Pope Pius IX and the election of the less uncompromising Leo XIII in 1878 seemed to offer an opportunity. Yet Bismarck still hesitated to take the decisive step, until a fresh conflict alienated him altogether from the Liberals.

The social question had long occupied his thoughts. The enormous increase of the class of factory workers attendant on the rapid development of Germany into an industrial state, and the growth of socialistic and radical doctrines among their ranks, filled him with concern. Fresh problems had been raised, and he saw that new measures would be necessary. These were to be twofold. On the one hand, he wished to offer the workmen permanent economic advantages through state-guaranteed insurance against sickness, accidents, old age and disability, and show them that they too might expect substantial advantages from the existing form of the State. At the same time he proposed to introduce stricter penal laws and subject to severe penalties any agitation against the existing form of State, property, marriage and the family. Here again he found the Liberals unsympathetic. They looked on compulsory insurance as an infringement of civic liberties, and emergency penal legislation as an offence against equality before the law. In the spring of 1878, shortly after two attempts, erroneously attributed to Social Democratic agitation, had been made

against the life of the aged emperor William, Bismarck, although aware of Liberal opinion, thought the time ripe to introduce emergency measures against Social Democracy. He dissolved the Reichstag after the second attempted assassination, by this stratagem securing a considerable increase in the strength of the Conservative party at the elections. The National Liberals, who had lost a large number of seats, now showed themselves ready to accept Bismarck's plan, to avoid losing all influence over the Government. The Socialist Act was passed in Oct. 1878 with the help of the National Liberals and the Conservatives. It declared illegal all associations, meetings and printed matter directed towards the overthrow of the existing form of society and State, and empowered the Government to place under supervision or to expel socialist agitators, and in extreme cases to proclaim a state of siege in whole districts. This law remained in force, with small modifications, till 1890.

Being unable to count on the help of the Liberals either for his tariff measures or for the workmen's insurance, Bismarck now determined at last to make his peace with the Centre party. His interview of March 31, 1879, with Windthorst, its most important leader, was a turning-point in his domestic policy. He secured the support of this party for the introduction of his tariff bill, which was effected on July 1879, agreeing in return to the revocation of the greater number of measures issued against the Catholic church in the preceding decade. The preliminary training of the clergy was again placed in the hands of the Church. The civil court of justice for ecclesiastical affairs was abolished; there remained only the obligation incumbent on the ecclesiastical authorities to furnish the State with personal details before filling an ecclesiastical post, in case the civil authorities desired to raise an objection. The revocation of the earlier laws was carried through gradually in the course of the next years, and it was only in 1887 that Leo XIII, in an address to the cardinals, was able to describe the conflict as closed.

Bismarck now returned to the idea of universal workmen's insurance, but was not able to carry it through to the full extent which he had wished. His plan embraced a great imperial insurance department, in which all factory workers and miners were to be insured, at first against accident. Although Bismarck induced the old emperor to send a special message to the Reichstag recommending the acceptance of this measure, he could not secure its passage in that form. He had to give up the imperial department; the contribution and administration of the funds was left to the employers and workers, who were organized for the purpose in trade associations. In this form the bill for insurance against injury became law in 1884; it was followed by similar acts for the institution of sick funds and insurance against old age and disability (1887), the arrangements regarding contribution and administration being somewhat altered.

All this legislation is certainly only patch-work compared to Bismarck's original conception. Instead of a great imperial department there were a number of mutually independent funds, the respective competencies of which were ill-defined. In these circumstances the workmen could not become imbued with the feeling that they were receiving the advantages of the new legislation direct from the empire. Their sentiments towards the existing State remained as negative as ever. But the State had abandoned its purely passive attitude towards social problems and had become conscious of its duties and rights in view of the increasing frequency of social conflicts. Bismarck can claim the personal credit of having established the view, in the face of public opinion and the dominant theories in Germany, that one of the most important positive tasks of the state is the establishment and maintenance of social peace, and that the state shatters the foundations of its power if it neglects this duty. Whether the means which he tried to employ to reach this end were always the right ones is, of course, another question; in any case the application of emergency measures and force against those currents which he thought too extreme had not the success which he anticipated.

A general survey of Bismarck's domestic policy after the foundation of the empire reveals, as its chief defect, his failure to indicate the direction in which national institutions should develop in

order to keep pace with the radically altered economic and social conditions in his country. His own views and feelings were too deeply rooted in the old predominantly agricultural era and the feudal class which had been supreme in that era. His intellect and keen political eye showed him the importance of the new problems which arose with the transition to an industrial state, and in certain respects he met them. In his heart of hearts, however, he could never sympathize with the institutions of the modern political life of which he was himself the author. He looked on domestic politics as a tactical struggle in which the business of the Government was to get its way in the face of the parties by cleverly exploiting their disunion. The people was and remained in his eyes purely a thing to be governed, unfit, in his opinion, to influence the conduct of its own affairs in any large degree.

Accession of William II.: Bismarck's Fall.—In these circumstances his whole position depended on his close agreement with the sovereign, to whom he owed his appointment and his authority, and whose confidence had kept him at his post so long despite all changes of political majorities and vagaries of public opinion. So long as Emperor William I lived he could be certain that this foundation of his position would never be shaken. The old emperor had, indeed, often opposed his advice vehemently, but had always given way in the end when he saw that Bismarck's decision was unalterable, being unable to bear the idea of parting from the man who had stood by his side through his whole reign and whom he had to thank for his great successes. When William I. died on March 9, 1888, at the age of 91, the situation changed entirely for Bismarck. The new emperor, Frederick, who had always inclined, at heart, to Liberal views, might have left him in office; but he was a dying man, and destined only for a short span of life. The young emperor William II., who succeeded his father on June 14, 1888, had always shown the greatest admiration for Bismarck; but he was a man of strong self-will and uncontrolled temperament, and it could not be expected that he would in all circumstances bow before the authority of a minister who belonged to a quite other generation and, as was soon to appear, differed wholly from him in his entire way of political thought and action.

The conflict between the two men that led to Bismarck's dismissal began soon after William II.'s accession and became so acute in the spring of 1890 that reconciliation no longer seemed possible. The actual points at issue—the prolongation of the anti-Socialist law and the emperor's desire to introduce far-reaching labour legislation—were not of decisive importance. The real point was that the emperor saw in Bismarck's opposition to his plans in both cases an attempt to prevent him from carrying out his own ideas in the conduct of imperial policy. If gossips, who are never lacking at such moments of crisis, told the emperor that Bismarck was attempting to get for himself and his family the position of a mayor of the palace, like that of the Carolingians in old France before the dethronement of the Merovingians, they had touched here on the emperor's feelings and fears. He felt himself most painfully oppressed and cramped by the aged and experienced statesman's overwhelming authority, not always expressed in the most tactful way, while he yet felt it to be his good right as monarch to have the last decision himself in all questions.

It is indubitable that during the weeks through which this struggle lasted, Bismarck endeavoured by all means in his power to retain his office even against the will of the emperor. This was not only from personal ambition, although it was certainly hard for him to renounce the power he had so long wielded, but also from a conviction that a personal régime of William II. would have fatal consequences for Germany. He attempted to persuade the other ministers to say that they would stand or fall with him; but he had himself always supported the view that a minister must be in the first instance a servant of his sovereign, and this conviction also animated his colleagues. Faced with the choice between obedience to their monarch or to their minister-president, they chose the former. When Bismarck revived an old cabinet order forbidding individual ministers to render account to the sovereign except in the presence of the minister-president, the emperor demanded the revocation of that order. On Bismarck's refusing to obey this command, the emperor let him know that he expected him to re-

sign. Neither could Bismarck expect public opinion to afford him any strong support. His great services lay in the past, and were already half forgotten by the mass of the people. He had already embittered the Catholics by his ecclesiastical legislation, he had alienated himself from the Liberals, the workmen saw in him only a representative of the class State and class domination; thus he could not expect that the great mass of the people would unite to support him in this conflict. He was obliged to give way to the emperor's demand, and on March 18, 1890, he offered his resignation, which was immediately accepted. The honours which the emperor conferred on him at the same time, particularly his promotion to be duke of Lauenburg, could not conceal the fact that emperor and chancellor had parted as personal enemies.

The great tragedy in Bismarck's life is that he fell by the application of that very principle the maintenance of which he had urged with all his powers; that the sovereign in the last resort must be the decisive power in the State, the ministers representing only the executive organs of his will.

Bismarck's Last Years and Death.—After his dismissal Bismarck retired to Friedrichsruh, near Hamburg. Here he passed the last eight years of his life in sullen retirement in the old manor-house in the Sachsenwald. He often criticized the policy of the emperor and his new advisers sharply, both in conversations with his frequent visitors and in the articles which he published in the *Hamburger Nachrichten*. This was very disagreeable to the new men, and they let him feel their anger at every opportunity. The most undignified manifestation of this hatred took place on a journey which Bismarck made to Vienna in June, 1892, to attend his son's wedding. The German ambassador in Vienna was ordered to see that the aged statesman was completely ignored in official circles. Only when Bismarck fell gravely ill in 1893 was he reconciled with the emperor William II. This, however, made no change in his attitude towards the "new course."

Having now no field for action, Bismarck attempted to lay all his experiences and ambitions before his contemporaries and posterity in a great literary monument. His *Gedanken und Erinnerungen*—the two first volumes of which were issued immediately after his death, while the third volume, dealing with the period of his dismissal, only appeared after the fall of William II.—are his political testament. The historical portions are not invariably accurate in detail and show the shortcomings of all recollections written from memory after the event. As a whole, however, the work gives us the noblest and most truthful picture of Bismarck as a statesman; one-sided and ruthless, as he always was in action, so he is as writer and critic of his contemporaries; from both his actions and the pages of this book emanates the breath of mighty political passions, softened by supreme practical intelligence. The work forms the great statesman's last legacy to his nation and to the world. He died in Friedrichsruh on July 28, 1898, at the age of 83, three years after the death of his wife. In his last words he expressed his devotion to his old emperor and his dislike of his new master by choosing the following inscription for his tomb:

"A true German servant of the Emperor William I."

BISMARCK, the capital of North Dakota, U S A, and the county seat of Burleigh county, on the east bank of the Missouri river, in the south-central part of the State. It is on Federal

Highway 10 and the main line of the Northern Pacific railway, and is served also by the Soo line. A tract of land has been set aside for an airport, and a revolving beacon has been installed on the roof of one of the hotels. The population was 7,122 in 1920, (15% foreign-born white); 9,150 in 1925 (State census).

The city is 1,692 ft. above sea-level. The annual precipitation is 18 or 19 in. and the extremes of temperature range from -40° to over 100° . It lies in the heart of the spring wheat region, where diversified farming, dairying, fruit and truck-raising are growing industries, and is the supply centre for a wide agricultural territory. The lignite mines of the county employ several hundred men. There are several Federal offices in Bismarck, as well as the State departments and the State penitentiary. On the capitol grounds is the log-house from Roosevelt's Dakota ranch; and across the river, in a State park, is Ft. Abraham Lincoln, from which Custer started on his last expedition. The city has a commission form of government.

The first white man whose visit to this region is recorded was Verendrye (1738-42). Lewis and Clark wintered 50 m. north of Bismarck in 1804-05. The city was founded in 1873 and incorporated in 1876. It was the western terminus of the Northern Pacific from 1873, when construction was suspended, on account of the financial panic, until 1878. From 1883 to 1889 it was the capital of Dakota Territory, and when the territory was divided it became the capital of the northern State.

BISMARCK ARCHIPELAGO, the collective name of a large number of islands lying north and north-east of New Guinea, between 1° and 7° S, and 146° and 153° E., which were a German protectorate from 1885, but under the Treaty of Versailles (1919) were made part of the mandated territory of New Guinea and mandated to Australia. The largest island is New Britain (formerly New Pomerania), and the archipelago also includes New Ireland (formerly New Mecklenburg), Lavongai (formerly New Hanover), with small attendant islands, the Admiralty islands and a chain of islands off the coast of New Guinea, the whole system lying in the form of a great amphitheatre of oval shape (See ADMIRALTY ISLANDS; NEW IRELAND; NEW BRITAIN; NEW GUINEA.)

BISMARCK-SCHÖNHAUSEN, HERBERT PRINCE VON (1849-1904). German diplomat, the eldest son of the great Chancellor, was born on December 28, 1849, and was early destined for a diplomatic career. After leaving the University of Bonn, Count Herbert Bismarck took part in the Franco-Prussian War, and was severely wounded in the famous charge of the 1st Guards Dragoons at Mars-la-Tour. Entering the diplomatic service he became councillor at the German embassy in London in 1882. In London he won for himself many friends and, with the possible exception of Prince Münster and Count Hatzfeldt, Herbert Bismarck understood England and English habits of thought better than any of his contemporaries. In 1885 his father made him Under-Secretary for Foreign Affairs, and in the following year obtained for him the secretaryship. Between 1886 and 1890 he was his father's right-hand man in the Wilhelmstrasse. He was mainly responsible for the Samoan Agreement between Germany, England and America, signed in 1889, and he has been held to be the author of the *condominium* set up by that Agreement in Samoa. Another achievement, and one for which he was severely censured in Germany, was the conclusion of the East African Convention of 1890 by which Germany obtained Heligoland in exchange for her rights, real or alleged, over Zanzibar and her possession of Wituland. When, in 1890, the great Chancellor fell from power, Herbert Bismarck ranged himself on his father's side. Despite a personal appeal from the Kaiser to remain in office, he resigned and for some years completely retired from public life. During these years, and until his father's death in 1898, Herbert Bismarck stayed by the aged Chancellor, aiding him in his campaign against the "New Course" on which the Kaiser was steering Germany. At the same time he is believed to have disapproved of many of his father's more violent outbursts in the Press. In 1892 he married the Countess Margaret Hoyos—the wedding in Vienna being taken advantage of by the Kaiser to give a public snub to Prince Bismarck. A year later he entered the *reichstag* as an

WEATHER GRAPH OF BISMARCK, NORTH DAKOTA. THE THERMOMETER INDICATES MEAN ANNUAL TEMPERATURE. THE MIDDLE CURVE SHOWS MONTHLY MEAN TEMPERATURE. THE CURVES ABOVE AND BELOW, THE HIGHEST AND LOWEST TEMPERATURE EVER RECORDED IN EACH MONTH. THE COLUMNS INDICATE MONTHLY PRECIPITATION: THE SOLID COLUMN, TOTAL PRECIPITATION (INCLUDING MELTED SNOW); THE WHITE COLUMN, SNOWFALL.

"Independent," but he invariably voted with the Free Conservatives and revealed himself an extremist in agrarian policy. Although he had very largely been the Kaiser's mentor in foreign affairs, their former cordial relations were never resumed after the Chancellor's dismissal; but with Hohenlohe and Bülow his relations were at any rate outwardly friendly. In the few years of life that remained to him after his father's death Herbert Bismarck showed himself an opponent of *Weltpolitik* and of a policy of colonial expansion.

He succeeded to his father's title on July 30, 1898, and died at Friedrichsruh on Sept. 18, 1904, being succeeded in his title and estates by his eldest son, Prince Otto von Bismarck-Schönhausen.

BIBLIOGRAPHY.—The best sketch of Herbert Bismarck's character is to be found in the writings of his intimate friend Prince Philipp zu Eulenburg-Hertefeld—*Aus 50 Jahren* (1923). A selection from his public speeches was published in 1905 under the title *Fürst Herbert von Bismarck's politische Reden*. (I. F. D. M.)

BISMILLAH, an Arabic exclamation, meaning "in the name of God."

BISMUTH, a metallic element; it was probably unknown to the Greeks and Romans, but in the middle ages it became familiar, notwithstanding its frequent confusion with other metals. In 1450 Basil Valentine referred to it by the name "wismut"; some years later Paracelsus termed it "wissmat," and, in allusion to its brittle nature, affirmed it to be a "bastard" or "half-metal"; Georgius Agricola used the form "wissmuth," latinized to "bise-mutum," and also the term "plumbum cinereum." Its elementary nature was imperfectly understood; and the impure specimens obtained by the early chemists explain, in some measure, its confusion with tin, lead, antimony, zinc and other metals; in 1595 Andreas Libavius confused it with antimony, and in 1675 Nicolas Lemery with zinc. These obscurities began to be elucidated by the researches of Johann Heinrich Pott (1692–1777), a pupil of Stahl, published in his *Exercitationes chemicae de Wismutho* (1769), and of N. Geoffroy, whose contribution to our knowledge of this metal appeared in the *Mémoires de l'Académie française* for 1753. Torbern Olof Bergman reinvestigated its properties and determined its reactions; his account, published in his *Opuscula*, contains the first fairly accurate description of the metal. Its symbol is Bi, its atomic number 83, and its atomic weight 209.

Ores and Minerals.—The native metal is usually found either in reticulated and arborescent shapes or as foliated and granular masses with a crystalline fracture. Although bismuth is readily obtained in fine crystals by artificial means, yet natural crystals are rare and usually indistinct. Bismuth crystals, like those of arsenic and antimony, belong to the rhombohedral system, the three elements forming an isomorphous series. When not tarnished, the mineral has a silver-white colour with a tinge of red, and the lustre is metallic. Hardness 2–2½; specific gravity 9.70–9.83. The slight variations in specific gravity are due to the presence of small amounts of arsenic, sulphur or tellurium, or to enclosed impurities.

Bismuth occurs in metalliferous veins traversing gneiss or clay-slate, and is usually associated with ores of silver and cobalt. Well-known localities are Schneeberg in Saxony and Joachimsthal in Bohemia; at the former it has been found as arborescent groups penetrating brown jasper, which material has occasionally been cut and polished for small ornaments. Considerable deposits of bismuth occur in South Australia, California, Ontario, Spain, southern China, Rhodesia and India. The mineral has been found in some Cornish mines and is fairly abundant in Bolivia; the latter country is the chief commercial source of bismuth and the principal ore is a hydrated bismuth oxide.

The oxide, bismuth ochre, Bi₂O₃, and the sulphide, bismuth glance or bismuthinite, are also of commercial importance. The former is found, generally mixed with iron, copper and arsenic oxides, in Bohemia, Siberia, Cornwall, France (Meymac) and other localities; it also occurs admixed with bismuth carbonate and hydrate.

Metallurgy.—The dry process of extraction is most frequently practised, for the easy reducibility of the oxide and sulphide, together with the low melting-point of the metal, renders it possible to effect a ready separation of the metal from the gangue and im-

purities. The extraction from ores in which the bismuth is present in the metallic condition may be accomplished by a simple liquation, or melting, in which the temperature is just sufficient to melt the bismuth, or by a complete fusion of the ore. The first process never extracts all the bismuth, as much as one-third being retained in the matte or speiss; the second is more satisfactory, since the extraction is more complete, and also allows the addition of reducing agents to decompose any admixed bismuth oxide or sulphide. In the liquation process the ore is heated in inclined cylindrical retorts, and the molten metal is tapped at the lower end, the residues being removed from the upper end. The fusion process is preferably carried out in crucible furnaces.

Sulphide ores are smelted, either with or without a preliminary calcination, with metallic iron; calcined ores may be smelted with carbon (coal). The reactions are strictly analogous to those which occur in the smelting of galena (*see* LEAD), the carbon reducing any oxide, either present originally in the ore or produced in the calcination, and the iron combining with the sulphur of the bismuthinite. A certain amount of bismuth sulphate is always formed during the calcination; this is subsequently reduced to the sulphide and ultimately to the metal in the fusion. Calcination in reverberatory furnaces and a subsequent smelting in the same type of furnace with the addition of about 3% of coal, lime, soda and fluorspar, has been adopted for treating the Bolivian ores, containing the sulphides of bismuth, copper, iron, antimony, lead and a little silver. The lowest layer of the molten mass is principally metallic bismuth, the succeeding layers are a bismuth copper matte, which is subsequently worked up, and a slag. Ores containing the oxide and carbonate are treated either by smelting with carbon or by a wet process.

In the wet process the ores, in which the bismuth is present as oxide or carbonate, are dissolved out with hydrochloric acid, or, if the bismuth is to be extracted from a matte or alloy, the solvent employed is *aqua regia* or sulphuric acid. The solution of metallic chlorides or sulphates so obtained is precipitated by iron, the metallic bismuth filtered, washed with water, pressed in canvas bags, and finally fused in graphite crucibles, the surface being protected by a layer of charcoal. Another process consists in adding water to the solution and so precipitating the bismuth as oxychloride, which is then converted into the metal by heating with charcoal and sodium carbonate.

The crude metal obtained by the preceding processes is generally contaminated by arsenic, sulphur, iron, nickel, cobalt and antimony, and sometimes with silver or gold. A dry method of purification consists in a liquation on a hearth of peculiar construction, which occasions the separation of the unreduced bismuth sulphide and the bulk of the other impurities. The wet refining process is tedious and expensive, and is only exceptionally employed, as in the case of preparing the pure metal or its salts for pharmaceutical or chemical purposes. The basic nitrate is the salt generally prepared, and in general outline the process consists in dissolving the metal in nitric acid, adding water to the solution, boiling the precipitated basic nitrate with an alkali to remove the arsenic and lead, dissolving the residue in nitric acid, and reprecipitating as basic nitrate with water. Chemically pure bismuth is obtained by fusing the metal with sodium carbonate and sulphur, dissolving the bismuth sulphide so formed in nitric acid, precipitating the bismuth as the basic nitrate, redissolving this salt in nitric acid, and then precipitating with ammonia. The bismuth hydroxide so obtained is finally reduced by hydrogen.

A considerable proportion of the bismuth manufactured in the U.S.A. is derived from anode slimes obtained in the Betts process for desilverizing lead. These slimes are fused with sodium hydroxide and carbonate to remove lead and arsenic and with sodium sulphide to extract copper. The residue, containing 94% bismuth with silver and gold, is cast into slabs and made the anode of a second electrolytic process with bismuth chloride electrolyte; pure bismuth is deposited at the cathode, gold and silver being precipitated at the anode.

Properties.—Bismuth is a very brittle metal with a white crystalline fracture and a characteristic reddish-white colour. The specific gravity of solid bismuth is 9.82, and of molten bismuth

is 10.055. The metal therefore expands on solidification; and as it retains this property in a number of alloys, the metal receives extensive application in forming type-metals. Bismuth melts at 271°C , is appreciably volatile at red heat and boils at about $1,500^{\circ}\text{C}$. At $1,700^{\circ}\text{C}$ its vapour contains a mixture of monatomic and diatomic molecules. Its thermal conductivity is the lowest of all metals, being 18 as compared with silver as 1,000; its coefficient of expansion between 0° and 100° is 0.001341. Its electrical conductivity is approximately 1.2, silver at 0° being taken as 100; it is the most diamagnetic substance known, and its thermoelectric properties render it especially valuable for the construction of thermopiles.

The metal tarnishes very slowly in dry air at ordinary temperatures, but somewhat more rapidly in moist air or when heated. At a bright red heat it burns with a bluish flame to the trioxide. Bismuth combines directly with the halogens, and with the elements of the sulphur group. It readily dissolves in nitric acid, *aqua regia*, and hot sulphuric acid, but tardily in hot hydrochloric acid. It is precipitated as the metal from solutions of its salts by the metals of the alkalis and alkaline earths, zinc, iron, copper, etc. In its chemical affinities it resembles arsenic and antimony; but its hydride (BiH_3 ?) is only obtained in minute traces by the action of nascent hydrogen on bismuth salts.

Alloys.—When present in other metals, even in very small quantity, bismuth renders them brittle and impairs their electrical conductivity. Bismuth is a component of many alloys characterized by their low fusibility and expansion in solidification. Its eutectics with lead and with tin melt at 127°C and 133°C respectively. Ternary and quaternary alloys have even lower melting points (see FUSIBLE METAL).

Compounds.—Bismuth trioxide, Bi_2O_3 , occurs in nature as bismuth ochre, and may be prepared artificially by oxidizing the metal at a red heat, or by heating the carbonate, nitrate or hydrate. Thus obtained it is a yellow powder, soluble in the mineral acids to form soluble salts, which are readily precipitated as basic salts when the solution is diluted. It melts to a reddish-brown liquid, which solidifies to a yellow crystalline mass. The hydrate, $\text{Bi}(\text{OH})_3$, is obtained as a white powder by adding potash to a solution of a bismuth salt. When chlorine oxidizes bismuth trioxide suspended in caustic potash, potassium bismuthate KBiO_4 is obtained. The alkali bismuthates are employed as oxidizing agents in analysis. The corresponding hydrate HBiO_4 has been isolated. Bismuth pentoxide, Bi_2O_5 , is obtained by heating bismuthic acid, HBiO_3 , to 130°C .

Bismuth trichloride, BiCl_3 , obtained by Robert Boyle by heating the metal with corrosive sublimate, is the final product of burning bismuth in an excess of chlorine. It is a white substance, melting at $225^{\circ}\text{--}230^{\circ}\text{C}$ and boiling at $435^{\circ}\text{--}441^{\circ}$. With excess of water, it gives a white precipitate of the oxychloride, BiOCl . Bismuth trichloride forms double compounds with hydrochloric acid, the chlorides of the alkaline metals, ammonia, nitric oxide and nitrosyl chloride. The other bismuth halides closely resemble the trichloride in their methods of preparation and their properties, forming oxyhalides, BiOX , with water, and double compounds with ammonia, etc.

Carbonates.—The basic carbonate, $2(\text{BiO})_2\text{CO}_3 \cdot \text{H}_2\text{O}$, obtained as a white precipitate when an alkaline carbonate is added to a solution of bismuth nitrate, is employed in medicine. Another basic carbonate, $3(\text{BiO})_2\text{CO}_3 \cdot 2\text{Bi}(\text{OH})_3 \cdot 3\text{H}_2\text{O}$, constitutes the mineral bismutite.

Nitrates.—The normal nitrate, $\text{Bi}(\text{NO}_3)_3 \cdot 5\text{H}_2\text{O}$, is obtained in large transparent asymmetric prisms by evaporating a solution of the metal in nitric acid. The action of water on this solution produces a crystalline precipitate of basic nitrate, probably $\text{Bi}(\text{OH})_2\text{NO}_3$, though it varies with the amount of water employed. This precipitate constitutes the "magistery of bismuth" or "subnitrate of bismuth" of pharmacy, and under the name of pearl white, *blanc d'Espagne* or *blanc de fard* has long been used as a cosmetic.

Sulphides.—Bismuth combines directly with sulphur to form a disulphide, Bi_2S_3 , and a trisulphide, Bi_2S_5 , the latter compound being formed when the sulphur is in excess. Bismuth trisulphide,

Bi_2S_5 , constitutes the mineral bismuthinite, and may be prepared by direct union of its constituents, or as a brown precipitate by passing sulphuretted hydrogen into a solution of a bismuth salt. It is easily soluble in nitric acid. When heated to 200°C it assumes the crystalline form of the mineral. Bismuth forms compounds similar to the trisulphide with selenium and tellurium. The tritelluride constitutes the mineral tetradymite, Bi_2Te_3 .

Bismuth sulphate, $\text{Bi}_2(\text{SO}_4)_3$, is obtained as a white powder by dissolving the metal or sulphide in concentrated sulphuric acid. Water decomposes it, giving a basic salt, $\text{Bi}_2(\text{SO}_4)(\text{OH})_2$, which on heating gives $(\text{BiO})_2\text{SO}_4$.

Analysis.—Traces of bismuth may be detected by treating the solution with excess of tartaric acid, potash and stannous chloride, a precipitate or dark coloration of bismuth oxide being formed even when only one part of bismuth is present in 20,000 of water. If bismuth is present heating on charcoal with potassium iodide and sulphur gives a brilliant scarlet incrustation. The blackish brown sulphide precipitated from bismuth salts by sulphuretted hydrogen is insoluble in ammonium sulphide, but is readily dissolved by nitric acid.

Pharmacology and Therapeutics.—In the older therapeutic applications of bismuth compounds the following salts have been employed, the benzoate, carbolate, carbonate, citrate (including the double ammonio citrate contained in *liquor bismuthi et ammonii citratis B.P.*), oxide, salicylate, sulphocarbonate, subnitrate (basic nitrate), subgallate and tannate. These substances have an extended vogue in various disorders of the digestive tract on account of their ability to form a coating—probably bismuth oxychloride—which protects the lining membranes from irritation. Such bismuth salts have also sedative, astringent and antiseptic properties; they are safe drugs owing to the absence of remote actions. The faeces are coloured black owing to the formation of bismuth sulphide.

Bismuth carbonate, oxychloride and subnitrates are employed for diagnostic purposes in X-ray examinations, when these compounds serve to determine the outline of the oesophagus, stomach and other sinuses in different parts of the body.

A compound known as "B.I.P.P." extensively used as a dressing for wounds during the World War, is composed of iodoform and the subnitrate made into a cream with liquid paraffin.

A more recent employment of bismuth compounds is in replacing mercurials in the treatment of syphilis. Neutral sodium bismuthyl tartrate and sodium potassium bismuthyl tartrate in solution, or more generally in suspension, have been injected intramuscularly. But as these applications are attended by local pain and by secondary effects on skin and mucous membranes, digestive tract and kidneys, a fine suspension of metallic bismuth has been recommended also for intramuscular injection. Considerable doses are given as the metal is slower than arsenic in the form of arsenobenzene in healing active signs of disease.

Bismuth hydroxide and salicylate have been similarly employed and the French Codex, Nouveau Supplement, 1926, indicates quinine iodo-bismuthate with directions for preparing a suspension for injection.

See W. H. Martindale and W. W. Westcott, *Extra Pharmacopoeia* (1926); new ed., Vol. 1, 1928. (G. T. M.)

BISMUTHINITE, a somewhat rare mineral, consisting of bismuth trisulphide (Bi_2S_5). It crystallizes in the orthorhombic system and is isomorphous with stibnite (Sb_2S_3), which it closely resembles in appearance. It forms loose interlacing aggregates of acicular crystals, or as masses with a foliated or fibrous structure. An important character is the perfect cleavage in one direction parallel to the length of the needles. The colour is lead-grey. The hardness is 2; specific gravity 6.4–6.5.

BISON, the name applied in Europe to *Bison europaeus* and to *B. americanus* of N. America, in which country the latter is called "buffalo." These animals are distinguished from the typical oxen of the genus *Bos* by their great breadth, the convexity of their foreheads, their longer limbs, the hump on the shoulders, and by having 14 instead of 13 ribs. The forehead, neck and shoulders (the shoulders only in winter in *B. europaeus*) are covered with long, shaggy, dark-brown hair.

Formerly inhabiting the whole of Europe, the European species is now restricted to the forests of the Caucasus and a few parks in Russia and Lithuania. The American bison, once roaming the prairies in countless millions, nearly became extinct at the end of the last century, but is now protected and is increasing in the national parks of the United States and Canada.

The beef of the bison is nearly equal to that of domestic cattle.

There are two races of the American animal, the prairie form and a smaller woodland variety. The bison feeds on grass and the leaves, twigs, shoots and bark of trees

BISQUE (a French word of unknown origin, formerly spelt in English "bisk"), a term for odds given in the games of tennis, lawn tennis, croquet, and golf; in the two former a bisque is one point to be taken at any time during a "set" at the choice of the receiver of the odds, while in croquet and golf it is one extra stroke or turn to be taken similarly. The name is given, in cookery, to a thick soup, made particularly of crayfish or lobsters.

BISSELL, GEORGE EDWIN (1839-1920), American sculptor, was born at New Preston (Conn.), on Feb. 16, 1839. During the Civil War he served as a private in the 23rd Connecticut volunteers in the department of the gulf (1862-63), and on being mustered out became acting assistant paymaster in the South Atlantic squadron. He studied the art of sculpture abroad in 1875-76, and lived much in Paris during the years 1883-96, with occasional visits to America. Among his more important works are the soldiers' and sailors' monument, and a statue of Col. Chatfield, at Waterbury (Conn.); of Gen. Gates at Saratoga (N.Y.); of Chancellor John Watts in Trinity churchyard, New York city; of Col. Abraham de Peyster in Bowling Green, New York city; of Abraham Lincoln at Edinburgh; of Burns and "Highland Mary," in Ayr, Scotland; of Chancellor James Kent, in the congressional library, Washington; and of President Arthur in Madison square, New York city. He died on Aug. 30, 1920, at Mt. Vernon, New York.

BISSEXT or **BISSEXTUS**, the day intercalated by the Julian calendar in the February of every fourth year to make up the six hours by which the solar year was computed to exceed the year of 365 days. The day was inserted after Feb. 24, i.e., the sixth day before the calends (1st) of March; there was consequently, besides the *sextus*, or sixth before the calends, the *bissextus* or "second sixth," our Feb. 25. Hence the name "bissextile" for leap year.

BISSOLATI-BERGAMASCHI, LEONIDA (1857-1920), Italian politician, was born at Cremona, Feb. 20 1857. The son of Demetrio Bergamaschi, he was adopted by and took the name of his stepfather, Prof. Bissolati, the philosopher. He was an active member of the Italian Socialist party from its foundation in 1892, and he exercised considerable influence as a journalist, editing the official organ of the party, *L'Avanti*. In 1897 he entered parliament as member for Pescarolo and was afterwards elected for the second division of Rome (1908), which he represented until his death. Although a confirmed Socialist, Bissolati became dissatisfied with certain aspects of the policy of the party, notably with its anti-patriotic attitude at the time of the Libyan War. In 1912 he seceded from the party and founded the Reformist Socialist group. At the outbreak of the World War Bissolati declared himself an interventionist, whereas the "official" Socialist party was frankly neutral. In June 1916 he was minister without portfolio in the Boselli National cabinet. He resigned in Dec. 1918 owing to disagreements with Signor Orlando's Government over the Treaty of London. He opposed the annexation of the Alto Adige because of its German population and of north Dalmatia with its Slav majority; but he advocated the annexation of Fiume as a purely Italian town. His attitude on the Alto Adige and Dalmatian questions lost him much

BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE BISON, NOW ALMOST EXTINCT ON THE PLAINS OF NORTH AMERICA WHERE IT ROAMED IN COUNTLESS NUMBERS A HUNDRED YEARS AGO

of his former popularity, but his undoubted honesty and patriotism caused wide regret for his death, which occurred at Rome on May 6 1920.

BISTRE, the French name of a brown paint made from the soot of wood; now largely superseded by Indian ink.

BISTRITA, a town of Transylvania, Rumania, capital of the department of Nasaüd, situated on the river Sieul, on the edge of the Carpathian mountains. Pop. (1925), 13,000, including 5,000 Germans, 4,000 Rumanians. A railway runs west to the main system, via Dej; 18m. east of Bistrița (at Borgo Bistrița) the line ends, but a motor train runs through the mountains to the watering-place of Dornavatra and the Bukovina. Bistrița is a Saxon settlement, centre of the old "Nösnerland." There is an interesting Gothic church with Oriental carpets (*cf.* Braşov) and arcaded market-place.

BIT, a piece of anything. The word is used in various special senses, all derivable from its origin ("to bite"), either literally or metaphorically. The most common of these are (1) its use as the name of various tools; *e.g.*, centre-bit; (2) a horse's "bit," or the metal mouthpiece of the bridle; (3) a small sum of money of varying value; *e.g.*, threepenny bit. In the United States, especially the western part, the term "two bits" is commonly used for twenty-five cents.

BITCHE (Ger. *Bitsch*), town, France, department of Moselle, on the Horn, at the north foot of the Vosges between Hagenau and Sarreguemines. Pop. (1926) 2,327. The town, formed of the villages of Rohr and Kaltenhausen in the 17th century derives its name from the stronghold (mentioned in 1172 as Bytis Castrium) on a rock some 250ft. above it. This had given its name to the countship of Bitsch, once belonging to the dukes of Lorraine. In 1297 it passed by marriage to Eberhard I of Zweibrücken, whose line became extinct in 1569, when the countship reverted to Lorraine. It passed with that duchy to France in 1766. The citadel on the site of the old castle was restored and strengthened in 1740. It was defended in 1793, 1815 and 1870. It was restored with the neighbouring regions to France in 1919. Industries include shoe-making and watch-making, and trade in grain and timber.

BITHUR, a town in the Cawnpore district of the United Provinces of India, 12 m. N.W. of Cawnpore city. Pop. (1921) 2,305. The last of the peshwas, Baji Rao, was banished to Bithur, and it was his adopted son, the Nana Sahib, who became the villain of the Cawnpore tragedy in 1857. The town was captured by Havelock on July 19, 1857, when the Nana's palaces were destroyed.

BITHYNIA, a district in the north-west of Asia Minor (Gr *Βιθυνία*), adjoining the Propontis, the Thracian Bosphorus and the Euxine (*q.v.*). On the east it adjoined Paphlagonia, on the west and south-west Mysia, and on the south Phrygia and Galatia. It is in great part occupied by mountains and forests, but has valleys and districts of great fertility near the sea-coast. The most important mountain range is the "Mysian" Olympus (7,600ft.), whose summits are covered with snow for a great part of the year. The country between the mountains and the coast, covered with forests and traversed by few lines of route, is imperfectly known. The west coast is indented by two deep inlets, the Gulf of Ismid (anc. Gulf of Astacus), and the Gulf of Mudania or Gemlik (Gulf of Cius).

The principal rivers are the Sangarius (mod. Sakaria), which traverses the province from south to north, and the Billaeus (Filiyas), which rises in the Ala-Dagh, about 50m. from the sea, and after flowing by Boli (anc. Claudiopolis) falls into the Euxine, about 40m. N.E. of Heraclea, having a course of more than 100m.

The natural resources of Bithynia are imperfectly developed. Its forests would furnish vast supplies of timber if rendered accessible. Coal is known to exist near Eregli (Heraclea). The valleys towards the Black Sea abound in fruit trees of all kinds, while the valley of the Sangarius and the plains near Brusa and Isnik (Nicaea) are fertile and well cultivated. Extensive plantations of mulberry trees supply the silk for which Brusa has long been celebrated.

The ancient Bithynians were an immigrant Thracian tribe.

Herodotus (i. 28) mentions the Thyni and Bithyni as existing side by side; but ultimately the latter became the more important, and gave their name to the country. They were incorporated by Croesus (q.v.) with the Lydian monarchy, with which they fell under the dominion of Persia (546 B.C.). Before the conquest by Alexander the Bithynians asserted their independence, under Bas and Zipoetes, the last of whom transmitted his power to his son Nicomedes I., the first to assume the title of king. This monarch founded Nicomedia, which soon rose to great prosperity, and during his long reign (278-250 B.C.), as well as those of his successors, Prusias I., Prusias II., and Nicomedes II. (149-91 B.C.), the kingdom of Bithynia held a considerable place among the minor monarchies of Asia. The last king, Nicomedes III., was unable to maintain himself against Mithridates of Pontus, and, after being restored to his throne by the Roman senate, he bequeathed his kingdom by will to the Romans (74 B.C.). Bithynia now became a Roman province. Its limits were frequently varied, and it was often united for administrative purposes with the province of Pontus. This was the state of things in the time of Trajan, when the younger Pliny was appointed governor of the combined provinces, (A.D. 103-105). Under the Byzantine empire Bithynia was again divided into two provinces, separated by the Sangarius, to the west of which the name of Bithynia was restricted.

The most important cities were Nicomedia and Nicaea; both of these were founded after Alexander the Great; but at a much earlier period the Greeks had established on the coast the colonies of Cius, Chalcedon, and Heraclea Pontica. All these rose to be flourishing places of trade, as also Prusa at the foot of Mt. Olympus (see BRUSA). The only other places of importance at the present day are Ismid (Nicomedia) and Scutari.

See G. Perrot, *Galatie et Bithynie* (1862); for an interesting account of Roman relations with the Christians in Bithynia see Pliny, *Correspondence with Trajan* (ed E. G. Hardy, 1889), introduction pp. 51-65; Epp. xcvi. (xcvii.) and xcvi. (xcviii.) and appendix, pp. 239-243.

BITLIS or **BETLIS**, the chief town of a vilayet of the same name in Turkey, situated at an altitude of 4,700ft., in the deep, narrow valley of the Bitlis Chai, a tributary of the Tigris. The main part of the town and the bazaars are crowded alongside the stream, while suburbs with scattered houses among orchards and gardens extend up two tributary streams. The houses are massive and well built of a soft volcanic tufa, and with their courtyards and gardens climbing up the hill-sides afford a striking picture. At the junction of two streams in the centre of the town is a fine old castle, partly ruined, which, according to local tradition, occupies the site of a fortress built by Alexander the Great. It is apparently an Arab building, as Arabic inscriptions appear on the walls, but as the town stands on the principal highway between the Van plateau and the Mesopotamian plain it must always have been of strategic importance. The bazaars are crowded, covered across with branches in summer, and typical of a Kurdish town. There are some fine old mosques and medresses. Pop (1927) 60,527. The climate is healthy and the thermometer rarely falls below 0° F, but there is a heavy snowfall and the narrow streets are blocked for some five months in the year.

A good road runs southward, passing after a few miles some large chalybeate and sulphur springs. Roads also lead north to Mush and Erzerum and along the lake to Van. Postal communication is through Erzerum with Trebizond. Tobacco of an inferior quality is largely grown, and the chief industry is the weaving of a coarse red cloth. Manna and gum tragacanth are also collected. Fruit is plentiful, and there are many vineyards close by. The Bitlis vilayet includes the Mush plain and the plateau country west of Lake Van, as well as a large extent of wild mountain districts on either side of the central town of Bitlis. The mountains have been little explored, but are believed to be rich in minerals; iron, lead, copper, traces of gold and many mineral springs are known to exist.

BITONTO (anc. *Butunti*), episcopal see, Apulia, Italy, province of Bari, 10m. W. by steam tramway from Bari. Pop. (1921), 26,841 (town); 31,698 (commune). Its fine Romanesque cathedral (1175-1200) has escaped damage from later restorations.

BITTER, KARL THEODORE FRANCIS (1867-1915), American sculptor, was born in Vienna on Dec. 6, 1867. After studying art there, in 1889 he removed to the United States, where he became naturalized. Among his principal works are: the Astor memorial gates, Trinity church, New York; "Elements Controlled and Uncontrolled," on the Administration building at the Chicago Exposition; a large relief, "Triumph of Civilization," in the waiting-room of the Broad street station of the Pennsylvania railway in Philadelphia; decorations for the Dewey naval arch in New York city; a sitting statue and a bust of Dr. Pepper, provost of the University of Pennsylvania; and the Villard and Hubbard memorials in the New York chamber of commerce. In 1911 he finished a model designed for the Henry Hudson monument. He was director of sculpture at the San Francisco Exposition (1912-16) and at the time of his death in New York (April 10, 1915) was president of the National Sculpture Society.

BITTERFELD, a town of Germany, in the Prussian province of Saxony, 26m N. of Leipzig by rail, on the river Mulde, and an important junction of railways from Leipzig and Halle to Berlin. Pop (1925) 19,336. Its manufactures include drain-pipes and machinery; there are several coal-mines in the vicinity. The town was built by a colony of Flemish immigrants in 1153. It was captured by the landgrave of Meissen in 1476, and belonged thenceforth to Saxony, until it was ceded to Prussia in 1815. Owing to its pleasant situation and accessibility, it has become a favourite residence of business men of Leipzig and Halle.

BITTERLING (*Rhodeus amarus*), a little carp-like fish of central Europe, belonging to the Cyprinid family. In it we have a remarkable instance of symbiosis. The genital papilla of the female acquires a great development during the breeding season and becomes produced into a tube nearly as long as the fish itself, this acts as an ovipositor by means of which the comparatively few and large eggs (3 millimetres in diameter) are introduced through the gaping valves between the branchiae of pond mussels (*Unio* and *Anodonta*), where, after being inseminated, they undergo their development, the fry leaving their host about a month later. The mollusc reciprocates by throwing off its embryos on the fish, in the skin of which they remain encysted for some time, the reproductive period of fish and mussel coinciding.

BITTERN, the name for wading birds, allied to the heron, from which they differ by their shorter neck, with its long, movable feathers in front, and their stouter build. Solitary and nocturnal, they haunt swamps and marshes, feeding on fish, insects and small quadrupeds. The common bittern (*Botaurus stellaris*) was formerly abundant in Britain, but became extinct during the 19th century. It has now re-established itself in the Norfolk Broads, and is found in most parts of the eastern hemisphere. The "booming" of the bittern during the breeding season is characteristic. When wishing to escape notice, the bird stands still, with bill directed upwards.

BY COURTESY OF THE NATIONAL ASSOCIATION OF AUDUBON SOCIETIES

THE BITTERN, A MARSH BIRD COMMONLY CALLED "STAKE DRIVER" BECAUSE OF THE PECULIAR CALL IT UTTERS DURING MATING SEASON

In this attitude, the dark streaks on the plumage render it invisible among the reeds at a short distance. The four or five olive-brown eggs are laid in a rude nest of reeds and flags. In courtship, it erects two tufts of feathers in the shoulder region. The American bittern (*B. lentiginosus*) is slightly smaller; it occurs in central and southern N. America.

BITTERN (from "bitter"), the mother liquor obtained from sea-water or brines after the separation of the sodium chloride (common salt) by crystallization. It contains various magnesium salts (sulphate, chloride, bromide and iodide) and is employed commercially for the manufacture of Epsom salts (magnesium sulphate) and bromine. The same term is applied to a mixture of quassia, iron sulphate, *cocculus indicus*, liquorice, etc., used in adulterating beer.

BITTERROOT (*Lewisia rediviva*), a North American plant of the purslane family (Portulacaceae), native to mountain regions from Montana to British Columbia and southward to Colorado, Arizona and southern California. Crowning its stout root is a thick perennial rootstock from which rise small fleshy leaves and short, jointed stalks each bearing a beautiful rose-red, cactus-like flower, 2 in. or more across. In early spring the flowers bloom in immense numbers in stony soil on ridges and in alpine valleys. The large starchy tap root was highly esteemed for food by the Indians. The plant became known to science from specimens collected by Meriweather Lewis (q.v.), of the Lewis and Clark expedition (1806-07), and the botanical genus *Lewisia* was named in his honor by Frederick Pursh (q.v.). The Bitterroot river and the Bitterroot mountains in Montana are named after this plant, which has been chosen the State flower.

BITTERS, aromatized and often alcoholic beverages containing a bitter substance or substances, used as tonics, appetizers or digestives. The bitterness is imparted by such substances as bitter orange rind, gentian, rhubarb, quassia, cascarilla, angostura, quinine and cinchona. Juniper, cinnamon, caraway, camomile, cloves and other flavouring agents are also employed in conjunction with the bitter principles, alcohol and sugar. Some bitters are prepared by simple maceration and subsequent filtration (see LIQUEURS), others by the more complicated distillation process. Those prepared by the latter process are the finer commercial articles. Bitters are usually sold under the name of the substance which has been used to give them the predominant flavour, such as orange, angostura, or peach bitters, etc. The alcoholic strength of bitters varies, but is generally in the neighbourhood of 40% of alcohol. Some bitters, although possessing tonic properties, may be regarded as beverages pure and simple, notwithstanding the fact that they are seldom consumed in an undiluted state; others again, are obviously medicinal preparations.

BITTERSWEET, a name for the woody nightshade (*Solanum Dulcamara*). (See NIGHTSHADE.) Also applied in the United States to *Celastrus scandens*, a woody vine, called more properly climbing bittersweet (q.v.).

BITUMEN, the name applied by the Romans to the various types of natural hydrocarbons, the word petroleum not being used in classical Latin. Classical and Biblical references to bitumens are of frequent occurrence. In Genesis xi. 3 we are told that "slime had they for mortar" and in Genesis xiv. 10 that the vale of Siddim "was full of slimepits," the word slime in the latter quotation appearing as bitumen in the Vulgate.

In the modern use of the word, largely owing to its commercial application, there is a tendency to restrict its popular meaning to the solid or semi-solid hydrocarbons, although in its widest sense it includes all the natural hydrocarbons. In the classification now generally accepted, but not, as yet, established by authority, gaseous hydrocarbons are, however, excluded.

Bitumens.	Liquid petroleum	Paraffin base. Mixed base. Asphaltic base.
	Native mineral waxes.	Ozokerite (called Ceresine when refined). Montan wax (extracted from peat).
	Native asphalts.	Vary from a pure solid bitumen to an impure bitumen containing a high percentage of sand, clay, etc.
	Asphaltites	Gilsonite } Characterized by a higher Glance pitch } fusing point than the Grahamite } asphalts.
Pyrobitumens.	Asphaltic Pyrobitumen.	{ Elaterite } Wurtzilite } Infusible and insoluble, Albertite } derived from petroleum. Impsonite } Oil shale. }
	Non asphaltic pyrobitumens.	{ Peat. } Lignite. } Infusible and Bituminous coal. } insoluble, de- Anthracite coal. } rived from veg- Lignitic & coal shales. } etable matter.

The solid bitumens are characterized by being fusible and largely soluble in carbon disulphide. Allied to, but distinct from the bitumens are the Pyrobitumens, a group of solid substances characterized by being infusible and insoluble, but which, on heating, generate or become transformed into bodies resembling bitumens in their solubility and physical properties.

In its various forms bitumen is one of the most widely distributed of substances. It occurs, though sometimes only in small quantities, in almost every part of the globe and throughout the whole range of geological strata, from the Laurentian rocks to the most recent members of the Quaternary Period. All the asphalts, asphaltites, and asphaltic pyrobitumens, with the exception of oil shale, have probably been derived from liquid petroleum, either by the evaporation of the lighter fraction under atmospheric conditions or by deeper seated metamorphism. A range of products similar to many of the native solid bitumens is obtained as residues on the distillation of various types of crude petroleum, these forming many of the "asphalts" and "bitumens" of commerce. There is still confusion as to the significance of these two words. (See ASPHALT.) (J. R.)

See Herbert Abraham, *Asphalts and Allied Substances* (New York, 1918); Percy E. Spielmann, *Bituminous Substances* (Berne, 1925).

BITUMINOUS SHALES: see ASPHALT.

BITURIGES (bit-oor'-gās), a Celtic people, according to Livy (v. 34) the most powerful in Gaul in the time of Tarquinius Priscus. At some period they split up into two branches—Bituriges Cubi and Bituriges Vivisci.

The Bituriges Cubi in Caesar's time acknowledged the supremacy of the Aedui, inhabited the departments of Cher and Indre, and partly that of Allier. Their chief town was Avaricum (Bourges). At the time of the rebellion of Vercingetorix (52 B.C.), Avaricum was taken by assault, and the inhabitants put to the sword. In the following year, the Bituriges submitted to Caesar, and under Augustus they were incorporated (28 B.C.) in Aquitania. Their district contained a number of iron works, and Caesar says they were skilled in driving galleries and mining.

The Bituriges Vivisci occupied the strip of land between the sea and the left bank of the Garonne, comprising the greater part of the modern department of Gironde. Their capital was Burdigala (Bordeaux), even then a place of considerable importance and a wine-growing centre. Pliny refers to both Cubi and Vivisci as *liberi*; i.e., they enjoyed some degree of independence.

See A. Desjardins, *Géographie historique de la Gaule romaine*, ii (1876-93); T. R. Holmes, *Caesar's Conquest of Gaul* (1899).

BITZIUS, ALBRECHT (1797-1854), best known by his pen name of "Jeremias Gotthelf," Swiss novelist, was born on Oct. 4, 1797, at Morat, where his father was pastor. He studied theology at Bern, took orders in 1820, and from 1832 till his death on Oct. 24, 1854, was pastor of the village of Lützelfliuh, in the Upper Emmenthal (between Langnau and Burgdorf). His first work, the *Bauernspiegel*, appeared in 1837. It purported to be the life of Jeremias Gotthelf, narrated by himself, and this name was later adopted by the author as his *nom de plume*. It is a living picture of Bernese (or, strictly speaking, Emmenthal) village life, marked by simplicity, humour, a high moral tone, and scrupulous truth to nature. It at once became very popular. His best known novel is *Uli der Knecht* (1841), of which an English translation was made by J. Firth, with notes by Ruskin, under the title of *Uli the Farm Servant* (1888). His other chief works include *Uli der Pächter* (1846; a sequel to *Uli der Knecht*); *Geld und Geist* (1842), portraying the patriarchal life of the rich peasant (1842; Eng. tr. 1866); *Jakobs, de Handwerksgesellen, Wanderungen durch Schweiz* (1847); *Zeitgeist und Berner Geist* (1852; these two dealing with the political questions of the day); *Erlebnisse eines Schuldenbauers* (1854), depicting the struggles of a peasant proprietor; and *Käthi die Grossmutter* (1847). He also wrote many short stories.

BIBLIOGRAPHY.—A complete edition of his works, in 30 vols., was published in 1855-58; another, in 24 vols., in 1916-29. In 1923 appeared a selection from this, in 14 volumes. His life has been written by A. Bartels (1902), G. Murt (1912; French), C. Manuel (1923) and others. See also studies by Ricarda Huch (1917), R.

Huniker and Ineichen (1920), and his correspondence with K. H. Hagenbach (1910).

BIVOUAC, originally meant a night-watch by a whole army under arms to prevent surprise. In modern military parlance the word is used to mean a temporary encampment in the open field without tents, as opposed to "billets" or "cantonment" on the one hand and "camp" on the other. Shelter in bivouac is usually improvised by stretching blankets or waterproof sheets on a support formed by sticks or branches driven into the ground. The use of bivouacs permits an army to remain closely concentrated for all emergencies and avoids the necessity for numerous wagons carrying tents. Constant bivouacs, however, are trying to the health of men and horses, and this method of quartering is never employed except when the situation demands concentration and readiness.

BIWA, a lake of South Japan having an area of 180 sq. m. which is about the size of the Lake of Geneva. It lies (35° 15' N. 136° 5' E.) in a zone of dislocation which cuts in a north-easterly to south-westerly direction across the entire width of the Japanese arc. The frontier between the Japanese invaders (the Yamato) and the aboriginal Ainu long lay about this zone. It was not until after the introduction of iron and the expulsion of the Japanese ruling house from South Korea in the latter half of the 7th century that the Japanese finally advanced beyond it into North Honshu. During the halt the Japanese capital was for strategic reasons removed from Kyushu to Kyoto, within a few miles of Lake Biwa, where it remained until 1868. Lake Biwa and its vicinity are rich in the historical associations and legends of Old Japan, and its beauty has been the theme of much Japanese poetry.

BIXIO, NINO (1821–1873), Italian soldier, was born on Oct. 2 1821. After numerous adventures at sea he returned to Italy in 1846, and joined the Giovine Italia. He fought through the campaign of 1848, became captain under Garibaldi at Rome in 1849, and in 1859 commanded a Garibaldian battalion. Joining the Marsala expedition in 1860, he turned the day in favour of Garibaldi at Calatafimi, was wounded at Palermo, but recovered in time to besiege Reggio in Calabria (Aug. 21 1860), and took part in the battle of Volturmo. Elected deputy in 1861, he endeavoured to reconcile Cavour and Garibaldi. In 1866 he covered the Italian retreat from Custoza. Created senator in February 1870, he was in the following September given command of a division during the movement against Rome, took Cività Vecchia, and participated in the general attack upon Rome Sept. 20 1870. He died of cholera at Achin bay in Sumatra *en route* for Batavia, whither he was leading a commercial expedition (Dec. 16, 1873).

See G. M. Trevelyan, *Garibaldi and the Thousand* (1909).

BIZERTA, a seaport of Tunisia, in 37° 17' N., 9° 50' E. Pop. (1926) 20,593. Next to Toulon, Bizerta is the most important naval port of France in the Mediterranean, in a commanding strategical position in the narrowest part of the sea, 714 m. E. of Gibraltar, 1,168 m. W.N.W. of Port Said, 240 m. N.W. of Malta, and 420 m. S. by E. of Toulon. It is 60 m. by rail N.N.W. of Tunis. The town is built on the shores of the Mediterranean at the point where the Lake of Bizerta enters the sea through a natural channel, the mouth of which has been canalized. The modern town lies almost entirely on the north side of the canal. A little farther north are the ancient citadel, the walled "Arab" town and the old harbour (disused). The present outer harbour covers about 300 acres and is formed by two converging jetties and a breakwater. The north jetty is 4,000 ft. long, the east jetty 3,300 ft., and the breakwater—which protects the port from the prevalent north-east winds—2,300 ft. long. The entrance to the canal is in the centre of the outer harbour. The canal is 2,600 ft. long and 787 ft. wide on the surface. Its banks are lined with quays, and ships drawing 26 ft. of water can moor alongside. At the end of the canal is a large commercial harbour, beyond which the channel opens into the lake—in reality an arm of the sea—roughly circular in form and covering about 50 square m., two-thirds of its waters having a depth of 30 to 40 ft. The lake contains the naval port and arsenal. The principal naval works are at Sidi Abdallah at the south-west corner of the lake and 10 m. from the open sea. Here is an enclosed basin

covering 123 acres with ample quayage, dry docks and everything necessary to the accommodation, repair, revictualling and coaling of a numerous fleet. Barracks, hospitals and waterworks have been built, the military town, called Ferryville, being self-contained. Railways from Bizerta to the Nefza mines will increase the commerce of the port. Fortifications have been built for the protection of the port.

The Lake of Bizerta (Arab, Tinja), abounds in excellent fish, especially mullets, the dried roe of which, called *botargo*, is largely exported. The western shore of the lake is low, and in many places is covered with olive trees to the water's edge. The south-eastern shores are hilly and wooded. A narrow and shallow channel leads from the western side of the lake into another sheet of water, the Lake of Ishkul, so called from Jebel Ishkul, a hill on its southern bank 1,740 ft. high. Ishkul is nearly as large as Bizerta, but is very shallow. Its waters are generally sweet.

Bizerta occupies the site of the ancient Tyrian colony, Hippo Zarytus or Diarrhytus, the harbour of which, by means of a spacious pier, protecting it from the north-east wind, was rendered one of the safest and finest on this coast. The town became a Roman colony, and was conquered by the Arabs in the 7th century. The place thereafter was subject either to the rulers of Tunis or of Constantine, but was noted for frequent revolts. It threw in its lot (c. 1530) with the pirate Khair-ed-Din, and subsequently received a Turkish garrison. Bizerta was captured by the Spaniards in 1535, but not long afterwards came under the Tunisian Government. Centuries of neglect followed, and the ancient port was almost choked up, though the value of the fisheries saved the town from utter decay. In 1890 a concession for a new canal and harbour was granted to a company, and five years later the new port was formally opened. Since then the canal has been widened and deepened, and the naval port at Sidi Abdallah created.

BIZET (ALEXANDRE CÉSAR LÉOPOLD) **GEORGES** (1838–1875), French musical composer, was born at Bougival, near Paris, Oct. 25, 1838, the son of a singing-master. He studied at the Paris Conservatoire under Halévy and in 1857 won the Grand Prix de Rome for a cantata called *Cloris et Clotilde*. After the three years spent in Rome, Bizet returned to Paris, where he achieved a reputation as a pianist and accompanist. His first opera, *Les Pêcheurs de perles*, was produced (Sept. 23, 1863) at the Théâtre Lyrique, but did not enjoy a very long run. It contains none the less some delightful music and some of its dances are now usually introduced into the fourth act of *Carmen*.

On June 3, 1865, Bizet married a daughter of his old master, Halévy. His second opera, *La Jolie Fille de Perth*, was produced at the Théâtre Lyrique on Dec. 26, 1867, and one number, the favourite and characteristic Bohemian dance, has been interpolated into the fourth act of *Carmen*. In his third opera *Djamileh* (Opéra Comique, May 22, 1872) Bizet returned to an oriental subject. In all these works Bizet was accused of Wagnerian tendencies, which was then a most serious condemnation in Parisian musical circles. But he won a great popular success with the incidental music which he wrote to Alphonso Daudet's drama, *L'Arlésienne*, produced in Oct. 1872.

Bizet's masterpiece, *Carmen*, was produced at the Opéra Comique on March 3, 1875. It was based on a version by Meilhac and Halévy of a study by Prosper Mérimée. In reconstructing the familiar story in dramatic form the authors produced one of the most striking and successful libretti in the whole range of opera. In this "book" Bizet found material exactly fitted for his romantic music, and the resulting opera, although at first coolly received in Paris, has long since taken its place, by universal consent in every operatic repertoire.

On June 3, three months after the production of *Carmen* in Paris, Bizet died of heart disease.

BJERKNES, VILHELM (1862–), Norwegian physicist, a son of Carl Anton Bjerknes, professor of mathematics in the University of Christiania (Oslo), was educated at the university of that city. At an early age he gave an experimental confirmation of his father's prediction, on theoretical grounds, of the remarkable apparent actions at a distance between pul-

sating and oscillating bodies in a fluid, and their analogy with electric and magnetic actions at a distance. From 1890-91 he studied electric waves at Hertz's Laboratory at Bonn in Germany, and in 1895, after carrying out much valuable work at Oslo (Christiania) and at Stockholm, where he was appointed lecturer in the university in 1893 and professor of mechanics and mathematical physics in 1895, he gave a complete theory of the phenomenon of electric resonance which has contributed much to the development of wireless telegraphy.

Bjerknes subsequently returned to hydrodynamics and particularly the problems of meteorology, in which he was supported by the Carnegie Institute of Washington. Two introductory volumes of a larger work, *Dynamic Meteorology and Hydrography*, were published in 1910-11, under the auspices of this institution. In 1917 he went to Bergen, where, as professor of physics, in the new Geophysic Institute there, he was the originator of an improved and more scientific weather service, afterwards controlled by his son and collaborator, Jakob Bjerknes (b. 1897), which occasioned a new view of cyclones and anticyclones. His papers on electric oscillations were published in *Annalen der Physik* (1891-95). In his *Vorlesungen über Hydrodynamische Fernkräfte nach C. A. Bjerknes' Theorie* (1900-02), he gave the first complete exposition of his father's discoveries, and in a later book *Die Kraftfelder* (1909), he stated the same theory in a generalized form according to methods of his own.

Vilhelm Bjerknes was elected vice president of the Congress of Scandinavian Geophysicists in 1918 and an honorary member of the Royal Institution in 1922.

BJÖRNEBORG: see **PORI**.

BJORNSON, BJORNSTJERNE (1832-1910), Norwegian poet, novelist and dramatist, was born at the farmstead of Björgen, in Kvikne, in Østerdal, Norway. In 1837 his father, who had been pastor of Kvikne, was transferred to the parish of Noeset, in Romsdal; in this romantic district the childhood of Björnson was spent. He matriculated at the University of Oslo in 1852, and soon began to work as a dramatic critic. In 1857 appeared *Synnøve Solbakken*, the first of his peasant-novels; in 1858 this was followed by *Arne*, in 1860 by *A Happy Boy*, and in 1868 by *The Fisher Maiden*. These are the most important specimens of his *bonde-fortællinger* or peasant-tales.

Björnson was anxious "to create a new saga in the light of the peasant," as he put it, and he thought this should be done, not merely in prose fiction, but in national dramas or *folke-stykker*. The earliest of these was a one-act piece, *Between the Battles*, written in 1855, but not produced until 1857. It was followed by *Lame Hulda* in 1858, and *King Sverre* in 1861, but these efforts were far excelled by the splendid trilogy of *Sigurd the Bastard*, which Björnson issued in 1862. This raised him to the front rank among the younger poets of Europe. His *Sigurd the Crusader* should be added to the category of these heroic plays, although it was not printed until 1872.

At the close of 1857 Björnson had been appointed director of the theatre at Bergen, a post which he held for two years, when he returned to the capital. From 1860 to 1863 he travelled widely throughout Europe. Early in 1865 he became manager of the Oslo theatre, and brought out his popular comedy of *The Newly Married* and his romantic tragedy of *Mary Stuart in Scotland*. Although Björnson has introduced into his novels and plays songs of extraordinary beauty, he was never a very copious writer of verse; in 1870 he published his *Poems and Songs* and the epic cycle called *Arnliot Gelline*; the latter volume contains the magnificent ode called "Bergliot," Björnson's finest contribution to lyrical poetry. In 1871 he began to supplement his journalistic work as a radical agitator by delivering lectures in the northern countries. His new departure as a dramatic author began with *A Bankruptcy* and *The Editor* in 1874, social dramas of a realistic cast.

The poet now settled on his estate of Aulestad in Gausdal. In 1877 he published another novel, *Magnhild*—an imperfect production, in which his ideas on social questions were seen to be in a state of fermentation, and gave expression to his republican sentiments in the polemical play called *The King*, to a later

edition of which he prefixed an essay on "Intellectual Freedom," in further explanation of his position. *Captain Mansana*, an episode of the war of Italian independence, belongs to 1878. Extremely anxious to obtain a full success on the stage, Björnson concentrated his powers on a drama of social life, *Leonarda* (1879), which raised a violent controversy. A satirical play, *The New System*, was produced a few weeks later; but none of these plays of his second period (except *A Bankruptcy*) pleased on the boards, and when once more he produced a social drama, *A Gamble*, in 1883, he was unable to persuade any manager to stage it, except in a modified form, though this play gives the full measure of his power as a dramatist. In the autumn of the same year he published a mystical or symbolic drama *Beyond our Powers*, dealing with the abnormal features of religious excitement with extraordinary force; this was not acted until 1899, when it achieved a great success.

Meanwhile, Björnson's political attitude had brought upon him a charge of high treason, and he took refuge in Germany, returning to Norway in 1882. Convinced that the theatre was practically closed to him, he turned back to the novel, and published in 1884, *Flags are Flying in Town and Port*, embodying his theories on heredity and education. In 1889 he printed another long and still more remarkable novel, *In God's Way*, which is chiefly concerned with the same problems. The same year saw the publication of a comedy, *Geography and Love*, which continues to be played with success. A number of short stories, of a more or less didactic character, dealing with startling points of emotional experience, were collected in 1894; among them those which produced the greatest sensation were *Dust*, *Mother's Hands*, and *Absalom's Hair*. Later plays were a political tragedy called *Paul Lange and Tora Parsberg* (1898), a second part of *Beyond our Powers* (1895), *Laboremus* (1901), *At Storhove* (1902), and *Daglaunet* (1904).

Björnson was one of the original members of the Nobel committee, and was awarded the Nobel prize for literature in 1903. He died on April 26 1910.

See Björnson's *Samlede Digter-Verker* (Christiania and Copenhagen, 1910-20); *The Novels of Bjornstjerne Bjornson* (1894), etc. edited by Edmund Gosse; G. Brandes, *Critical Studies* (1899); E. Tissot, *Le drame norvégien* (1893); C. D. af Wirsén, *Kritiker* (1901); Chr. Collin, *Bjornstjerne Bjornson* (German ed., 1903); and B. Halvorsen, *Norsk Forfatter Lexikon* (1885). His *Poems and Songs* have been translated by A. Hubbell Palmer (1915).

BLACHE, VIDAL DE LA (1845-1918), French geographer, was born in Pézénas, Hérault, on Jan. 22, 1845. He was educated at the École Normale Supérieure in Paris, and entered upon the study of geography by way of that of history. The relations between geographical causes and historical effects were with him the subject of a life-study, the results of which are seen in one of his best-known works, the *Tableau Général de la Géographie de France* prefixed to Lavis's *Histoire de France* (1903) and later republished separately; but he always refrained from pressing the theory of geographical "control" to an extreme. He joined the French school at Athens in 1867. From 1872 to 1877 he was in charge, latterly as professor, of the department of history and geography at Nancy; from 1877 to 1898 he taught geography in the higher grades at the École Normale Supérieure, and from 1898 to 1909 he held the chair of geography in the Faculté des Lettres at Paris. He lectured widely, and among his publications is the monumental *Atlas Général: Histoire et Géographie*, first published in 1894. He founded in 1891, and edited until his death, the periodical *Annales de Géographie*, and contributed constantly to its pages. He died at Tamaris-sur-Mer (Var) on April 5, 1918.

BLACK, ADAM (1784-1874), Scottish publisher, founder of the firm of A. and C. Black, the son of a builder, was born in Edinburgh on Feb. 20, 1784, and died there on Jan. 24, 1874. He began business for himself in Edinburgh in 1808. By 1826 he was recognized as one of the principal booksellers in the city; and a few years later he was joined in business by his nephew Charles. The two most important events connected with the history of the firm were the publication of the 7th, 8th and 9th editions of the *Encyclopædia Britannica*, and the purchase of the stock and copyright of the Waverley Novels. The copyright of the *Encyclopædia* passed into the hands of Adam Black and a few friends in 1827.

In 1851 the firm bought the copyright of the Waverley Novels for £27,000; and in 1861 they became the proprietors of De Quincey's works. Adam Black was twice lord provost of Edinburgh and represented the city in parliament from 1856 to 1865. He was succeeded by his sons, who removed their business in 1895 to London.

See *Memoirs of Adam Black*, edited by Alexander Nicholson (2nd ed., Edinburgh, 1885).

BLACK, JEREMIAH SULLIVAN (1810–1883), American lawyer and statesman, was born in Stony Creek township, Somerset county, Pa., on Jan. 10, 1810. He was largely self-educated, and before he was of age was admitted to the Pennsylvania bar. He gradually became one of the leading American lawyers, and in 1851–57 was a member of the supreme court of Pennsylvania (chief-justice 1851–54). In 1857 he entered President Buchanan's cabinet as attorney-general of the United States, and in this capacity successfully contested the validity of the "California land claims." From Dec. 17, 1860 to March 4, 1861, he was secretary of State. Perhaps the most influential of President Buchanan's official advisers, he denied the constitutionality of secession, and urged that Fort Sumter be properly reinforced and defended. "For . . . the vigorous assertion at last in word and in deed that the United States is a nation," says James Ford Rhodes, "for pointing out the way in which the authority of the Federal Government might be exercised without infringing on the rights of the States, the gratitude of the American people is due to Jeremiah S. Black." After 1862 he devoted himself almost exclusively to law practice, appearing in important cases before the supreme court. After the Civil War he vigorously opposed the Congressional plan of reconstructing the late Confederate states, and himself drafted the message of President Johnson, vetoing the Reconstruction Act of March 2, 1867. Black was also for a short time counsel for President Andrew Johnson, in his impeachment trial, and for William W. Belknap (1829–90), secretary of war from 1869 to 1876, who in 1876 was impeached on a charge of corruption; and with others he represented Samuel J. Tilden before the Electoral Commission (*q v*) in 1877. He died at Brockie, Pa., on Aug. 19, 1883.

See *Essays and Speeches of Jeremiah S. Black, with a Biographical Sketch* (1885), by his son, C. F. Black.

BLACK, JOSEPH (1728–1790), Scottish chemist and physicist, was born at Bordeaux, where his father—a native of Belfast but of Scottish descent—was engaged in the wine trade. He was educated at Belfast, and at Glasgow university. There he had William Cullen for his instructor in chemistry, and the relation between the two soon became that of professor and assistant rather than of master and pupil. In the thesis *De humore acido a cibus orto, et magnesia alba*, which he presented for his doctor's degree in 1754, he described his investigations in causticization, and anticipated Lavoisier and modern chemistry by indicating the existence of a gas distinct from common air, which he detected by using the balance. A fuller account of them was read before the Medical Society of Edinburgh in June 1755, and published in the following year as *Experiments upon magnesia, quicklime and some other alkaline substances*.

It is curious that Black left to others the detailed study of this "fixed air" he had discovered. Probably the explanation is pressure of other work. In 1756 he succeeded Cullen as lecturer in chemistry at Glasgow, and was also appointed professor of anatomy, though that post he was glad to exchange for the chair of medicine. He also practised as a physician. Moreover, his attention was engaged on studies which ultimately led to his doctrine of latent heat. He noticed that when ice melts it takes up a quantity of heat without undergoing any change of temperature, and he argued that this heat, which, as was usual in his time, he looked upon as a subtle fluid, must have combined with the particles of ice and thus become latent in its substance. This hypothesis he verified quantitatively by experiments performed at the end of 1761. In 1764, with the aid of his assistant, William Irvine (1743–87), he further measured the latent heat of steam, though not very accurately. This doctrine of latent heat he taught in his lectures from 1761 onwards, and in April 1762 he described

his work to a literary society in Glasgow. But he never published any detailed account of it, so that others, such as J. A. Deluc, were able to claim the credit of his results. In the course of his enquiries he also noticed that different bodies in equal masses require different amounts of heat to raise them to the same temperature, and so founded the doctrine of specific heats; he also showed that equal additions or abstractions of heat produced equal variations of bulk in the liquid of his thermometers. In 1766 he succeeded Cullen in the chair of chemistry in Edinburgh. He died in Edinburgh on Dec. 6, 1799 (not on Nov. 26 as stated in Robison's life).

Apart from the work already mentioned he published only two papers during his lifetime—"The supposed effect of boiling on water, in disposing it to freeze more readily" (*Phil. Trans.*, 1775), and "An analysis of the waters of the hot springs in Iceland" (*Trans. Roy. Soc. Ed.*, 1794).

After his death his lectures were written out from his own notes, supplemented by those of some of his pupils, and published with a biographical preface by his friend and colleague, Professor John Robison (1739–1805), in 1803 as *Lectures on the Elements of Chemistry, delivered in the University of Edinburgh*.

BLACK, WILLIAM (1841–1898), British novelist and journalist, was born at Glasgow on Nov. 9, 1841, and died at Brighton on Dec. 10, 1898. He joined the staff of the *Morning Star* in London, and during the war between Prussia and Austria in 1866 acted as war correspondent, and was taken prisoner. Later Black served on the *Daily News*, and for some time edited the *Examiner*.

His first novel, *James Merle*, published in 1864, was a complete failure; his second, *Love or Marriage* (1868), attracted but very slight attention. In *Silk Attire* (1869) and *Kilmeny* (1870) marked a great advance on his first work, but in 1871 *A Daughter of Heth* suddenly raised him to the height of popularity, and he followed up this success by a string of favourites. Among the best of his books are *The Strange Adventures of a Phaeton* (1872); *A Princess of Thule* (1874); *Madcap Violet* (1876); *Macleod of Dare* (1878); *White Wings* (1880); *Judith Shakespeare* (1884); *White Heather* (1885); *Donald Ross of Heimra* (1891); and *Wild Erin* (1898). Black's best stories are those which are laid amid the breezy mountains of his native land, or upon the deck of a yacht at sea off its wild coast.

BLACK is now technically classified as a colour, being a terminal member of the so-called achromatic series of colours, ranging through a scale of greys to white. From the psychological standpoint black is as positive a phenomenon as any other colour, and cannot be identified with the absence of visual consciousness. It is also a mistake to regard black as an accompaniment of non-stimulation of the visual sense organs, since the normal result of this condition is a variable grey. In order to secure a true black either simultaneous or successive contrast is required, involving concomitant excitation of an outlying retinal area or prior excitation of the same area, respectively.

See *Psychological Review*, vol. xxxii., p. 248, and vol. xxvi., p. 498.

BLACK AND YELLOW TRAIL, a highway extending from Chicago, Ill., to Yellowstone park by way of the Black Hills and the Bad Lands of South Dakota. It is about 1,570 m. in length. Paved and improved through Wisconsin, the balance

is graded and improved with some dirt stretches in Minnesota, South Dakota and Wyoming. This road passes through Cody, Wyo., and is often spoken of as the "Cody Way." It is the shortest route from the Great Lakes to Yellowstone park. Wind Cave National park, with an area of 10,522 ac, lies in its path, while Milwaukee, Portage, Rapid City, Deadwood and Newcastle are some of the cities through which it passes.

BLACK APE, a black, short-tailed, long-faced macaque inhabiting Celebes, and forming a genus by itself, *Cynopithecus niger*. The nostrils open obliquely some distance from the end of the snout, and the head carries a long crest. (See PRIMATES.)

BLACK ASSIZE, a pestilence which raged in Oxford following the conclusion of the assizes on July 6, 1577. In five weeks some 300 persons are said to have succumbed to the sickness. Among them were the sheriff and a number of the jurors and court officials, which lent support to the theory that the pestilence was a manifestation of Divine indignation at an unjust sentence of the court. It was also noticed that the plague passed by the women and children, the poor and the doctors—a further reason for fastening the blame on the assizes.

BLACKBALL, a token used for voting by ballot against the election of a candidate for membership of a club or other association. White and black balls were used to represent votes for and against a candidate for such election. The rules of most clubs provide that a stated proportion of "blackballs" shall exclude candidates proposed for election, and the candidates so excluded are said to have been "blackballed"; but the ballot (*q.v.*) is now usually conducted either by voting papers or by balls cast into different compartments of a ballot-box.

BLACK BEAR TRAIL, a highway connecting Quebec and Ontario, Canada, with Miami and St. Petersburg, Florida. It has a total length of 1,950m. The road is paved from Quebec to North Carolina, and then again through Florida. Beginning at Montreal, it first follows the St. Lawrence river and then passes through the Adirondacks and the Catskill mountains Plattsburg, Ticonderoga, Albany, West Point, Bear Mountain, Gettysburg, Harper's Ferry, Staunton, Natural Bridge, Roanoke, Augusta and Jacksonville are some of the places along this route

BLACK BELT, a part of the southern United States, extending from central South Carolina, across central Georgia, through Alabama and Mississippi, so called because it is the area of greatest density of negro population. The Black Belt is slowly moving southward and westward into Louisiana, Arkansas and Texas. This is a country of large rice and cotton plantations. More than half of its population is negro. In the country districts living conditions and returns for labour are poor, with a greater tendency toward poverty with its shiftlessness and isolation than is found in the cities. Since 1865 there has been a steady migration from the farms to the towns. Since 1914 negroes have moved northward and westward in increasing numbers, largely because of droughts, floods, the attack of the boll weevil on the cotton and because of higher wages and better conditions in the north and west.

BLACKBERRY or **BRAMBLE**, a prickly, fruit-bearing shrub known botanically as *Rubus fruticosus* (family Rosaceae), a native of the north temperate region of the Old World, and abundant in the British Isles as a copse and hedge-plant. It is characterized by its prickly stem, leaves with usually three or five ovate, coarsely toothed stalked leaflets, many of which persist through the winter, white or pink flowers in terminal clusters, and black or red-purple fruits, each consisting of numerous succulent drupels crowded on a dry conical receptacle. It is a most variable plant, exhibiting many more or less distinct forms, which are regarded by different authorities as sub-species or species. In North America, several forms derived from native species, chiefly *Rubus allegheniensis* or *nigrobaccus*, are extensively cultivated

for their excellent fruit which is marketed fresh and used also for canning.

BLACKBIRD, name given to a bird originally known as ouzel (*q.v.*), though this has since been transferred to other species.

The blackbird (*Turdus merula*) is a close relative of the thrush (*q.v.*). It is one of the commonest of British birds. The males, which are said to preponderate, are recognizable by their black plumage and orange bill. The females are more thrushlike, being a dusky brown and the beak is also dark.

The blackbird is an early nester, often beginning to lay in February, and raises two broods in the year. The nest, usually placed in bushes or hedgerows, is made of hay and coarse grass, neatly interwoven and lined with hair and fine grass. The eggs, 3 to 5 in number, are pale blue-green, mottled with brown. The young resemble the female in colour. Its food consists of fruits, buds, insects, worms, snails, etc. The song is mellow and flutelike, and by some people is preferred to that of the thrush.

The blackbird is widely distributed over Europe and Asia, and, despite occasional raids on fruit-trees, is, on the whole, a beneficial species.

For the North American "blackbirds," see GRACKLE.

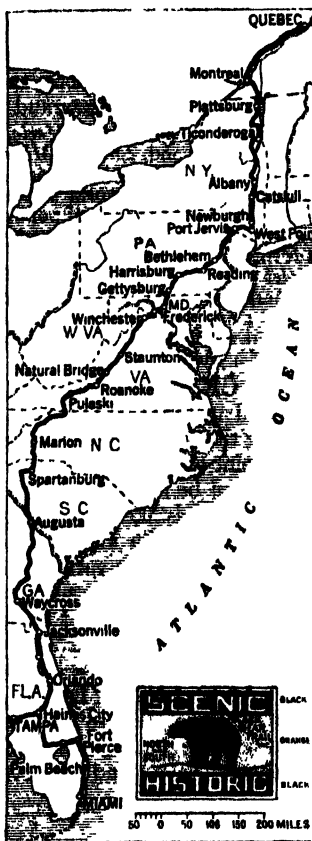

BLACKBIRD, RED-WINGED (*Agelaius phoeniceus*), a common North American bird, breeding from the Gulf of Mexico northward. The feathers of the male are black, tipped with rust-colour in winter, the wing-coverts being scarlet and buff. The female is brownish black above, and white streaked with black below, with the wing-coverts tinged with red. The bird is gregarious and possesses a liquid song and a shrill alarm note.

There are several subspecies, like the Sonoran, and San Diego red-wing. The bicoloured blackbird (*A. gubernator californicus*) is found in coastal Oregon and California; the tricoloured blackbird (*A. tricolor*), in the valleys of Oregon, California and Lower California.

Other species are the tawny-shouldered red-wing (*A. humilis*) of Cuba, and the yellow-shouldered red-wing (*A. xanthomus*) of Porto Rico.

BLACK BODY. The term black is commonly applied to any substance, such as coal or pitch, which absorbs nearly all the light falling on it and reflects very little. Lampblack or smoke-black consisting of very fine particles of carbon is usually taken as a typical example of a black substance. The majority of black substances owe their blackness to the presence of particles of carbon embedded in a binding medium, but reflect some light at the surface when smooth or polished. For scientific experiments in which complete absorption of the incident light is required, reflection at the surface must be avoided as far as possible. For this reason the internal surfaces of optical instruments, such as telescopes and cameras, are coated with a "dead-black" varnish, having a matt surface, to eliminate internal reflections which would obscure or fog the image.

In the case of visible light, a very small defect of perfect blackness can be detected readily by eye, but the visible rays form a very small proportion of the total radiation from any source of artificial light, and are completely absent in the case of any radiator at a temperature below a red heat. It cannot be assumed that surfaces which appear black to the eye and are practically perfect absorbers of visible light, are equally perfect absorbers of the invisible rays. Receiving instruments for detecting or measuring radiation, such as the thermopile or bolometer (see HEAT), depend for their accuracy on the completeness of the absorption of all radiation over a range of wave-length about a hundred times greater than that of visible light. The sensitive receiving surfaces of such instruments are necessarily metallic, and would be very bad absorbers of radiation. They are accordingly coated with a film of smoke-black or platinum-black to render the absorption as complete as practicable. An absorption equivalent to 98% of the incident radiation may thus be obtained under favourable conditions, but it is very difficult to estimate the percentage defect and to make sure that it is the same for all wavelengths. Some allowance is usually made for defective absorption in modern experiments, but it remains one

of the chief sources of uncertainty in accurate measurements. The condition of complete absorption cannot be met satisfactorily except by the adoption of the "black body" principle which has long been recognized as essential to the construction of a source of radiation possessing the characteristics of definite intensity and quality.

The theory of the black body as a perfect absorber is extremely simple. The apparatus consists merely of an aperture in the side of an otherwise light-tight chamber, the inside of which is blackened. Any radiation entering through the hole is scattered and absorbed by repeated reflection so that an infinitesimal fraction only could possibly escape. It is easy to convince oneself of the perfect blackness thus secured by removing the lens from a box camera and covering part of the aperture with a card painted with the best dead-black. The uncovered part of the aperture will appear of a much higher order of blackness than the most perfect dead-black coating procurable. The advantage of the method lies in the fact that the blackness thus secured is equally perfect for all wavelengths owing to the complete elimination of surface reflection at the aperture.

The practical application of the principle to the construction of a perfect receiver is not quite so easy. With a simple chamber as above described, the radiation entering through the aperture would be scattered over the inner surface and could not easily be collected and measured. The experimental difficulties of this problem cannot be discussed here but are illustrated in the article on HEAT. The application of the same principle to the construction of sources of radiation, also termed "black bodies," is described in the same article, but it will be well to explain here how the apparent misnomer "black" has come to be applied to a body emitting radiation.

It follows from the theoretical reasoning of Balfour Stewart (1858) and Kirchhoff (1859), based on the equilibrium of temperature, that a body capable of absorbing radiation perfectly at any temperature must be equally perfect in the emission of radiation. Further it follows that the intensity of radiation inside a hollow chamber at a uniform temperature, can depend only on the temperature, is the maximum possible at the given temperature, and is independent of the form of the chamber or of the materials of which it is composed. Chambers of this kind, provided with suitable heating appliances and with apertures for the emission of the internal radiation, are commonly termed black bodies and are employed as sources of radiation of definite quality and intensity. The radiation they emit is the same as that of a perfectly black surface at the same temperature and is often called "black" radiation. The black-body temperature of a source like the sun is the temperature at which a black body would emit radiation of the same intensity. (H L C)

BLACK BUCK (*Antelope cervicapra*), the Indian antelope, the sole species of its genus. This antelope stands about 32 in. high at the shoulder; the general hue is brown deepening with age to black; chest, belly and inner sides of limbs pure white, as are the muzzle and chin, and an area round the eyes. The horns are long, ringed, and form spirals with three to five turns. The doe is smaller and yellowish-fawn above. These antelopes frequent grassy districts and are found in herds (see ANTELOPE).

BLACKBURN, COLIN BLACKBURN, BARON (1813-1896), British judge, was born in Selkirkshire, and educated at Eton and Trinity college, Cambridge. He edited the eight volumes of the Ellis and Blackburn reports, and had a considerable commercial practice, but was unknown to the general public when he was promoted to a judgeship by Lord Campbell in 1859. "Who is Mr. Blackburn?" enquired *The Times*, but Blackburn proved one of the soundest lawyers on the bench, and when he went to the court of appeal in 1876 was considered the highest authority on common law. In the same year he was made a lord of appeal. Blackburn wrote a standard book on *The Law of Sales*. See E. Manson, *Builders of Our Law* (1904).

BLACKBURN, HELEN (1842-1903), British suffragist, was born at Knightstown, Valencia Island, Ireland, on May 25, 1842, the daughter of Bewicke Blackburn (1811-1897), a well-known engineer, who settled in London in about 1859. Helen

Blackburn was secretary of the central committee of the National Society for the Promotion of Women's Suffrage from 1874-95; sole editor of *The Englishwoman's Review* from 1881-90, and author of *Women's Suffrage: a Record of the Movement in the British Isles* (1902), which is the standard work on the subject. She left her library on questions connected with women to Girton college, Cambridge, England.

BLACKBURN, JOSEPH (c. 1700-1760), American portrait-painter, probably came from England, landing in New York and going almost immediately to Boston, where most of his work was done. It was not until 1920 that his Christian name was definitely known. No record of his birthplace or antecedents has been found; nor is there any knowledge of his connections in America or where and when he died. For many years he has been called Jonathan B., all his paintings being signed "J" or "I." His patrons came mainly from important early American families, including the Apthorps, Bowdoin, Bethunes, Bulfinches, Ervings, Faneuils, Phillips and Winslows of Boston; the Atkinsons, Cutts, Warners and Wentworths of Portsmouth; and the Bours and Brown families of Newport. His work, in treatment and method of painting costume, resembles that of Thomas Hudson, who may have been his master, and to some extent that of Joseph Highmore. It is inferior to the work of Robert Feke, his contemporary, but he surpasses Smybert in decorative quality and truthful drawing. Blackburn's influence was felt by Copley, then in his formative period; and until recently much of his work has been attributed to Copley. More than 80 portraits by him are now known to exist, most of them owned by private individuals; the remainder scattered among museums of art, colleges and historical institutes. Two are in the Metropolitan Museum in New York city; others in the art museums of Cleveland, Worcester, Boston and Brooklyn.

BLACKBURN, municipal, county, and parliamentary borough of Lancashire, England, 24½m north-northwest of Manchester, served by the LMS railway, with several lines from all parts of the county. Pop. (1921) 126,643. It lies in the valley of a stream called in early times the Blackeburn, but now known as the Brook. The parish church of St. Mary (now the cathedral) is on a site which seems to have had associations with early Christianity. Blackburn was for some time the chief town of a district called Blackburnshire, and as early as the reign of Elizabeth ranked as a flourishing market town. About the middle of the 17th century it became famous for its "checks" which were afterwards superseded by a similar linen-and-cotton fabric known as "Blackburn greys." In the 18th century the ability of the townspeople fostered its cotton industry and James Hargreaves invented his spinning jenny here about 1764. Coal, lime and building-stone abound in the neighbourhood, factors which helped the rapid development of the town during the last century.

The cotton industry employs thousands of operatives, especially women, the iron trade is very considerable, and many are engaged in the making of machines; a former woollen manufacture is almost extinct. Blackburn's specialty in the cotton industry is weaving. Many men are also employed in the local collieries. There is an Elizabethan grammar school housed in modern buildings (1884), and a fine technical school. The Corporation park and Queen's park are well laid out. An electrical generating station was opened in 1921, and by 1924, 27 of the large textile mills had adopted electric power. The period 1918-22 saw extensions in the town and the rise of new public buildings. New parishes were formed in the borough in 1914 and 1922. Blackburn is now a separate diocese, carved out of that of Manchester. The town received a charter of incorporation in 1851. The county borough was created in 1888. The parliamentary borough, which returns two members, is co-extensive with the municipal Area 7,420 acres.

BLACKBURNE, FRANCIS (1782-1867), lord chancellor of Ireland, was born at Great Footstown, Co. Meath, Ireland, on Nov. 11, 1782, educated at Trinity college, Dublin, and called to the English bar in 1805. He practised with success. Called to the Irish bar in 1822, he vigorously administered the Insurrection Act in Limerick for two years. In Ireland (1826) he became serjeant-at-law, attorney-general (1830 and 1841), master of the rolls

(1842), chief justice of the queen's bench (1846), lord chancellor (1852 and 1866), lord justice of appeal (1856). He prosecuted O'Connell and presided at the trial of Smith O'Brien. He died on Sept. 17, 1867.

BLACKCAP (*Sylvia atricapilla*), a small warbler (q.v.), notable for the beautiful song and black cap of the male, the female having the top of the head brown. The rest of the plumage in both sexes is grey. The blackcap is a summer visitor to northern Europe. The male often helps to incubate the eggs and may betray the nest by singing while sitting.

BLACKCOCK (*Lyrurus tetrix*), a bird of the family *Tetraonidae*, or grouse, the female of which is known as the greyhen. In size and plumage the two sexes offer a striking contrast, the male weighing about 4lb., its plumage, for the most part, of a rich glossy black, shot with blue and purple, the lateral tail feathers curved outwards so as to form a fan-like crescent, and the eyebrows bright vermilion and destitute of feathers. The female weighs only 2lb., its plumage is of a russet brown colour, irregularly barred with black, and its tail feathers are but slightly forked. The males are polygamous, and, during the spring, assemble on definite display-grounds, where they display and fight fiercely for possession of the females. The nest, composed of a few stalks of grass, is on the ground, and the female lays from six to ten eggs of a dirty yellow colour, speckled with dark brown. She hatches and rears her brood alone. The plumage of both sexes is at first like that of the female. The blackcock is distributed over the highland districts of northern and central Europe, and parts of Asia. It is abundant in the Scottish Highlands, where the female is called grey hen.

BLACK COUNTRY, THE, name applied to a district of the English Midlands including south Staffordshire with parts of Worcestershire and Warwickshire. The name is due to the numerous collieries and furnaces, and the desolation of scenery and agglomeration of houses consequent upon the mining of coal, ironstone and clay and dependent industries. The district is intersected by canals now mostly derelict, and by numerous branches of the G.W.R. and L.M.S.R. For localization of industries see BIRMINGHAM, WOLVERHAMPTON, WALSALL, etc.

BLACK DIAMOND HIGHWAY, THE, extends from Truro, Nova Scotia, to Port Hawkesbury, Sydney and Glace bay on Cape Breton island. It is about 223m. long and mostly good gravel road, broken by ferry across the Strait of Canso from Mulgrave on the mainland to Port Hawkesbury. Glasgow and Antigonish lie along this interesting route.

BLACK DROP, in astronomy, an apparent distortion of the planet Mercury or Venus at the time of internal contact with the limb of the sun at the beginning or end of a transit. It has been in the past a source of much perplexity to observers of transits, but is now understood to be a result of irradiation, produced by the atmosphere or by the aberration of the telescope.

BLACK EARTH AREA (Central), an administrative unit in Russia created by the Soviet Government in May 1928. It consists chiefly of the provinces of Voronezh, Kursk, Tambov and Orel, with part of the province of Tula. The creation of this province is in pursuance of the Russian Government's policy of trying to organize administrative units on the basis of their economic background. The Steppe Black Earth or Tchernozem, characteristic here, occurs over deposits of many kinds and ages, in a more or less continuous belt from Manchuria through Siberia to South Russia, Rumania, Hungary, Moravia and Bohemia. These regions have a high temperature and strong evaporation in summer with consequent desiccation of the soil, and, in winter, prolonged soil frost. During the winter, water accumulates and provides for a luxuriant spring crop of grass, the strong root systems of which supply organic matter and thus a soil is formed

having a humus content varying from 6% to 12% or more. When this belt lies on the loess (q.v.) the mobility of water in that formation favours the development of black earth, which under these circumstances spreads into less strictly arid areas. During the intense summer evaporation, the water accumulated in winter rises to the drying upper layers of the soil, and gypsum and calcium carbonate are deposited in distinct horizons, at various depths; the gypsum usually lies beneath the calcium carbonate stratum. The soil is loose in texture, very crumbly and of a deep black colour; the humus content decreases from above downwards, and humus layers 70 to 100 cm. thick are common. The lower soil (A₂ of the Russian investigators) is irregularly coloured, being usually light or yellowish brown, with dark veins and patches. The humus layer merges into bedrock in the lower layer of the soil without any sharp division.

In the Central Black Earth area of Russia, the climate is continental (av. Jan. temp. -8°C to -9°C , av. July temp. $+20^{\circ}\text{C}$ to $+22^{\circ}\text{C}$). The frost in winter is severe, the rivers are ice-bound from 110 to 120 days, and there is much snow. The rainfall, averaging about 500 mm. is sufficient for the local vegetation. The high summer insolation and the severe winter frost retard the decay of the humus. To the north is much grey forest soil, while to the south-east are a few patches of the salted soil so characteristic of the Lower Volga area. Along the river courses are sandy and alluvial soils. To the east of the Don river is a plain not more than 200 metres above sea-level, while the west is part of the Central Russian plateau rising to 500 metres. The prevailing character of the area is level plain, deeply entrenched by ravines and river valleys, the slopes of which are everywhere forest covered, so that steppe alternates with forest (lyessosteppe), though in the south the steppe is continuous. In the central course of the Don and its tributaries are chalk outcrops and in the central Don area high white chalk pillars appear. The prefix "Byel" (white) or "Myel" (chalk) is often given to the picturesque settlements in these areas, e.g., Byelgorod, Byelpolye, Byelgorye, Myelovaya.

The area is 195,000 sq km. and every bit of suitable land is cultivated. Of the population of 11,600,400 (1927), no fewer than 10,450,200 were engaged in agriculture, but in spite of this and of the fertility of the tchernozem, the harvest is insufficient for the needs of the people, and many go as seasonal labourers to other provinces, while others are occupied in koustar (peasant) industries, especially the manufacture of hempen rope and string. The standard of life is low, and miserable hovels without chimneys and with earthen floors are common. The three-field system is general and the transition to grass and root-crop cultivation and to the four-field system is slow. War and famine decreased fertility and reduced harvests, undermined the stamina of the people, diminished live stock (and consequently manure), horses by 50%, working cattle, sheep and pigs even more; and prevented renewal of agricultural implements. In 1926 the number of livestock was still markedly less than in 1913. The area sown in 1926 was about 80% of that in 1913 and the harvest per acre was much less. In a drought area the vegetation period is important, and varies for different crops. Rye, buckwheat, flax, millet and barley need 100 days or less, summer wheat and oats 105 days or more, while maize and potatoes may need 150 days. The chief crops are rye, millet and oats. Other crops are summer wheat and potatoes, hemp (especially in Voronezh, Orel and Kursk), sunflower seed (especially in Voronezh) and sugar beet in the southern region, where beekeeping is also very successful. Fruit is cultivated to some extent in the south and centre, the north-west corner lies beyond the northern limit of cherry production and the north-east beyond that of pear production. The north-west of the area has a good supply of timber and sawmilling is extensively carried on, but much of the remaining area is markedly deficient in timber. Factory industries are little developed and are mainly agricultural, e.g., sugar beet factories in Kursk and Voronezh, oil pressing from sunflower seeds in Voronezh and Tambov, while flourmilling is widespread, mainly dependent on wind. The electrification of the area is proceeding very slowly.

As regards mineral wealth, the marked magnetic needle anomaly has led to the recent discovery at a depth of 160 to 180 metres of iron ore in the Kursk and Shchigry areas, and this may result in industrial developments here. There are also phosphorite regions extending from Orel to Shchigry, and in the Morshansk area. Lipetsk is noted for its mineral springs and for the deposits of iron to the north-west of the town. Communications by rail, river and road are better than in many other districts of Russia, and several towns have grain elevators. The chief towns (*q v.*) are Voronezh, the administrative centre, Tambov, Orel, Kursk, Byelgorod, Lipetsk and Elets. The population is mainly Great Russian, though in the south-west there is a high proportion of Ukrainians, who demand to be treated as a national minority, and of Mordvins near Penza.

BLACK-EYED SUSAN. A North American species of cone-flower (*Rudbeckia hirta*), called also yellow daisy, native to dry open grounds from Ontario to Manitoba southward to Florida and Texas and widely distributed east of this area as a weed. It is a rough, hairy herb, about 2 ft. high, with thick, lance-shaped, slightly toothed leaves and long leafless flower stalks each bearing a single large head, 3 in. to 4 in. across, composed of 10–20 brilliant golden-yellow ray flowers surrounding a dark brown cone-shaped centre (disk). This plant, which is one of the most handsome American wild flowers, is grown for ornament and is the State flower of Maryland. (See **GOLDEN-GLOW**; **RUDBECKIA**)

BLACKFISH, the name applied to various dark-coloured fishes. In England, it is *Centrolophus niger*, a scombroid fish about 2 ft. long and shaped like a perch. In the United States, it most commonly refers to the tautog (*q v.*), but is also used of a sea bass (*Centropristis striatus*) of Atlantic waters, and a minnow (*Orthodon microlepidotus*) of central California. In Alaska, the blackfish is the small, fresh-water *Dallia pectoralis*. By whalers the word is used to denote Cetacea (*q v.*) of the genus *Globicephalus*, which includes the ca'ing or pilot whale (*G. melas*).

BLACKFOOT, a group of three closely related and allied Algonkin tribes in Alberta and Montana, also known as Siksika and comprising the Blackfoot proper, Piegan and Blood. During the 19th century the Athabascan Sarsi and the Atsina, a branch of

BLACKFOOT INDIAN RELIGIOUS CEREMONY IN GLACIER NATIONAL PARK
The Indians, dressed in native costume, are offering prayer to the God of the Underwater on the shore of Two Medicine Lake

the Algonkin Arapaho, were closely associated with them. Although situated near the north-western limit of the abundant range of the bison, the Blackfoot shared the culture of the Plains tribe in pure form. Their separation both from the central-eastern Algonkin and the Arapaho must be ancient, as shown by the specialization of their language. They originally numbered perhaps 3,000 per tribe, of whom 4,635 remained in 1909—2,440 on three reservations in Alberta, 2,195 on American soil.

See G. B. Grinnell, *Blackfoot Lodge Tales* (1892); J. W. Schultz, *My Life as an Indian* (1907); C. Wissler, *Am. Mus. Nat. Hist. Anthr. Pap.*, vols. v., vii. (1910–12).

BLACKFOOT, a city of Idaho, U.S.A., on the Snake river, Federal highway 91, and the Oregon Short Line of the Union Pacific railway system, about halfway between Pocatello and Idaho falls, at an elevation of 4,502 ft; the county seat of Bingham county. The population in 1920 was 3,937. It is the shipping, trading, and educational centre for a prosperous irrigated agricultural, grazing, and mining district, and has sugar-beet and cheese factories. The State insane asylum is located here. Just south of the city is the Fort Hall Indian reservation; ten miles west is the site of a Hudson Bay Company trading post, which was the first white settlement in Idaho and one of the first west of the Rockies. About 60 m N.W. is the Craters of the Moon national monument, which contains remarkable lava tunnels and caves, with fantastic formations coloured in reds and blues, and many other volcanic phenomena resulting from comparatively recent eruptions.

BLACK FOREST, a mountain range of south-west Germany, mainly in the republic of Baden, with about a third in Württemberg (Ger. *Schwarzwald*). Area about 1,800 sq.m.; total length, about 100 m.; breadth varying from 10–15 m. Structurally and topographically the Black Forest forms the counterpart of the Vosges, which stand across the sunken Alsace valley drained by the Rhine. The stepped opposing flanks of both ranges are minor results of the cataclysm caused probably by the Jura and Alpine folds, which shattered this old resistant block. The hills are mainly conical in shape and composed of gneiss, granite (in the south), and red sandstone. To the north-east they slope to the valleys of Neckar and Nagold. The range is cut off sharply by the Rhine on the south. It is divided into two parts by the deep Kinzig valley, with the highest summits, *e.g.*, Feldberg (4,900 ft), Herzogenhorn (4,600), and Blossling (4,260), to the south. The northern half has an average height of 2,000 ft. The climate in the higher districts is raw and only hardy cereals are grown; but the valleys are warm, with good pasture land and vineyards. Oak and beech woods clothe the lower spurs, while stretching up to 4,000 ft. are the extensive forests of fir which have made the terms "forest" and "mountain" synonyms here. The excellent timber is partly sawn in the valleys and partly exported down the Rhine in logs. The manufactures of watches, clocks, toys and musical instruments are typical of this and other forested areas of Central Europe. There are numerous mineral springs and watering places, *e.g.*, Baden-Baden and Wildbad. The towns of Freiburg, Rastatt, Offenburg and Lahr lie under the western slopes. The Black Forest is a favourite tourist resort and is reached by numerous railways.

BLACK FRIDAY, a term applied to several Fridays upon which serious upheavals or crises occurred. The outstanding financial Black Fridays are: (1) May 11, 1866, when the banking house of Overend and Gurney, of London, failed, resulting in widespread business and financial distress. (2) Sept. 24, 1869, the American Black Friday. For some time the balance of trade had been setting steadily against the United States and gold was being drained out of the country in tremendous amounts. So acute had conditions become that the U.S. Treasury had even discontinued the sale of gold. Many had gone "short" on gold and this suggested to Jay Gould and his associate, James Fisk, an opportunity to corner the available gold supply, engineer a "bull market" and compel the "shorts" to cover at high prices. In less than a month the price of gold was pushed up from 133 to 162½, which culminating price was reached on Black Friday and brought about a crisis in the securities market. The Government was largely responsible for breaking the corner by the purchase of \$4,000,000 of its bonds with gold.

BLACK HAW (*Viburnum prunifolium*), a North American shrub or small tree of the honeysuckle family (Caprifoliaceae), called also stag-bush and sheep-berry. It grows in dry soil from Connecticut and southern New York westward to Michigan and southward to northern Georgia and eastern Kansas. Although somewhat bushy in habit, with a short, usually crooked trunk, 6 in. to 8 in. in diameter, and rigid, spreading branches, it sometimes reaches 30 ft in height. It bears smooth, ovate very finely toothed leaves and numerous small white flowers in compact clusters, 2 in. to 4 in. broad, and sweet, edible, bluish-black fruits

(drupes), about $\frac{1}{2}$ in. long, each containing a much flattened stone. The similar but larger southern black haw (*V. rufidulum*), sometimes 40 ft. high, with fruit $\frac{1}{2}$ in. or more long and containing a nearly orbicular stone, is found in dry upland woods from Virginia westward to Missouri and southward to Florida and Texas. The nanny-berry (*V. Lentago*) is in some districts called also black haw. (See VIBURNUM.)

BLACK HAWK [*Ma 'kata-wimesheka 'ka*, "Black Sparrow Hawk"] (1767-1838), American Indian warrior, was born at the Sauk village on Rock river, near the Mississippi, in 1767. This beautiful territory was long coveted by the whites, and he and his people, who were so much under British influence as to be called the British band, were subjected to various acts of abuse by encroaching white squatters. As early as 1804 a few chiefs agreed to remove to the west of the Mississippi in return for an annuity of \$1,000, a manifestly unfair agreement obtained by very questionable methods, but which was reaffirmed by the Indians in later treaties. In 1831 Black Hawk's threat of force to evict the usurpers caused the Illinois volunteers to march to the latter's rescue and the Indians to withdraw to the west bank of the Mississippi, whence they agreed not to return without the Government's permission. Famine conditions prevailed among the red men who had left their growing crops in the Illinois country; and the next spring with women, children and tribal possessions Black Hawk recrossed the river to plant a new crop. Instant panic prevailed among the settlers, and the undisciplined militia shot down one of the Indians carrying a flag of truce. Black Hawk, enraged, began to harry the border, for a time being successful. He was defeated, however, at Wisconsin Heights by volunteers under Colonel Henry Dodge and James D. Henry, and fleeing westward, his band, which was by this time in a starving condition, was practically destroyed at the battle, or rather massacre, of the Bad Axe river. The cold-blooded way in which old men, little children and women were all destroyed and a plea for mercy and a flag of truce alike disregarded make the whole affair one of the darkest blots in the shameful record of the whites' spoliation of the Indian. Black Hawk himself was captured, confined for a short time in Fortress Monroe, Va., and then taken by the Government through the principal eastern cities. On his release he settled on the Sauk and Fox reservation on the Des Moines river, in Iowa, where he died on Oct. 3, 1838. A statue of him by Lorado Taft has been erected on a high bluff overlooking the Rock river near Oregon, Illinois. Black Hawk was of a romantic and ambitious temper, and though he lacked the vision and the statesmanship of Pontiac or Tecumseh, there can be no doubt of the sincerity of his feeling for his territory and his people and of the shamefulness of the treatment accorded to him and his followers by the whites.

Black Hawk's own story was told in *Life of Ma-ka-tai-me-she-kiak* (1834); Benjamin Drake's *Life of Black Hawk* (1846) was a popular early biography. An example of the numerous contemporary accounts is A. Wakefield's *History of the Black Hawk War* (1834), which was edited by F. E. Stevens in 1908. See also F. E. Stevens, *The Black Hawk War* (1903); numerous articles in the Wisconsin Historical Society Collections; the essay in R. G. Thwaites, *How*

George Rogers Clark Won the Northwest (1903); J. F. Snyder, "The Burial and Resurrection of Black Hawk," *Ill. State Hist. Soc. Jour.*, vol. iv., p. 47-56 (Springfield, Ill., 1911); and Amer. Mills Stocking, *The Sauk Indians and Their Great Chiefs Black Hawk and Keokuk* (Rock Island, Ill., 1926).

BLACKHEATH, an open common in the south-east of London, England, mainly in the metropolitan borough of Lewisham. This high-lying tract was crossed by the Roman Watling Street from Kent, on a line approximating to that of the modern Shooter's Hill; and was a rallying ground of Wat Tyler (1381), of Jack Cade (1450), and of Audley, leader of the Cornish rebels, defeated and captured here in 1497. The citizens of London greeted Henry V. here on his return from Agincourt, and here the army of the Restoration met Charles II. The introduction into England of the game of golf is traditionally placed here in 1608, and attributed to King James I. and his Scottish followers. The common, the area of which is 267 acres, is used as a pleasure resort. For the residential district to which Blackheath gives name, see LEWISHAM.

BLACK HILLS, an isolated group of mountains in the U.S.A. covering an area of about 6,000 sq.m. in the adjoining corners of South Dakota and Wyoming. They rise on an average some 2,000 ft. above their base, the highest peak, Harney, having an altitude above the sea of 7,216 ft. They are drained and in large part enclosed by the North (or Belle Fourche) and South forks of the Cheyenne river, and are surrounded by semi-arid, alkaline plains lying 3,000 to 3,500 ft. above the sea. The mass has an elliptical shape, its long axis, which extends nearly north-north-west to south-south-east, being about 120 m. and its shorter axis about 40 m. long. The hills are formed by a short, broad fold, which is flat or nearly so on its summit. From this fold the stratified beds have in large part been removed, the more recent having been almost entirely eroded from the elevated mass. The edges of these are now found encircling the mountains and forming a series of fairly continuous rims. The carboniferous and older stratified beds still cover the west half of the hills, while from the east half they have been removed, exposing the granite. Scientific exploration began in 1849, and systematic geological investigation about 1875. Rich gold placers had already been discovered, and in 1875 the Sioux Indians, within whose territory the hills had until then been included, were removed, and the lands were open to white settlers. Subsequently low-grade quartz mines were found and developed. These have furnished a notable part of the gold supply of the country (about \$100,000,000 from 1875 to 1901). There are still one or two gold mines working low-grade ore. The silver product from 1879 to 1901 was about \$4,154,000. Deposits of copper, tin, iron and tungsten have been discovered, and a variety of other mineral products (graphite, mica, spodumene, coal, petroleum, etc.). In sharp contrast to the surrounding plains the climate is sub-humid, especially in the higher Harney region. There is an abundance of fertile soil and magnificent grazing land. A third of the total area is covered with forests of pine and other trees, which have for the most part been made a forest-reserve by the national government.

BIBLIOGRAPHY.—See the publications of the U.S.A. geological survey (especially Professional Paper No. 26, *Economic Resources of the Northern Black Hills*, 1904), and of the South Dakota School of Mines (Bulletin No. 4, containing a history and bibliography of Black Hills investigations); also R. L. Dodge, *The Black Hills: A Minute description* . . . (1876).

BLACK HILLS HIGHWAY, a thoroughfare connecting Chicago, Ill., with Denver, Colorado. It is about 1,300 m. long. The roadway is paved and improved through Illinois, Wisconsin,

Iowa and again in Colorado. It passes over the famous Rosebud bridge spanning the Missouri river and through the Black Hills of South Dakota. For 3000 ft. it affords unusual views of the Rocky mountains. Milwaukee, Madison, Mason City, Lusk and Cheyenne are some of the cities through which it passes.

BLACKIE, JOHN STUART (1800–1805), Scottish scholar and man of letters, was born in Glasgow, July 28 1800. After studying theology at Aberdeen, he spent some years in Germany and Italy, and on his return became a member of the Faculty of Advocates (1834). In 1834 he published a translation of *Faust*, and in May 1839 he was appointed professor of Latin at the Marischal college, Aberdeen. After the appearance of his translation of Aeschylus (1850) he was appointed to the professorship of Greek at Edinburgh (1852), a post which he held for 30 years. He died on March 2 1805. Scottish as well as classical subjects aroused his enthusiasm, as his works show, and he was one of the "characters" of Edinburgh of his day.

See Anna M. Stoddart, biography, *John Stuart Blackie* (1895); A. Stodart-Walker, *Selected Poems of J. S. Blackie*, with an appreciation (1896); Howard Angus Kennedy, *Professor Blackie* (1805); *Letters of John Stuart Blackie* (1909), and *Notes of a Life* (1910) both edited by A. Stodart-Walker.

BLACKING. The manufacture of blacking, a compound used in the polishing of old-fashioned coarse leathers, is a very ancient one, and was at one time a large and flourishing industry. Blacking is composed of charcoal black, lamp-black, sugar, oil, and fat in varying proportions, and is prepared either as a paste packed in tins or as a liquid put up in bottles. The blacking is spread upon the leather and then polished to give a brilliant "shine," as the boot-black calls it. The "cleaning" of leather boots by this process thus amounts to the application to footwear of an exceedingly dirty substance. While boots were made of the old-fashioned coarse leathers, blacking was largely called for, but the modern introduction of willow-calf and other fancy leathers and the general substitution of light for heavy footwear have made it unnecessary to use blacking. Willow-calf, whether finished black or brown or any other colour, can with ease and comparative cleanliness be polished with a preparation of wax and turpentine, and many forms of such "boot-polish" are made and sold.

The turnover from blacking to boot-polish, although a small detail of trade, is significant of the general change of fashion from the heavy to the light, from the shapeless to the graceful, from the dull to the bright, which has characterized the beginning of the twentieth century.

BLACK ISLE, THE, a district in the east of the county of Ross and Cromarty, Scotland, bounded north by Cromarty Firth, east by Moray Firth, south by Inner Moray Firth (or Firth of Inverness) and Beaully Firth, and west by the river Conon and the parish of Urray. (See ROSS AND CROMARTY.)

BLACK JACK, a bludgeon-like weapon consisting of a lead slug attached to a leather thong. The more carefully contrived black jacks contain a spring within the handle which serves to ease the effect of the impact upon the wrist of the one who wields the weapon. The black jack has the reputation of being a characteristic weapon of urban gangsters and rowdies. In England a black jack or black-jack was a big leather quart pot or drinking cup, often with a silver rim; see the conclusion of the song, "Simon the Cellarer".

"But yo, ho, ho! His nose doth show
How oft the Black Jack to his lips doth go."

BLACKLEAD, a name for graphite (*qv*) or plumbago. Preparations of graphite are commonly sold as "blacklead," and were at one time largely used for the cleaning and brightening of iron firegrates and iron fenders. Many homes were at one time, and some still are, fitted with iron stoves made upon the supposition that their users would regularly coat them with blacklead. This dirty and unnecessary work has been rendered obsolete by the introduction of better-finished appliances. In moulding with wax, blacklead is used as a coating for the mould in order to keep it from sticking.

BLACKLEG, a slang term in use since the 18th century for a cheat or turf swindler. Its modern use is as a term of reproach for a worker who refuses to come out on strike with his fellows,

or, sometimes, but less correctly, for those who decline to join their appropriate trade society or union. Similarly, to "blackleg" is to return to work before the union or the general body of strikers have agreed to do so; or to take the place of workers who are on strike or have been locked out.

Like the equally opprobrious word "scab," "blackleg" originally means a disease of cattle or sheep.

BLACK LETTER, the name of the type copied from the fifteenth-century style of handwriting used in Germany, Holland and England. It was first employed by Caxton before 1480, and

was later used in all his books. Black letter, also called Gothic, did not give way to the Roman type revived in the Italian Renaissance until the 16th century. In the accompanying drawings are shown (1) a reproduction of Caxton's type and (2) a specimen of modern "Old English" used for decorative purposes. Black letter is still commonly used in Germany in books and newspapers. (See TYPOGRAPHY.)

BLACK LIST. A general term used to describe a list of persons considered obnoxious for reasons good or bad. In the World War, the blockade of Germany by the allies was rendered very difficult by the free trading of neutral traders, especially those of Scandinavia, Holland and Switzerland, with the Central European powers (see BLOCKADE). This led to the drawing up by the British Government of a list of Continental and other firms and persons, acting as suppliers to the enemy, with whom British subjects were forbidden to trade under the Trading with the Enemy act. This was called the black list. The term has also been used to describe a list of defaulters and unreliable persons circulated to traders by trade protection institutions.

BLACKLOCK, THOMAS (1721–1791), Scottish poet the son of a bricklayer, was born at Annan, Dumfriesshire, on Nov. 10, 1721, and died at Edinburgh on July 7, 1791. When not quite six months old he lost his sight by smallpox, and his career is largely interesting as that of one who achieved what he did in spite of blindness. About 1740, some of Blacklock's poems began to be handed about among his acquaintances and friends, who arranged for his education at the grammar-school, and subsequently at the University of Edinburgh, where he was a student of divinity. His first volume of *Poems* was published in 1746. In 1754 he became deputy librarian for the Faculty of Advocates, by the kindness of Hume. He was eventually estranged from Hume, and defended James Beattie's attack on that philosopher. Blacklock was among the first friends of Burns in Edinburgh, being one of the earliest to recognize his genius. In 1762 he was ordained minister of the church of Kirkcudbright, a position which he soon resigned.

An edition of his poems in 1793 contains a life by Henry Mackenzie.

BLACK MAGIC: see CONJURING

BLACKMAIL, in English law, a term used with three special meanings at different times. (1) The primary meaning of "black-

mail" was rent paid in labour, grain or baser metal, *i.e.*, money other than sterling money, called *reditus nigri* in contradistinction to rent paid in silver or white money (*mailles blanches*). (2) In Scotland and the northern counties of England it signified a tribute in money, corn, cattle or other consideration exacted from farmers and small owners by freebooters in return for immunity. By a statute of 1601 it was made a felony without benefit of clergy to receive or pay such tribute, but the practice lingered until the union of England and Scotland in 1707. (3) The word now signifies extortion or attempted extortion of money or property by threats, and the criminal offence is now dealt with by ss. 29, 30 and 31 of the Larceny Act, 1916. Under s. 29 every person who utters, knowing the contents thereof, any letter or writing demanding of any person with menaces, and without any reasonable or probable cause, any property or valuable thing, or accusing or threatening to accuse any other person of any serious or infamous crime with intent to extort or gain any property or valuable thing, or accuses or threatens to accuse with like intent another person of a like crime is guilty of a felony and liable to penal servitude for life. It has been held by the Court of Criminal Appeal in *Rex v. Dymond*, 26 Cox C.C. 621, that it is no defence to a charge of this description that the person honestly believes that he has reasonable or probable cause for demanding the money, but that the offence is constituted if it is proved that the accused uttered the writing, demanded property or a valuable thing with menaces, knew the contents of the writing, and had no reasonable or probable cause for making the demand. Again, it was held in *Rex v. Denyer*, 28 Cox C.C. 153, that where a letter was uttered demanding money with threats it was immaterial that the motive in writing the letter was the protection of trade interests. By the same section a similar penalty may be inflicted where a person, with intent to defraud or injure, by unlawful violence or by accusing or threatening to accuse a person of a like crime, compels or induces the execution, alteration or destruction of valuable securities. Section 30 deals with demanding with menaces with intent to steal, where the maximum period of penal servitude is five years, and s. 31 with threatening to publish or proposing to abstain from publishing libellous or other matter with intent to extort. This last is declared to be only a misdemeanour and the maximum imprisonment is for a term not exceeding two years (W. DE B. H.)

In America.—In American law blackmail, or extortion, which is frequently treated as a synonymous term, is, obtaining or endeavouring to obtain money or property or to procure any wrongful act by threats or intimidation. The threat may be to accuse of a crime, do an injury, publish a libel or to bring disgrace and shame upon the person threatened. It may be a threat to injure a third party as well as to injure the person from whom the money is demanded. In some jurisdictions a distinction is made between intimidation under colour of official right and other threats or intimidation. The term extortion is confined to the former and blackmail to the latter. In other jurisdictions, blackmail by written threat is made a more serious offence than by oral threats, the latter being classed as a misdemeanor, the former as a felony. It is not blackmail to demand in good faith indemnity for a wrong actually suffered even though legal proceedings to enforce the demand might in fact bring shame and disgrace upon the person addressed. (B. RE.)

BLACKMORE, SIR RICHARD (c. 1650–1729), English physician and writer, was born at Corsham, in Wiltshire, and educated at Westminster school and St. Edmund hall, Oxford. After graduating in medicine at Padua, he settled in practice as a physician in London, and held the office of physician in ordinary both to William III. and Anne. Blackmore was a prolific writer of verse. His *Prince Arthur, an Heroick Poem in X Books* appeared in 1695, and was followed by six other long poems before 1723. Of these *Creation . . .* (1712), a philosophic poem intended to unfold the intellectual philosophy of Locke, was the most favourably received.

BLACKMORE, RICHARD DODDRIDGE (1825–1900), English novelist, was born at Longworth, Berks, of which village his father was curate-in-charge. He was educated at

Blundell's school, Tiverton, and Exeter college, Oxford, and was called to the bar at the Middle Temple in 1852. His first publication was a volume of *Poems by Melanther* (1854), which showed no particular promise, nor did the succeeding volume, *Epullia* (1855), suggest that Blackmore had the makings of a poet. In 1864 he published his first novel, *Clara Vaughan*, the merits of which were promptly recognized. *Cradock Nowell* (1866) followed, but it was in 1869 that he suddenly sprang into fame with *Lorna Doone*. This fine story was a pioneer in the romantic revival; and, appearing at a jaded hour, it was presently recognized as a work of singular charm, vigour and imagination. Though Blackmore wrote many other capital stories, he is remembered almost exclusively as the author of *Lorna Doone*, now an accepted classic of the West country.

BLACK MOUNTAIN, mountain range and district on the Hazara border of the North-West Frontier Province of India, in 34° 30' N., 73° E. Length, 25 to 50m; average height, 8,000ft. It rises from the Indus basin near the village of Kiara, and runs north parallel to the river. The tribes which inhabit the west of the Black Mountain are all sub-sections of the Yusafzai Pathans. The Black Mountain is chiefly notable for four British expeditions:

1. Under Lt.-Col. F. Mackeson, in 1852–54, against the Hassanzais. The occasion was the murder of two British customs officers. A force of 3,800 British troops traversed their country, destroying their villages and grain, etc.

2. Under Maj.-Gen. A. T. Wilde in 1868. The occasion was an attack on a British police post at Oghi in the Agror Valley by all three tribes. A force of 12,500 British troops entered the country and the tribes made submission.

3. The first Hazara expedition in 1888. The cause was the constant raids made by the tribes on villages in British territory, culminating in an attack on a small British detachment, in which two English officers were killed. A force of 12,500 British troops traversed the country of the tribes, and severely punished them. Punishment was also inflicted on the Hindustani Fanatics of Palosi.

4. The second Hazara expedition of 1891. The Black Mountain tribes fired on a force within British limits. A force of 7,300 British troops traversed the country. The tribesmen made their submission and entered into an agreement with the Government to preserve the peace of the border.

The Black Mountain tribes took no part in the general frontier rising of 1897, and after the disappearance of the Hindustani Fanatics they sank into comparative unimportance.

BLACK PLATE: see TINPLATE.

BLACKPOOL, municipal, county and parliamentary borough, Lancashire, England. Pop. (1921) municipal borough, 99,640; Parliamentary borough, 125,516. It is 46m. N. of Liverpool and is served by the L.M.S. railway. The town is almost entirely of 19th and 20th century growth, its rapid development being related to that of the Lancashire industrial area. With the development of a fast railway service, together with many places of public amusement, Blackpool attracted visitors from all over the country. The sea-front with its sandy beach is well laid out, an important extension of the promenade having been made in 1912, and since that date the town has extended a great deal northwards. In 1922, 274 acres of undeveloped land behind the town were bought for a park, and laid out on modern lines.

The borough was created in 1876 (county borough 1904) and is governed by a council of 25 members.

BLACK RIVER, a river of the United States, flowing into the Chesapeake Bay. It is 125 miles long and has a drainage area of 1,200 square miles.

BLACK RIVER CANAL SYSTEM, a canal system in the United States, connecting the Black River with the Mississippi River.

BLACK ROCK DESERT, a desert in Pershing counties, Nevada. It is 20m. wide, and extends from the north to the south. The belt of greatest aridity extends from the north to the south. Pine Forest and Black Rock are the "sink" of the Quinn.

with water only a few inches deep. When the water evaporates in the summer it leaves a clay-bed of remarkable hardness, which is frequently encrusted with saline matter of a snowy whiteness. This barren plain is practically devoid of vegetation, and from its surface alkaline dust is blown into vast clouds by the summer winds.

BLACK ROD (more fully, "Gentleman Usher of the Black Rod"), an official of the House of Lords, instituted in 1350. His appointment is by royal letters patent, and his title is due to his staff of office, an ebony stick surmounted with a gold lion. He is a personal attendant of the sovereign in the Upper House, and is also usher of the order of the Garter, being doorkeeper at the meetings of the knights' chapter. He is responsible for the maintenance of order in the House of Lords, and on him falls the duty of arresting any peer guilty of breach of privilege or other offence of which the House takes cognizance. In this respect his duties correspond to those of serjeant-at-arms in the Commons. But the duty which brings him most into prominence is that of summoning the Commons and their speaker to the Upper House to hear a speech from the throne (*see ADDRESS*), or the royal assent given to bills. Black Rod is on such occasions the central figure of a curious ceremony of much historic significance. As soon as the attendants of the House of Commons are aware of his approach, they close the doors in his face. Black Rod then strikes three times with his staff, and on being asked "Who is there?" replies "Black Rod." Being then admitted he advances to the bar of the House, makes three obeisances and says, "Mr. Speaker, the King commands this honourable House to attend His Majesty immediately in the House of Lords." This formality originated in the famous attempt of Charles I. to arrest the five members, Hampden, Pym, Holles, Haselrige and Strode, in 1642. The House of Commons has ever since maintained its right of freedom of speech and uninterrupted debate by the closing of the doors on the king's representative.

BLACK SEA, a body of water between lat. 41° and 45° N., but extending to about 47° near Odessa, bounded north by south Russia; west by Rumania, Bulgaria and Turkey; and south and east by Asia Minor. It is also called Euxine (anc., *Pontus Euxinus*); the early Greek navigators named it *axeinos* ("hostile to

greatest depth is 1,160 fathoms near the centre, there being only one basin. Large powerful rivers flow into the Black sea, the Danube, Dniester, Dnieper, Don, etc. The Black sea shows conditions different from those of the Mediterranean or any other sea. The existence of sulphuretted hydrogen in great quantities below 80 fathoms (4cu.cm. per litre and more in the depths below 350 fathoms), the extensive chemical precipitation of calcium carbonate, the stagnant nature of its deep waters and the absence of deep sea-life are highly peculiar features. Higher organic life is not known to exist below 80 fathoms. Fossil *Dreissena*, *Cardium* and other molluscs have, however, been dredged up, which help to show that the Black sea was formerly much like the Caspian to-day. According to N. Andrusov, when in an earlier geological period the union of Black sea and Mediterranean through the Bosphorus took place, salt water rushed into it along the bottom of the Bosphorus and killed the fauna of the less saline waters. This produced sulphuretted hydrogen (H₂S) which is found in the deposits, as well as in the deeper waters.

Another explanation of the existence of this sulphuretted hydrogen in the waters of the Black sea is based upon present conditions. This sea receives far more fresh water from rain and rivers than it loses by evaporation; the salt-content of the surface water in summer and in winter is therefore only 15 to 18‰ (against 37 to 39‰ in the Mediterranean); below 50 fathoms the water is more salt (20 to 22.5‰), and this salt water is largely brought by the undercurrent through the Dardanelles and Bosphorus. This saltier water occupies the depths of the Black sea. Apart from two winter months the surface water is much warmer than the deep water and both temperature and relative freshness make the surface water comparatively light; this holds good even in winter. This covering impermeable layer lies, therefore, like a coating of oil over the deep water of the Black sea and hinders gaseous exchange with the atmosphere; the water below 50 fathoms receives no oxygen and the living organisms of the surface waters sinking after death into the depths, their remains cannot be oxidized but decay into carbonic acid and sulphuretted hydrogen. However this may be, there is an immense depth of water in the Black sea (800 to 1,160 fathoms) without any organic life, a unique feature for the world's seas. This explanation is also supported by the fact that the coldest water (44.5°) is not on the sea floor as in the open ocean, but round about a depth of 50 fathoms. The cold winter water cannot sink below this, and this is the downward limit of life; the water below is poisoned.

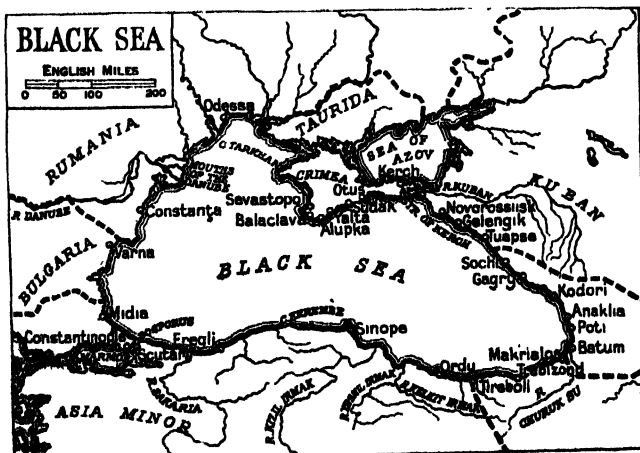

There is a counter-clockwise surface current in the Black sea and the surplus fresh water flows off from the Bosphorus. Tides are hardly distinguishable. The climate is very harsh save in the summer months; strong cold north, north-east and north-west winds are dominant, especially in winter, when they give rise to frequent severe storms. Only the south coast of the Crimea resembles in any way the Mediterranean in climate. Clouds are common in spring. At Odessa there is ice on the sea for an average of 16 to 20 days in winter, in the Strait of Kertch for 41 days.

Black sea was formerly the name of a military district of the Kuban, Russia, now included in the N. Caucasian area (*qv*).

HISTORY

The Black Sea, the "Pontus Euxinus" of the Romans, has played an important part in the economic and political history of Eastern Europe from earliest times. Across it sailed Jason to Colchis, the modern Georgia, in search of the Golden Fleece; and many legends of antiquity are doubtless idealized versions of early commercial or political ventures. With the establishment of Constantinople as capital of the later Roman empire, the political and strategic importance of the Black sea was greatly increased. Merchandise from Persia and its adjacent lands was shipped from Trebizond to Constantinople, for distribution through Western Europe. Another great trade route led from the Baltic to the

MAP OF THE BLACK SEA, SHOWING EUROPEAN AND ASIATIC BOUNDARIES
The Black Sea is an important outlet for the wheat harvest of Southern Russia and Bessarabia and, through Batumi and Poti, for the produce of the Caucasus. It has an area of about 164,000 sq. miles, and is connected with the Mediterranean through the Bosphorus, Sea of Marmora, and Dardanelles. Its distinguishing feature is the absence of organic sea life below a

depth of 50 fathoms. The growth of Greek colonies on its shores, especially in the north, was "friendly to strangers". The northern coast is fringed by a strait of the same name connecting it with the Sea of Azov, and at its south-west end it opens into the Sea of Marmora and the Dardanelles. Its area of about 164,000 sq. m. is less than that of the Baltic; its average depth is 650 fathoms. The

mail" was rent paid in labour, grain or baser metal, *i.e.*, money other than sterling money, called *reditus nigri* in contradistinction to rent paid in silver or white money (*maillles blanches*). (2) In Scotland and the northern counties of England it signified a tribute in money, corn, cattle or other consideration exacted from farmers and small owners by freebooters in return for immunity. By a statute of 1601 it was made a felony without benefit of clergy to receive or pay such tribute, but the practice lingered until the union of England and Scotland in 1707. (3) The word now signifies extortion or attempted extortion of money or property by threats, and the criminal offence is now dealt with by ss. 29, 30 and 31 of the Larceny Act, 1916. Under s. 29 every person who utters, knowing the contents thereof, any letter or writing demanding of any person with menaces, and without any reasonable or probable cause, any property or valuable thing, or accusing or threatening to accuse any other person of any serious or infamous crime with intent to extort or gain any property or valuable thing, or accuses or threatens to accuse with like intent another person of a like crime is guilty of a felony and liable to penal servitude for life. It has been held by the Court of Criminal Appeal in *Rex v. Dymond*, 26 Cox C.C. 621, that it is no defence to a charge of this description that the person honestly believes that he has reasonable or probable cause for demanding the money, but that the offence is constituted if it is proved that the accused uttered the writing, demanded property or a valuable thing with menaces, knew the contents of the writing, and had no reasonable or probable cause for making the demand. Again, it was held in *Rex v. Denyer*, 28 Cox C.C. 153, that where a letter was uttered demanding money with threats it was immaterial that the motive in writing the letter was the protection of trade interests. By the same section a similar penalty may be inflicted where a person, with intent to defraud or injure, by unlawful violence or by accusing or threatening to accuse a person of a like crime, compels or induces the execution, alteration or destruction of valuable securities. Section 30 deals with demanding with menaces with intent to steal, where the maximum period of penal servitude is five years, and s. 31 with threatening to publish or proposing to abstain from publishing libellous or other matter with intent to extort. This last is declared to be only a misdemeanour and the maximum imprisonment is for a term not exceeding two years. (W. DE B. H.)

In America.—In American law blackmail, or extortion, which is frequently treated as a synonymous term, is, obtaining or endeavouring to obtain money or property or to procure any wrongful act by threats or intimidation. The threat may be to accuse of a crime, do an injury, publish a libel or to bring disgrace and shame upon the person threatened. It may be a threat to injure a third party as well as to injure the person from whom the money is demanded. In some jurisdictions a distinction is made between intimidation under colour of official right and other threats or intimidation. The term extortion is confined to the former and blackmail to the latter. In other jurisdictions, blackmail by written threat is made a more serious offence than by oral threats, the latter being classed as a misdemeanour, the former as a felony. It is not blackmail to demand in good faith indemnity for a wrong actually suffered even though legal proceedings to enforce the demand might in fact bring shame and disgrace upon the person addressed. (B. RE.)

BLACKMORE, SIR RICHARD (c. 1650–1720), English physician and writer, was born at Corsham, in Wiltshire, and educated at Westminster school and St. Edmund hall, Oxford. After graduating in medicine at Padua, he settled in practice as a physician in London, and held the office of physician in ordinary both to William III. and Anne. Blackmore was a prolific writer of verse. His *Prince Arthur, an Heroick Poem in X Books* appeared in 1605, and was followed by six other long poems before 1723. Of these *Creation . . .* (1712), a philosophic poem intended to unfold the intellectual philosophy of Locke, was the most favourably received.

BLACKMORE, RICHARD DODDRIDGE (1825–1900), English novelist, was born at Longworth, Berks, of which village his father was curate-in-charge. He was educated at

Blundell's school, Tiverton, and Exeter college, Oxford, and was called to the bar at the Middle Temple in 1852. His first publication was a volume of *Poems by Melanther* (1854), which showed no particular promise, nor did the succeeding volume, *Epullia* (1855), suggest that Blackmore had the makings of a poet. In 1864 he published his first novel, *Clara Vaughan*, the merits of which were promptly recognized. *Cradock Nowell* (1866) followed, but it was in 1869 that he suddenly sprang into fame with *Lorna Doone*. This fine story was a pioneer in the romantic revival; and, appearing at a jaded hour, it was presently recognized as a work of singular charm, vigour and imagination. Though Blackmore wrote many other capital stories, he is remembered almost exclusively as the author of *Lorna Doone*, now an accepted classic of the West country.

BLACK MOUNTAIN, mountain range and district on the Hazara border of the North-West Frontier Province of India, in 34° 30' N., 73° E. Length, 25 to 50m.; average height, 8,000ft. It rises from the Indus basin near the village of Kiara, and runs north parallel to the river. The tribes which inhabit the west of the Black Mountain are all sub-sections of the Yusafzai Pathans. The Black Mountain is chiefly notable for four British expeditions:

1. Under Lt-Col. F. Mackeson, in 1852–54, against the Hassanzais. The occasion was the murder of two British customs officers. A force of 3,800 British troops traversed their country, destroying their villages and grain, etc.

2. Under Maj.-Gen. A. T. Wilde in 1868. The occasion was an attack on a British police post at Oghi in the Agror Valley by all three tribes. A force of 12,500 British troops entered the country and the tribes made submission.

3. The first Hazara expedition in 1888. The cause was the constant raids made by the tribes on villages in British territory, culminating in an attack on a small British detachment, in which two English officers were killed. A force of 12,500 British troops traversed the country of the tribes, and severely punished them. Punishment was also inflicted on the Hindustani Fanatics of Palosi.

4. The second Hazara expedition of 1891. The Black Mountain tribes fired on a force within British limits. A force of 7,300 British troops traversed the country. The tribesmen made their submission and entered into an agreement with the Government to preserve the peace of the border.

The Black Mountain tribes took no part in the general frontier rising of 1897, and after the disappearance of the Hindustani Fanatics they sank into comparative unimportance.

BLACK PLATE: see TINPLATE.

BLACKPOOL, municipal, county and parliamentary borough, Lancashire, England. Pop. (1921) municipal borough, 99,640; Parliamentary borough, 125,516. It is 46m N. of Liverpool and is served by the L.M.S. railway. The town is almost entirely of 19th and 20th century growth, its rapid development being related to that of the Lancashire industrial area. With the development of a fast railway service, together with many places of public amusement, Blackpool attracted visitors from all over the country. The sea-front with its sandy beach is well laid out, an important extension of the promenade having been made in 1912, and since that date the town has extended a great deal northwards. In 1922, 274 acres of undeveloped land behind the town were bought for a park, and laid out on modern lines.

The borough was created in 1876 (county borough 1904) and is governed by a mayor, 12 aldermen and 36 councillors. It was made a parliamentary borough in 1918 with the incorporation of outlying districts (urban). It returns one member to Parliament. Area of county borough, 5,189 acres; of Parliamentary borough, 10,995 acres.

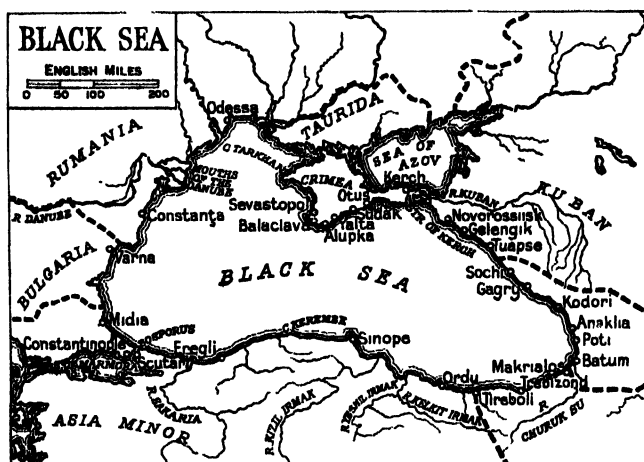

BLACK RIVER CANAL: see NEW YORK STATE BARGE CANAL SYSTEM.

BLACK ROCK DESERT, an arid region in Humboldt and Pershing counties, Nevada, U.S.A., about 70m. long and in some places 20m. wide, embracing an area of about 1,000 sq. miles. The belt of greatest aridity (less than 4in. of rainfall annually) extends from the north-east to the south-west just east of the Pine Forest and Black Rock mountain ranges. The desert serves as the "sink" of the Quinn river, and, at times, is largely covered

with water only a few inches deep. When the water evaporates in the summer it leaves a clay-bed of remarkable hardness, which is frequently encrusted with saline matter of a snowy whiteness. This barren plain is practically devoid of vegetation, and from its surface alkaline dust is blown into vast clouds by the summer winds.

BLACK ROD (more fully, "Gentleman Usher of the Black Rod"), an official of the House of Lords, instituted in 1350. His appointment is by royal letters patent, and his title is due to his staff of office, an ebony stick surmounted with a gold lion. He is a personal attendant of the sovereign in the Upper House, and is also usher of the order of the Garter, being doorkeeper at the meetings of the knights' chapter. He is responsible for the maintenance of order in the House of Lords, and on him falls the duty of arresting any peer guilty of breach of privilege or other offence of which the House takes cognizance. In this respect his duties correspond to those of serjeant-at-arms in the Commons. But the duty which brings him most into prominence is that of summoning the Commons and their speaker to the Upper House to hear a speech from the throne (*see ADDRESS*), or the royal assent given to bills. Black Rod is on such occasions the central figure of a curious ceremony of much historic significance. As soon as the attendants of the House of Commons are aware of his approach, they close the doors in his face. Black Rod then strikes three times with his staff, and on being asked "Who is there?" replies "Black Rod." Being then admitted he advances to the bar of the House, makes three obeisances and says, "Mr. Speaker, the King commands this honourable House to attend His Majesty immediately in the House of Lords." This formality originated in the famous attempt of Charles I. to arrest the five members, Hampden, Pym, Holles, Haslrigge and Strode, in 1642. The House of Commons has ever since maintained its right of freedom of speech and uninterrupted debate by the closing of the doors on the king's representative.

BLACK SEA, a body of water between lat 41° and 45° N, but extending to about 47° near Odessa, bounded north by south Russia; west by Rumania, Bulgaria and Turkey; and south and east by Asia Minor. It is also called Euxine (anc., *Pontus Euxinus*); the early Greek navigators named it *axeinos* ("hostile to

MAP OF THE BLACK SEA. SHOWING EUROPEAN AND ASIATIC BOUNDARIES. The Black Sea is an important outlet for the wheat harvest of Southern Russia and Bessarabia and, through Batumi and Poti, for the produce of the Caspian oilfields. It has an area of about 164,000 sq. miles, and is connected with the Mediterranean through the Bosphorus, Sea of Marmora, and Dardanelles. A unique feature is the absence of organic sea life below a depth of 80 fathoms.

strangers"), but with the growth of Greek colonies on its shores, it became *Euxenos* ("friendly to strangers"). The northern boundary is broken at Kertch by a strait of the same name connecting it with the Sea of Azov, and at its south-west end it opens through the Bosphorus, the Sea of Marmora and the Dardanelles to the Mediterranean. Its area of about 164,000 sq. m. is approximately the same as that of the Baltic; its average depth is much greater than that of the Baltic, namely, 650 fathoms. The

greatest depth is 1,160 fathoms near the centre, there being only one basin. Large powerful rivers flow into the Black sea, the Danube, Dniester, Dnieper, Don, etc. The Black sea shows conditions different from those of the Mediterranean or any other sea. The existence of sulphuretted hydrogen in great quantities below 80 fathoms (4 cu. cm. per litre and more in the depths below 350 fathoms), the extensive chemical precipitation of calcium carbonate, the stagnant nature of its deep waters and the absence of deep sea-life are highly peculiar features. Higher organic life is not known to exist below 80 fathoms. Fossil *Dreissena*, *Cardium* and other molluscs have, however, been dredged up, which help to show that the Black sea was formerly much like the Caspian to-day. According to N. Andrusov, when in an earlier geological period the union of Black sea and Mediterranean through the Bosphorus took place, salt water rushed into it along the bottom of the Bosphorus and killed the fauna of the less saline waters. This produced sulphuretted hydrogen (H_2S) which is found in the deposits, as well as in the deeper waters.

Another explanation of the existence of this sulphuretted hydrogen in the waters of the Black sea is based upon present conditions. This sea receives far more fresh water from rain and rivers than it loses by evaporation; the salt-content of the surface water in summer and in winter is therefore only 15 to 18‰ (against 37 to 39‰ in the Mediterranean); below 50 fathoms the water is more salt (20 to 22.5‰), and this salt water is largely brought by the undercurrent through the Dardanelles and Bosphorus. This saltier water occupies the depths of the Black sea. Apart from two winter months the surface water is much warmer than the deep water and both temperature and relative freshness make the surface water comparatively light; this holds good even in winter. This covering impermeable layer lies, therefore, like a coating of oil over the deep water of the Black sea and hinders gaseous exchange with the atmosphere; the water below 50 fathoms receives no oxygen and the living organisms of the surface waters sinking after death into the depths, their remains cannot be oxidized but decay into carbonic acid and sulphuretted hydrogen. However this may be, there is an immense depth of water in the Black sea (800 to 1,160 fathoms) without any organic life, a unique feature for the world's seas. This explanation is also supported by the fact that the coldest water (44.5°) is not on the sea floor as in the open ocean, but round about a depth of 50 fathoms. The cold winter water cannot sink below this, and this is the downward limit of life; the water below is poisoned.

There is a counter-clockwise surface current in the Black sea and the surplus fresh water flows off from the Bosphorus. Tides are hardly distinguishable. The climate is very harsh save in the summer months; strong cold north, north-east and north-west winds are dominant, especially in winter, when they give rise to frequent severe storms. Only the south coast of the Crimea resembles in any way the Mediterranean in climate. Clouds are common in spring. At Odessa there is ice on the sea for an average of 16 to 20 days in winter, in the Strait of Kertch for 41 days.

Black sea was formerly the name of a military district of the Kuban, Russia, now included in the N. Caucasian area (*q.v.*)

HISTORY

The Black Sea, the "Pontus Euxinus" of the Romans, has played an important part in the economic and political history of Eastern Europe from earliest times. Across it sailed Jason to Colchis, the modern Georgia, in search of the Golden Fleece; and many legends of antiquity are doubtless idealized versions of early commercial or political ventures. With the establishment of Constantinople as capital of the later Roman empire, the political and strategic importance of the Black sea was greatly increased. Merchandise from Persia and its adjacent lands was shipped from Trebizond to Constantinople, for distribution through Western Europe. Another great trade route led from the Baltic to the

Crimea, and hence to Constantinople. The name Euxinos, "hospitable to strangers," was probably a propitiatory euphemism for the older Axenos, "inhospitable."

With the capture of Constantinople by the Ottoman Turks in 1453, the trade of the Black sea suffered a set-back; soon, however, Italian, French, and, somewhat later, English traders, revived commerce across its waters; and the system of Capitulations (*q.v.*) instituted by the Ottoman Sultans enabled them to do so with some security. For nearly 300 years the Black sea was virtually a Turkish lake. Its sole ingress and egress—the Bosphorus and the Dardanelles—was controlled by the Porte, which levied dues upon all vessels passing the straits.

The situation changed after the accession of Peter the Great to the Russian throne. Peter was the first Russian tsar to appreciate fully the importance of commercial enterprise in national life, and he made every effort to promote Russian trade with the East Mediterranean ports. He further recognized the importance of a strong fleet to protect his traders both from the pirates then infesting the coasts of the Black sea and from possible Turkish depredations in case of war. He constructed arsenals in the Sea of Azov and the Crimea and laid the foundations of Russia's later naval strength in the Black sea. His successors carried on his policy, blending commercial enterprise with the more idealistic ambitions of Pan-Slavism (*q.v.*). As Russia's communications were improved and her commerce developed in the 19th century, the Black sea became more prominent in the eyes of Europe as a highway of commerce. To the corn and similar products of Southern Russia was presently added the oil of the Caspian; and the trade carried by the Black sea increased annually in value until 1914.

Partly to protect this commerce, partly for political purposes, Russia built up a strong Black sea fleet, fear of which, entertained both at the Porte and in Western Europe, particularly in London, led to the imposition of Draconian restrictions upon Russian maritime enterprise in the Treaty of Paris, which concluded the Crimean War (*q.v.*) in 1856. Fourteen years later, however, Russia seized the opportunity presented by the Franco-Prussian War to repudiate these restrictions. From this date until 1914 Russia remained free to develop her naval resources in the Black sea.

During the 18th and 19th centuries Russia, Rumania and Bulgaria took the place of Turkey on the northern and western coasts of the Black sea. The Balkan Wars of 1912-13 slightly extended Rumania's frontier at the expense of Bulgaria; while in 1919 Rumania, besides receiving confirmation of this change, also received Bessarabia (*q.v.*) from Russia: a transference which the Soviet Government refused to recognize as valid. Further east, the Ukraine and Georgia took the place of Russia as riparian States, but as both remained parts of the U.S.S.R., the change was really one of internal organization only.

The Black sea trade suffered severely through the World War and its sequels in Russia. The export of corn from Rumania and Russia ceased altogether for some years. Russia's naval strength was also temporarily reduced, but later steps were taken to restore it.

For the diplomatic history of the Straits and the Dardanelles, see the article STRAITS. (See also RUSSIA; TURKEY; EASTERN QUESTION; CRIMEAN WAR; PAN-SLAVISM.) (I. F. D. M.)

BLACK SNAKE (*Zamenis constrictor*), called also blue racer and hoop snake, a common North American colubrine snake harmless to man, noted for its great speed. It is also an expert climber and swimmer. The black snake is slenderly built and sometimes exceeds 7ft. in length. Western specimens are lighter, but the typical form is black above, dark grey beneath. It feeds on frogs, toads, small snakes, mammals, birds and their eggs, and insects, but the tales of its devouring the rattlesnake and copperhead (*qq.v.*) are fiction. (See SNAKE.)

BLACKSTONE, SIR WILLIAM (1723-1780), the most famous of English jurists, was born in Cheapside on July 10, 1723, the posthumous son of Charles Blackstone, silkman, citizen and bowyer, of London. From Charterhouse school he went at the age of 15 to Pembroke college, Oxford, and was entered at the Middle

Temple in 1741. He was elected in 1744 a fellow of All Souls, devoted himself ardently to the interests of the college, became bursar and prepared his *Essay on Collateral Consanguinity* to defeat the claims of people who were of any degree of kin to the founder, to fellowships, claims which threatened to lower the prestige and efficiency of the foundation of Archbishop Chichele. Called to the bar in 1746, he was chosen by the ancient borough of Wallingford as its recorder in 1749. He tried to practise at the bar during this period, but with so little success that in 1753 he was minded to quit London altogether and devote himself to an academic life. In Michaelmas term 1753 he began to read law lectures at Oxford. His hearers were captivated by the lucidity and charm of his style and by the simplicity with which he presented the subject, slurring over the difficulties and contrarities of the law, giving the whole subject an air of completeness and mutual interdependence as if it were a uniform logical system, suppressing or ignoring the archaic learning, and putting forward the English law as the embodiment of 18th century wisdom.

But from the first he antagonized his rival for the position of the greatest English jurist, Bentham, who seemed to dislike him as much as a man as he mistrusted him as a teacher. Bentham wrote of him that he was "a formal, precise and affected lecturer, just what you would expect from the character of his writings, cold, reserved and wary, exhibiting a frigid pride"; he, however, qualified to some extent this mordant censure when he also wrote:—"correct, elegant, unembarrassed, the style is such as could scarce fail to recommend a work still more vicious in point of *matter* to the multitude of readers. He it is, in short, who, first of all institutional writers, has taught jurisprudence to speak the language of the scholar and the gentleman." In 1758 the lectures were first delivered in their present form. Blackstone having been elected to the newly-founded Vinerian professorship, delivered the introductory lecture "On the Study of the Law" which is prefixed to the first volume of the *Commentaries*. It was some years before the author decided to present the *Commentaries* as a finished work; but notes of the lectures were in circulation, so in Nov. 1765 the first volume appeared, and the three remaining parts were published in the four succeeding years.

On May 5, 1761, he had married Sarah, daughter of James Clitherow of Boston House, Middlesex; on July 28 in the same year the earl of Westmorland, the chancellor of the university, made him principal of New Inn hall.

Professional advancement came side by side with academic. On May 6, 1761, the very day after his marriage, he received a patent of precedence giving him the rank of king's counsel. In 1763 he was made solicitor-general to the queen, the first to hold that office under Queen Charlotte, to whom he dedicated the *Commentaries*; and about the same time he became a bencher of the Middle Temple where his well-known portrait by Gainsborough hangs. In that year his success at the bar led him to resign the professorship and the headship of New Inn hall, two positions which he is said by his anonymous biographer to have intended to use for the foundation of a law school. His career in parliament, to which he was elected for Hindon first (1761), afterwards for Westbury, was somewhat inglorious. He took the ministerial side in the controversy about the Middlesex election, and drew a severe criticism from Junius who boasted that he had answered "Dr. Blackstone" out of his own *Commentaries*, and seems to have completely silenced him.

Blackstone disliked attendance in parliament; this aversion, no doubt, determined him to refuse the solicitor-generalship in 1770 and in February of the same year to accept a judgeship in the court of common pleas. In the ten years of his judgeship he administered the law satisfactorily but attained no special distinction, and his career is not associated with any famous trial. He seems to have given signs of rather premature decay towards 1780, attributed to his sedentary habits and avoidance of physical exercise, and on Feb. 14 of that year he died in London. Two volumes of his *Reports of Decided Cases*, with a brief memoir by his brother-in-law James Clitherow, appeared in 1781, but added little to his fame either as reporter or judge; the reports of his nephew Henry Blackstone are thought better of by the profession.

The Commentaries.—The famous *Commentaries* deserve some detailed account and criticism. Their design is exhibited in his first Vinerian lecture printed in the introduction to them. The author there dwells on the importance of noblemen, gentlemen and educated persons generally being well acquainted with the laws of their country; and his treatise, accordingly, is as far as possible a popular exposition of the laws of England. Falling into the common error of identifying the various meanings of the word law, he advances from the law of nature (being either the revealed or the inferred will of God) to municipal law, which he defines to be a rule of civil conduct prescribed by the supreme power in a State commanding what is right and prohibiting what is wrong. On this definition he founds the division observed in the *Commentaries*. The objects of law are rights and wrongs. Rights are either rights of persons or rights of things. Wrongs are either public or private. These four headings form respectively the subjects of the four books of the *Commentaries*.

Blackstone was by no means a scientific jurist. He has only the vaguest possible grasp of the elementary conceptions of law. He evidently regards the law of gravitation, the law of nature, and the law of England, as different examples of the same principle—as rules of action or conduct imposed by a superior power on its subjects. He propounds in terms the doctrine that municipal or positive laws derive their validity from their conformity to the so-called law of nature or law of God. "No human laws," he says, "are of any validity if contrary to this." His distinction between rights of persons and rights of things, implying, as it would appear, that things as well as persons have rights, is attributable to a misunderstanding of the technical terms of the Roman law. In distinguishing between private and public wrongs (civil injuries and crimes) he fails to seize the true principle of the division. Austin, who accused him of following slavishly the method of Hale's *Analysis of the Law*, declares that he "blindly adopts the mistakes of his rude and compendious model; missing invariably, with a nice and surprising infelicity, the pregnant but obscure suggestions which it proffered to his attention, and which would have guided a discerning and inventive writer to an arrangement comparatively just." By the want of precise and closely-defined terms, and his tendency to substitute loose literary phrases, he falls occasionally into irreconcilable contradictions. Even in discussing a subject of such immense importance as equity, he hardly takes pains to discriminate between the legal and popular senses of the word, and, from the small place which equity jurisprudence occupies in his arrangement, he would scarcely seem to have realized its true position in the law of England. Subject, however, to these strictures, the completeness of the treatise, its serviceable if not scientific order, and the power of lucid exposition possessed by the author demand emphatic recognition. Blackstone's defects as a jurist are more conspicuous in his treatment of the underlying principles and fundamental divisions of the law than in his account of its substantive principles.

Blackstone by no means confined himself to the work of a legal commentator. It is his business, especially when he touches on the framework of society, to find a basis in history and reason for all the most characteristic English institutions. There is not much either of philosophy or fairness in this part of his work. Whether through the natural conservatism of a lawyer, or through his own timidity and subserviency as a man and a politician, he is always found to be a specious defender of the existing order of things. More undeniable than the political fairness of the treatise is its merits as a work of literature. It is written in a most graceful and attractive style, and although no opportunity of embellishment has been lost, the language is always simple and clear. Whether it is owing to its literary graces, or to its success in flattering the prejudices of the public to which it was addressed, the influence of the book in England has been extraordinary. Not lawyers only, and lawyers perhaps even less than others, accepted it as an authoritative revelation of the law. It performed for educated society in England much the same service as was rendered to the people of Rome by the publication of their previously unknown laws. It is more correct to regard it as a handbook of the law for laymen than as a legal treatise; and as the first and

only book of the kind in England it has been received with somewhat indiscriminating reverence. To this day Blackstone's criticism of the English constitution probably expresses the most profound political convictions of the majority of the English people.

Although Blackstone has been much criticized for his superficiality and lack of the historical sense he showed signs of the recognition of the duty of research. His two volumes of *Law Tracts* (1762) give a better impression of him as a student than the more eloquent *Commentaries* and seem to be the outcome of deeper learning and thought. But his inability to place himself in the position of legislators of remote times and his habit of justifying everything as reasonable come out very markedly in his treatment of the famous rule of the *bastard eigné* and *mulier puissné*. In the *Commentaries* themselves his account of the Revolution of 1688 exhibits these defects in the most pronounced form, as in his optimistic description of Edward VI as an amiable prince, in "the short sunshine" of whose reign England enjoyed a peculiar felicity. And his shallowness appears in his justification of the penal laws or apology for them. Instead of condemning them he says: "these laws are seldom exerted in their utmost rigour and indeed if they were it would be very difficult to excuse them." He did, however, go so far as to say in his first edition that he was not sure that some of the secretaries did not hold principles which made them as dangerous as the papists themselves, but in deference to an outbreak of indignation from the secretaries he softened or got rid of this expression in subsequent editions.

In the English law institutional writers are not recognized. The most famous and approved treatises have no such rank as is accorded for instance in Scotland to the works of Stair, of Bell and the like. Consequently Blackstone is seldom or never referred to as an authority. His *Commentaries* are recommended for their literary value, and they have experienced the singular fate of being used as the framework upon which all the additions made to the law by statutes or decisions since his day have been attached for the use of students preparing for examinations, his original text being printed with the new matter interpolated in successive layers, producing in the result text books swollen out of all proportion into portents of ugliness. These monstrosities now, happily, are failing to attract as of old. And there is a reaction in favour of regarding Blackstone's great work from the standpoint of true historical and literary criticism as a complete work of art of the greatest literary merit, inadequate in deep learning, unscientific in arrangement, often mistaken in very elementary matters, but a genuine outcome of 18th century culture and a true exposition of the 18th century standpoint. This reaction is really the just tribute to Blackstone's greatness.

But the fame of Blackstone is greater in the United States than it is in his native land, and bids fair to continue to be, and justly so. After the Declaration of Independence and indeed before, the *Commentaries* were the chief, and in many parts of the country almost the only, source of the knowledge of English law for the great commonwealth of the West. A book which in the old country was and is a text book became in the new an oracle of law, until as years went on the great students of the law in the United States began those deeper studies which have added such wonderful stores of learning and thought to legal literature. But the greatness of Blackstone's renown through two English-speaking continents was most clearly revealed in July 1924, on the memorable joint visit of the American and Canadian law associations to England, when the American lawyers presented to the law courts of London a statue of Blackstone to be executed in marble. The aim of the gift was declared to be "to mark the influence which the great commentator had had over American jurisprudence." It was only the giant plaster model which was unveiled in 1924. The marble itself, the work of Paul Bartlett, who did not live to see the statue in its final perfection, it being finished by the sculptor's wife, was placed in its position in June 1928, in the great hall of the royal courts of justice.

BLACKSTRAP, the crudest molasses of sugar manufacture.

BLACK VARNISH, the general term used to cover a large range of varnishes which have asphalt or bitumen as their essential and characteristic constituent. The different varieties, however, vary greatly in their properties.

The general process used in the manufacture of black varnishes consists in heating asphaltums or pitches, with a proportion of linseed oil and driers consisting of red lead, litharge, and manganese dioxide, at a temperature of about 450° F until the whole becomes stringy. The mass is then allowed to cool sufficiently to enable it to be thinned with turpentine to a suitable consistency.

Coachbuilders' black japan is the highest grade of black varnish manufactured; the best asphaltums and pitches only are used, and a proportion of hard drying copal varnish is incorporated during the process of manufacture.

Berlin black is the name given to a black varnish which dries with a flat or eggshell finish, and is made by adding vegetable black to the ordinary quick-drying black varnishes.

Black stoving or baking enamels are special types of black varnishes used in the cycle and bedstead trades, and are usually applied by dipping and spraying.

BLACK VEIL: see VEIL.

BLACK WATCH, THE (ROYAL HIGHLANDERS), the title of a famous British Highland regiment. The origin of the corps dates from 1729 when a number of loyal Highlanders were embodied forming six independent companies, and constituted a part of the regular army. They continued to wear the dress of their country, a tartan of sombre appearance which gained for them the gaelic appellation of "Freicudan Du" (or "Am Freicadan Dubh"), i.e., "Black Watch," in contradiction to regular troops who wore scarlet coats, waistcoats and breeches, and were called "Seidaran Dearag," or "Red Soldiers." These companies were first employed in enforcing the disarming act in Scotland which required a constant *watching* of rival clans to prevent plunder and reprisals. The *Black Watch* were known by that title for a number of years, before it was changed to the "Highland Regiment." In 1751 they were the "42nd," or the "Highland Regiment," but later reverted to their original title.

BLACKWATER, the name of several streams in England, Scotland and Ireland. The Blackwater in Essex rises near Saffron Walden and flows about 40m. to the North Sea. The Blackwater in Southern Ireland rises in the border-hills of Cork and Kerry, and flows east to Cappoquin, where it turns abruptly southward and discharges through an estuary into Youghal bay.

BLACKWATER FEVER. So far this disease, which occurs in all tropical countries and occasionally elsewhere, and is often classed with malaria, has defied the efforts of research to trace its cause. Its geographical distribution covers tropical Africa, where it is perhaps most prevalent, parts of Asia, the West Indies, the southern United States, Greece, Sicily, and Sardinia. Its range is not co-extensive with malaria since it is found in places where malaria is unknown or infrequent. According to Webster it is "a malarial fever marked by bloody urine." It is characterized by irregular febrile paroxysms, accompanied by rigors, bilious vomiting, jaundice and haemoglobinuria, the victim being anaemic in proportion to the severity of the case. The kidneys are clogged, the urine being more discoloured in some cases than in others.

The association of blackwater fever with malaria (*q.v.*) is a question which still divides expert opinion. Dr. J. G. Thomson in his *Report on Southern Rhodesia* has pointed out that blackwater fever occurs principally among persons living in houses unprotected and careless about mosquito nets, and he supports his case by statistics given by Stephens, Nakayawi and Hoctori with percentages of 73, 85 and 96 in which malarial parasites were found in blackwater fever cases. Some authorities, including Koch, have believed that excessive use of quinine taken to combat malaria was responsible. If that were correct, one would expect

blackwater fever to be regularly prevalent in malarial countries and more or less co-extensive with the use of quinine, which is not the fact. Moreover Thomson says cases of blackwater fever have occurred among Europeans who are known never to have taken quinine. The modern school of tropical parasitology rejects both theories, and regards blackwater fever as a specific disease due to a protozoal parasite akin to that which causes the redwater fever of cattle.

Yet Dr. Andrew Balfour, the great authority on hygiene, in his *Health Problems of the Empire* (British Empire Series), argues that the view now "most generally held" is that blackwater fever is "merely a concomitant of malaria" and continues: "If so, it is a most serious complication, which has slain many a pioneer of empire. Even if, as some believe, blackwater fever is a disease *sui generis* and due to a parasite of its own, yet there can be little doubt that it is in some way or other associated with malarial infection. Perhaps malaria renders the red blood cells more fragile so that they are readily acted upon by some other poison, and so yield up their colouring matter, which, set free in the blood, is voided in the urine. It colours this secretion a shade of red, varying from that of a light claret to that of dark port wine, and it is this change, striking and fear-inspiring, which has given the condition its name of blackwater."

See J. G. Thomson *Preliminary Report on the Results of Investigations into the Causation of Blackwater Fever in Southern Rhodesia* (1923). (C. H.; E. S.)

BLACKWELDER, ELIOT (1880—), American geologist, was born in Chicago, Ill., on June 4, 1880. He graduated at the University of Chicago in 1901 and in 1914 received the degree of doctor of philosophy from that institution. From 1902 until 1919 he was instructor or professor in the universities of Chicago, Wisconsin and Illinois and was a member of the U.S. geological survey. In 1922 he became professor of geology in Stanford university.

Among his publications are *Elements of Geology* (with H. H. Barrows, 1911) and *Regional Geology of the United States* (1912).

BLACKWELL, ELIZABETH (1821-1910), the first woman doctor of medicine, was born at Counterslip, Bristol, Feb. 3, 1821. The daughter of a sugar refiner, who emigrated to New York in Aug. 1832, Elizabeth sought admission in vain to the medical schools of Philadelphia and New York, and eventually secured admission to the medical class at Geneva, Western New York State, graduating M.D. in 1849. She then came to England, and after studying at St. Bartholomew's Hospital and on the continent she returned to America, and in spite of much opposition, established in New York in May 1857, a hospital entirely staffed by women and in due course succeeded in founding there a full course of medical education for women. Sophia Jex-Blake was among the first students. Dr. Blackwell returned to England in 1857 to practise. By a bill passed in 1858 a General Medical Council was established to keep a register of duly qualified medical practitioners. Dr. Blackwell had practised in London some little time before the register was compiled, and when she applied for her name to be included, it was found she could not be refused, and thus an important precedent was established. She died at Hastings on May 31, 1910.

See her *Pioneer Work: Autobiographical Sketches* (1895).

BLACKWELL, THOMAS (1701-57), Scottish classical scholar, was born at Aberdeen on Aug. 4 1701, and was principal of the Marischal college from 1748 till his death in 1757. His first work, *An Inquiry into the Life and Writings of Homer*, published anonymously in 1735 (reprinted 1736), shows considerable research but lacks method. His other works were *Letters Concerning Mythology* (1748), and *Memoirs of the Court of Augustus* (1755-64).

BLACKWELL, a city of Kay county (Okla.), U.S.A., midway between Oklahoma City and Wichita, 15m. from the Kansas State boundary. It is on Federal highway 177; the Frisco and the Santa Fe railways; and the lighted airway from Chicago to Dallas. It has an intermediate landing field. The population in 1927, according to a special census under Federal supervision, was 11,878. Blackwell is surrounded by productive gas and oil-

fields. Stock-raising and agriculture are also important local industries. It has grain elevators, oil refineries, a zinc smelter, and glass factories. It was settled and incorporated in 1893, following the opening of the Cherokee Strip.

BLACKWOOD, WILLIAM (1776-1834), Scottish publisher, founder of the firm of William Blackwood and Sons, was born of humble parents at Edinburgh on Nov. 20, 1776, and died there on Sept. 16, 1834. In 1804, he opened a shop in South Bridge street, Edinburgh, for the sale of old, rare and curious books. He undertook the Scottish agency for John Murray and other London publishers, and gradually drifted into publishing on his own account, removing in 1816 to Princes street. On April 1, 1817, was issued the first number of the *Edinburgh Monthly Magazine*, which, on its seventh number, bore the name of *Blackwood's* as the leading part of the title. "Maga," as this magazine soon came to be called, was the organ of the Scottish Tory party, and round it gathered a host of able writers. William Blackwood was succeeded by his two sons, Alexander and Robert, who added a London branch to the firm.

A younger brother, JOHN BLACKWOOD (1818-1879), succeeded to the business; four years later he was joined by Major William Blackwood, who continued in the firm until his death in 1861. In 1862 the major's eldest son, William Blackwood (b. 1836), was taken into partnership. It was in the pages of John Blackwood's magazine that George Eliot's first stories, *Scenes of Clerical Life*, appeared. He also inaugurated the "Ancient Classics for English Readers" series. On his death Mr William Blackwood was left in sole control of the business. With him were associated his nephews George William and J. H. Blackwood, sons of Major George Blackwood, who was killed at Maiwand in 1880.

See *Annals of a Publishing House; William Blackwood and his Sons* . . . (1897-98), the first two volumes of which were written by Mrs. Oliphant; the third, dealing with John Blackwood, by his daughter, Mrs. Gerald Porter.

BLADDER, the membranous sac in animals which receives the urine secreted from the kidneys. The word is also used for any similar sac, such as the gall-bladder, the swim-bladder in fishes, or the small vesicle in various seaweeds.

BLADDER AND PROSTATE DISEASES. (See also URINARY SYSTEM and UROLOGY.)

DISEASES OF THE BLADDER

Cystitis, or inflammation of the bladder, which may be acute or chronic, is due to the invasion of the mucous lining by micro-organisms, which gain access either from the urethra, the kidneys or the blood-stream.

Any condition leading to disturbance of the function of the bladder, such as enlargement of the prostate, stricture of the urethra, stone, or injury, may cause cystitis by preparing the way for bacillary invasion. The bacilli of tuberculosis and of typhoid fever may cause it by passing into the bladder from the kidneys with the urine, or invade it by the urethra. Frequently bacteria are introduced by way of catheterization. The first effect of inflammation is to render the bladder irritable, so that as soon as a few drops of urine have collected, the individual has intense or uncontrollable desire to micturate. The effort may be very painful and may be accompanied by bleeding from the overloaded blood-vessels of the inflamed membrane. In addition to blood, pus is likely to be found in the urine, which by this time is alkaline and ammoniacal, and teeming with micro-organisms. As regards *treatment*, bed, hot baths, milk diet and abstinence from alcohol are indicated, while frequent washing out of the bladder with weak antiseptics is necessary if the urine is foul.

Chronic cystitis is the condition left when the acute symptoms have passed away, but it is liable at any moment to resume the acute condition. If the cystitis is very intractable, refusing to yield to hot irrigations, and to washings with nitrate of silver lotion, it may be advisable to open the bladder from the front, and to explore, treat, drain and rest it.

Tuberculous cystitis is a late manifestation of tuberculosis in kidney, prostate or epididymis and is very intractable.

Calculi and Gravel.—Uric acid is deposited from the urine either as small crystals resembling cayenne pepper or, in combination with soda and ammonia, as an amorphous "brickdust" deposit, which, on cooling, leaves a red stain on the bottom of the vessel, soluble in hot water. These substances are derived from the disintegration of nitrogenized food taken in excess of demand, and from the breaking down of the human tissues. They occur therefore in fevers, in wasting diseases, and in the normal subject after excessive muscular exercises, especially if accompanied with much perspiration. If the uric acid debris continue to be excessive, renal or vesical calculi may be formed. In an alkaline urine, *e.g.*, where a stone has led to cystitis, phosphates of ammonia and magnesium are deposited.

A stone in the bladder causes a constant desire and need for micturition and the urine contains mucus and blood. Lastly, cystitis occurs, and the urine contains foetid pus. A stone in the bladder gives rise to pain at the end of the penis, and it is apt suddenly to stop the flow of urine during micturition.

Treatment.—Usually the stone is crushed within the bladder by a lithotrite and the fragments flushed out through a hollow metal catheter. But if the stone is very hard or large or other conditions contra-indicate, lithotrity must be replaced by a cutting operation (*lithotomy*).

The treatment of vesical calculi by other means than operative surgery is of little value. Attempts to dissolve them by internal remedies, or by the injection of chemical agents into the bladder have invariably been found worthless for removing calculi once actually formed.

Rupture of the bladder may be caused by a kick or blow over the upper part of the abdomen, or by a wheel passing over it; or it may be a complication of fracture of the pelvis. The great danger is supervention of septic cellulitis, but if thorough drainage and asepsis be carried out and the rent be sewn up recovery is not impossible.

New Growths.—The most frequent non-malignant growth is "villous tumour" which springs from the floor of the bladder and floats in the urine like seaweed. When portions of the filaments are broken off the urine contains blood. The growth may be removed surgically, but often recurs (see TUMOURS).

Malignant disease of the bladder is almost always the warty form of cancer known as epithelioma. It springs as a sessile growth from the mucous membrane of the floor near the opening of one of the ureters, and is one of the severest forms of cancer owing to the local changes it produces and its tendency to cause a fistulous opening between bladder and rectum in the male or vagina in the female. Though it may be primary, cancer of the bladder is usually due to extension of growth from the uterus or rectum.

Hypertrophy and Dilatation.—When there is long-continued obstruction to the flow of urine, as in stricture of the urethra, or enlargement of the prostate, the bladder-wall becomes much thickened, the muscular fibres increasing both in size and number. Hypertrophy may be accompanied by *dilatation* when the voiding of contents is not complete and is of long standing, when obstruction is complete, dilatation alone occurs.

Paralysis of the bladder may result from injuries whereby the spinal cord is lacerated or pressed upon. The result may be either retention or incontinence of urine, sometimes there is at first retention, which later is followed by incontinence. Paralysis is also met with in certain nervous diseases, as in locomotor ataxia, and in various cerebral lesions, as in apoplexy.

Atony of the bladder is a partial paralysis. It is due to a want of tone in the muscular fibres, and is frequently the result of over-distension, such as may occur in cases of enlargement of the prostate. The patient is unable to empty the bladder, and the condition of atony gets increasingly worse.

Incontinence of urine may occur in the adult or in the child, but is due to widely different causes in the two cases. In the child it may be simply a bad habit, but more frequently there is a want of control in the micturition-centre, so that the child passes its water unwittingly, especially during the night. In adults the water which passes is the overflow from a too full reservoir.

It is usually caused by an obstruction external to the bladder, e.g., enlarged prostate, calculus, or stricture of the urethra. In the child an attempt must be made to improve the tone of the micturition-centre by the use of belladonna or strychnine internally, and of a blister or faradism externally over the lumbar region, and every effort should be made to train the child to pass water at stated times and regular intervals. In the adult the cause which produces the over-distension must be removed if possible; but, as a rule, the patient has to be provided with a catheter, which he can pass before the bladder has filled to overflowing.

Retention of urine may occur in paralysis of the bladder, or in conditions where the patient is suffering from an illness which blunts the nervous sensibility, such as apoplexy, concussion of the brain, or typhoid fever. It is, however, more commonly due to obstruction anterior to the bladder, as in stricture of the urethra or enlargement of the prostate.

Surg.*, xiii., p. 78 (1925-26); H. H. Young and D. M. Davis, *Practice of Urology* (1926).

DISEASES OF PROSTATE GLAND

The prostate gland may become acutely inflamed as the result of the backward extension of gonorrhoeal inflammation of the urethra; it may also be attacked by the germs of ordinary supuration or by *B. tuberculosis*. As a result micturition and defaecation are difficult, painful or impossible. If abscess forms, it should be incised from the perineum; if allowed to run its course it may burst into the bladder, urethra or rectum, and set up serious complication. *Chronic prostatitis* is a legacy from gonorrhoea. The enlargement gives a feeling of weight and fullness in the perineum, irritability of the bladder, and a urethral discharge.

Enlargement of the prostate exists in a considerable proportion of men of about 60 years of age and onward. It consists in formation of an adenoma in the gland or overgrowth of the normal muscular, glandular or fibrous tissue. In either case the passage of urine is impeded, hypertrophy and dilatation of bladder supervene and the organ cannot be emptied completely. If putrefactive organisms gain access to this stagnant urine, cystitis and perhaps renal disease and stone may follow. The seriousness of enlargement of the prostate depends mainly upon the inability of the patient to empty his bladder completely. Surgical removal of the enlarged mass is successful in many cases.

Malignant disease of the prostate is distinguished from senile enlargement by the rapidity of its growth, by the frequency of the bleeding which is associated with the introduction of a catheter, and by the marked wasting which the individual undergoes. Unfortunately, by the time that the cancerous nature of the disease is definitely recognized, the prospect of relief being afforded by operation is small. Some success has followed radium treatment.

BLADDER-WORM: see TAPEWORM.

BLADDER-WORT, a submerged water plant, *Utricularia vulgaris*, with finely divided leaves upon which are small bladders provided with trap-doors which open only inwards. When small crustaceans and other aquatic animals touch the front of the bladder it alters its shape and they are sucked in and are unable to escape. The products of the decay of the organisms thus captured are absorbed by star-shaped hairs which line the interior of the bladder. In this way the plant is supplied with additional nitrogenous food. Bladder-wort bears small, yellow, two-lipped flowers on a stem which rises above the surface of the water. It is found in pools and ditches in the British Isles, and is widely distributed in the north temperate zone. The genus contains about 200 species in tropical and temperate regions, some 20 of which occur

in North America. (See INSECTIVOROUS PLANTS.)

BLADES, WILLIAM (1824-90), English printer and bibliographer, was born at Clapham, London, Dec. 5 1824, and died at Sutton, Surrey, April 27 1890. In 1840 he was apprenticed to his father's printing business in London, and was subsequently taken into partnership. His *Life and Typography of William Caxton, England's First Printer*, was published in 1861-63, and the conclusions which he set forth were arrived at by a careful examination of types in the early books, each class of type being traced from its first use to the time when, spoiled by wear, it passed out of Caxton's hands. Some 450 volumes from the Caxton Press were thus carefully compared and classified in chronological order.

BLAENAFON or **BLAENAVON**, urban district, Monmouthshire, England. Pop. (1921) 12,460, in a cul-de-sac on the north-east edge of the South Wales coalfield, near the source of the Afon Llwyd. Owing to its situation on the ironfield of the northern outcrop of the coalfield, Blaenafon, like Merthyr and Dowlais, became an important iron smelting region soon after the Industrial Revolution, famous for its iron, steel and tinplate works.

lic, on the left bank of Amur river, near its confluence with the Zeya. Lat. 50° 20' N, Long. 127° 30' E. Pop. (1926) 57,500. It was established in 1856 by Muravieff, and re-named by him in 1858 after the successful treaty of Aigun. The town is a natural halting place for steamers, the river becoming impassable above it, but flowing with a gentle gradient (400ft. in 1,300m.) below it. Steamers may turn off here and traverse the Zeya river for 300m. to the gold mines. The trade is mainly in tea, cattle, grain and

gold and in the products of its flour mills and ironworks. The town has educational institutes, a museum, a public library and an opera house.

(2) A monastery near Nizhni-Novgorod (*q.v.*).

(3) A town in the Ufa province of the Bashkir Autonomous Socialist Soviet Republic. Lat. 55° 0' N., Long. 56° 0' E. Pop. (1926) 6,899.

BLAIKIE, WILLIAM GARDEN (1820–1899), Scottish divine, was born on Feb. 5 1820, at Aberdeen, and was one of the 474 ministers who signed the deed of demission and gave up their livings at the time of the Disruption. He was Free Church minister at Pilrig, between Edinburgh and Leith, from 1844 to 1868, when he became professor of apologetics and pastoral theology at New college, Edinburgh. In 1870 he was one of two representatives chosen from the Free Church of Scotland to attend the united general assembly of the Presbyterian Churches of the United States. A prolonged visit to America, followed by a similar tour in Europe, fitted him to become the real founder of the Presbyterian Alliance. In 1892 he was elected to the chairmanship of the general assembly, the last of the moderators who had entered the church before the disruption. In 1897 he resigned his professorship, and died on June 11 1899.

Blaikie was an active and intelligent temperance reformer. He raised £14,000 for the relief of the Waldensian churches. Among his works is *After Fifty Years* (1893), an account of the Disruption Movement in the form of letters of a grandfather.

BLAINE, JAMES GILLESPIE (1830–1893), American congressman, U.S. senator and secretary of State, one of the succession of Americans whose ability and political acumen have led them close to the presidency of the United States, only to be defeated. In American political history Blaine was known, devotedly or derisively, as "the Plumed Knight," from an oratorical metaphor of Robert J. Ingersoll (*q.v.*), American orator and agnostic, in his presentation of Blaine for the nomination to the presidency in the Republican convention in 1876.

James Gillespie Blaine was born on Jan. 31, 1830, in West Brownsville, Pa., the son of Ephraim Lyon Blaine and Maria Gillespie (Blaine). He was the great-grandson of Col. Ephraim Blaine, commissary general of the American Revolutionary army during the Revolutionary War. After graduating from Washington college in Washington, Pa., in 1847, Blaine engaged in teaching for six years, first as an instructor in mathematics in a military school at Blue Lick Springs, Ky., and later in the Pennsylvania institution for the instruction of the blind at Philadelphia, Pa. He was married, in 1850, to Harriet Stanwood, and in 1854 moved to Augusta, Me., the capital of that State, and Mrs. Blaine's native city. He became editor-in-chief and part owner of *The Kennebec Journal* and from this date, 1854, onward devoted himself to journalism and politics. In 1856 he attended the first national convention of the new Republican party in Philadelphia and in 1858 was elected on the Republican ticket to the Maine State legislature. A student of parliamentary usage, he was elected, after two years' service as a member, to the office of speaker of the house of representatives of the Maine legislature. This honour he held for two subsequent years, until his election to the 38th Congress of the United States in 1862.

Blaine served in the U.S. House of Representatives from Dec. 1863 to Dec. 1876, and was then in the U.S. Senate until 1881 when he resigned to become secretary of State. In 1869, he was elected speaker of the House of Representatives, at that time one of the most powerful positions in the American Government, in which capacity he served for three terms or six years. In 1876 Blaine was the leading candidate for the Republican nomination for the presidency and entered the convention with very nearly enough votes for the nomination on the first ballot. The Democrats had previously charged him with using his high office as speaker of the House of Representatives to obtain a personal profit through the sale of bonds of the Little Rock and Fort Smith railway, and this issue was brought up in the nominating convention of 1876 and clearly militated against Blaine's obtaining the additional votes needed for nomination. In addition, Blaine suffered a sunstroke on the eve of the convention and rumours of his

illness, even of his death, were circulated freely. After continuous balloting, Rutherford B. Hayes was nominated by a majority of 28 votes over Blaine.

Blaine entered the U.S. Senate as a result of an executive appointment to fill a vacancy. His subsequent election for the succeeding six-year term is unique in American history in that he was chosen by the unanimous vote of the State legislature, Republicans and Democrats uniting in his choice. In 1880 Blaine was again a candidate for the presidential nomination but was defeated by his friend, James A. Garfield (*q.v.*). Blaine, however, wholeheartedly supported Garfield and was active throughout the campaign. Upon President Garfield's inauguration Blaine was named secretary of State, resigning from the Senate to accept. During the brief period of Garfield's administration, prior to his assassination on July 2, 1881, Blaine had time to plan and draw up invitations for the Latin-American countries to meet with the United States in Washington the following year, for the purpose of discussing, only, the methods of preventing war between the nations of America. At that time Chile, Peru and Bolivia were engaged in the bloody war of the Pacific; Guatemala was fearful of invasion from Mexico; Brazil and Uruguay, Argentina and Brazil, and Argentina and Chile were believed to be in danger of war. The invitation was actually issued by Chester A. Arthur (*q.v.*), who succeeded Garfield, but following Blaine's retirement from the office of secretary of State, his successor (Frederick L. Frelinghuysen) withdrew the invitations and the proposed Pan-American conference was postponed until Blaine again became secretary of State under President Harrison in 1889. In his few months as secretary of State in 1881, Blaine also took up with Great Britain the question of the modification of the Clayton-Bulwer treaty of 1850 (which provided that Great Britain and the United States should have equal control of any canal across the Isthmus of Panama). Blaine's diplomacy sought to reach an agreement by which an entirely American canal might be built under a modification of the Treaty of 1850. His plans in this matter were not to be realized until the Hay-Pauncefote treaty, 20 years later.

Blaine was finally nominated for the presidency at the Republican convention in 1884. His campaign was brilliant and his victory was expected until the very last days preceding the election when he began "storming" the State of New York, the native ground of his Democratic opponent, Grover Cleveland. The presidency slipped from Blaine's grasp, in the end, by the loss (by 1,149 votes) of the State. Blaine, himself, as well as many others, attributed his defeat to the loss of the Roman Catholic vote following the enunciation of the phrase, "Rum, Romanism and Rebellion" used by the Rev. Dr. Samuel D. Burchard in describing the Democratic party in a speech made in Blaine's presence at the Fifth Avenue hotel, New York city, on Oct. 29. Blaine in his reply failed to disavow Mr. Burchard's allegation and the opposition made ready capital of Blaine's alleged endorsement of the bracketing of Roman Catholicism with the liquor traffic and sedition.

For a time after this Blaine and his family lived in Europe and he declined to have his name used in connection with the presidential nomination in 1888. He returned to the United States to take active part in the electoral campaign of Benjamin Harrison and following Harrison's election was again appointed secretary of State. In the four years that followed, Blaine brought into realization his broad foreign policy, with particular reference to Latin-America. He called what was later to be known as the first Pan-American conference to meet in Washington in 1889 and laid the foundations for the ideals of arbitration between the American countries and for the type of commercial activities which have characterized the Pan-American movement since that date. Blaine sought common American support of measures encouraging the building of a railway for the length of the American hemisphere; for the signing of copyright and trade-mark agreements, a uniform system of customs dues, weights and measures and currency, and finally an agreement looking toward the arbitration of all international questions between the American nations.

From the beginning of his career in Congress Blaine had been an enthusiastic advocate of reciprocity between the United States

and Latin-American countries. The Pan-American congress of 1889 placed itself on record for reciprocity between all the countries of the Western hemisphere and Blaine definitely shaped his foreign commercial policies on this foundation. The period was one of tariff controversies, the Democrats being insistent upon "free trade" and the Republicans on a high tariff. Blaine, while an ardent Republican and supporter of Republican tariff principles, held to the ideal of reciprocity with the neighbouring nations of Latin-America as a matter of foreign policy and as of great economic value to the American manufacturing interests which were being protected by the high tariff against European manufactured goods.

Blaine faced, during his second term as secretary of State, the strained relations of the United States and Chile, growing out of the killing of American sailors in the streets of Valparaiso in 1891. The issue was a complicated one, and a question of policy as well as of diplomatic arrangement. The attack on the American sailors was in part due to the memory of Blaine's alleged partisanship for Peru in the war on the Pacific during his previous service as secretary of State in 1881. The first lively controversies on seal fishing in Bering sea, which were later settled by arbitration between Great Britain and the United States, came up under Blaine's secretaryship in Harrison's administration. He prepared the ground at that time for the later adjustment of the seal fisheries issue, one of the notable examples of successful arbitration of a highly complicated economic issue. Blaine resigned as secretary of State under President Harrison on June 4, 1892, as a direct result of the unauthorized activity of his partisans, who sought to use his name in the Republican convention of that year in the face of his failing health and in spite of his membership in the cabinet of President Harrison who was himself a candidate for re-election. When Blaine resigned he had been absent from his office almost continuously for many months owing to his poor health, and following a series of deaths in his immediate family in which he lost two sons and a daughter in less than two years, Blaine himself died at Washington, D C., on Jan. 27, 1893.

BIBLIOGRAPHY.—Mrs. James G. Blaine (Harriet Stanwood Blaine), *Letters*, 1908, Blaine's own autobiography, *Twenty Years in Congress*, 1884 and 1886, and the *Lives* by R. H. Conwell, 1884; Gail Hamilton (Mary Abigail Dodge), 1895; and Edward Stanwood, 1905, are the best. The letters to Warren Fisher are published in full in *Mr. Blaine's Record*, published by the Committee of One Hundred in Boston, and the *Congressional Record* for his long service there, the annual publications of *Foreign Relations of the United States*, compiled by the department of State for the time of his two services as secretary of State, as well as the unpublished files of the department of State which are accessible to historians, contain a vast amount of source material which has never been adequately studied. See also Gamaliel Bradford, *American Portraits, 1875-1900* (Boston, 1922); Tyler, Alice Felt, *The Foreign Policy of James G. Blaine* (University of Minnesota Press, Minneapolis, 1928). (W. TRO)

BLAINVILLE, HENRI MARIE DUCROTAY DE (1777-1850), French naturalist, was born at Arques, near Dieppe. In 1812 he was aided by Cuvier to obtain the chair of anatomy and zoology in the Faculty of Sciences at Paris, but subsequently an estrangement grew up between the two men and ended in open enmity. In 1825 Blainville was admitted a member of the Academy of Sciences; and in 1830 he was appointed to succeed J. B. Lamarck in the chair of natural history at the museum. Two years later, on the death of Cuvier, he obtained the chair of comparative anatomy, which he held for 18 years.

He wrote *Prodrome d'une nouvelle distribution méthodique du règne animal* (1816); *Ostéographie ou description iconographique comparée du squelette, etc.* (1830-64); *Faune française* (1821-30); *Manuel de malacologie et de conchyliologie* (1825-27); *Histoire des sciences de l'organisme* (1845).

BLAIR, FRANCIS PRESTON (1791-1876), American journalist and politician, was born at Abingdon, Va., on April 12, 1791. He graduated from Transylvania university in 1811, took to journalism, and was a contributor to Amos Kendall's paper, the *Argus*, at Frankfurt. In 1830, having become an ardent follower of Andrew Jackson, he was made editor of the Washington *Globe*, the recognized organ of the Jackson party. In this capacity, and as a member of Jackson's "Kitchen Cabinet," he long exerted a powerful influence. The *Globe* was the administration organ un-

til 1841, and the chief Democratic organ until 1845. Blair ceased to be its editor in 1849. In 1848 he actively supported Martin Van Buren, the Free Soil candidate, for the Presidency, and in 1852 he supported Franklin Pierce, but soon afterwards helped to organize the new Republican Party and presided at its preliminary convention at Pittsburgh, Pa., in Feb. 1856.
